The important pathological findings of this case included almost complete destruction of the corpus callosum from thrombosis of the anterior cerebral arteries; an area of softening in the left inferior parietal extending to the body of the angular gyrus; lesion in the left frontal under Broca's area; and an area of softening in the right side of the brain involving the angular gyrus. It was remarkable that the central convolutions on the left side were intact, as were their projection tracts. On the other hand, the central areas were largely isolated from the rest of the brain by the lesions of the corpus callosum, frontal and parietal areas.

Liepmann places the most importance on lesions of the left parietal region in the causation of apraxia. He also considers that, for limb movements as well as language functions, the left or major side of the brain takes a leading part, in the direction of movements executed by the right side of the brain through the medium of the corpus callosum, and that movements of the left side of the body executed by the right cerebral hemisphere, are to a certain degree directed by the left hemisphere through the corpus callosum.

CLASSIFICATION OF APRAXIA

Liepmann's classification of apraxia has been commonly accepted and may be outlined as follows:

Definition.—Apraxia is the inability to perform purposeful movements, the inability not being due to paralysis, ataxia, agnosia, or general physical or psychic impairment.

Ideational Apraxia.—This type is manifested by confusion of movements, omission of certain important parts of a series of movements, perseveration, inverted order in the series, etc. This is due to a lesion which disturbs the ideational plan, and is characterized by disturbance of attention, memory, temporal and spatial relationship, etc., in the ideational field. There is frequently a memory defect giving rise to symptoms of apparent absentmindedness. Symptoms of agnosia are common, as are those of aphasia or paraphasia. Coördination of movement is good. Imitation of movement is fair because it is easy for the patient to follow a plan furnished from the outside.

Ideokinetic Apraxia.—In this form of apraxia the sequence of activity is normal up to and including the formation of the ideational plan, but the translation of the plan into movement is defective. It is manifested by a total inability to perform an act, or by performing some act which is not intended. Purposeless movements are frequently observed which suggest an element of ataxia in the picture.

Limb Kinetic Apraxia.—This type is observed to result from a disturbance in the kinetic patterns in or near the motor area, and may result from a lesion of the motor area not sufficient to cause paralysis. It is manifested by inability to perform skilled movements. The sequence and general form of the movements appear normal, but they are awkward, as if being done for the first time.

Sympathetic Apraxia.—This is due to lesions of the corpus callosum interfering with the influence of the left cerebrum in directing movements executed by the right side. This is most characterized by awkwardness of movement, and commonly by inversions of movement of the type of mirror-writing.

REPORT OF CASES

CASE 1.—H. P. C. Patient first seen February 18, 1927. He gave a history of periodic headaches for years, usually most marked in the left frontal region. Headaches were attributed to overeating, and were relieved by a physic. They were not associated with nausea or vomiting, and have not increased with the years. In 1923 he first noted difficulty in making out a check. Since then he has had increasing difficulty in remembering recent events, becomes confused in making out accounts, and is obviously growing worse. In December, 1926, he had an operation by Dr. C. Rey,-nolds, left temporal craniotomy, in which it was stated that a subdural collection of fluid was found. The brain was said to have been depressed "one and one-half inches on the left side," with changes in the vessels and cortex. Following the operation some improvement was noted for a few months; then he became worse again and now (February 18, 1927), is worst of all. He is awkward in dressing and in eating. He says things seem to be "out of line." His memory for remote events is good, but for recent events poor. If his coat sleeve is wrong side out he has difficulty in fixing it. He has had difficulty in putting coat on coat hanger only during the last few months. On attempting to place coat on hanger, patient pushes one end of it into one sleeve, but fails to understand what to do with the other end. After puzzling over it for two or three minutes, he throws coat and hanger down with impatience. His wife states that many times failure is not noticed by patient. He shows annoyance and depression after failure, especially when observed. He takes off and puts on shoes and socks without difficulty. His wife states that his gait and posture have changed altogether. He walks with forward stoop, swings arms and legs in different manner. He reads slowly, hesitating, stumbling, mispronouncing occasional long words. Wife states: "He sometimes says, "I never saw that word before," even of words he has known all his life. The patient often has a thought or an idea he wishes to express, and loses it before he can say what he wants to. Facility in solving problems, even the simplest, is lost. Numbers are almost totally confused. He can add 3 and 2, but says 7 plus 3 are 12, and 4 plus 2 are eight. He failed completely to add 67 and 23. He counts well to ten and more. Five in one hand and four in the other are not added correctly; he says the answer is 7.

Examination on February 18, 1927, showed cranial defect of left frontal and parietal region, depressed and pulsating (never has bulged). Visual fields are good to rough tests. Eye-grounds are normal. There is no diplopia or nystagmus. Pupils are of normal size, equal and regular, and react normally to light and accommodation. There is a lag of facial movements on the right. There is loss of many skilled movements. Gait and posture show stooping, and swinging of arms and legs. Romberg is negative. There are no tremors and no athetosis. The patient is right-handed. The tendo Achillis reflexes are absent. Plantars are normal bilaterally. Consciousness is clear. Memory, orientation and attention poor. He shows some loss of emotional control and much anxiety, with impatience at failures.

March 18, 1929.—Reëxamination: Patient has failed in memory for recent events to point of forgetting all details of important business matters. He is also unable to sign his name to business papers, though he can sign on unimportant papers. Effort to write other words usually fails. He works about home and the garden. Eats and sleeps well, and has no particular discomfort. Eye-grounds are flat, veins full, arteries small, nerve margins clear, discs a little pale.

December 14, 1929.—Reëxamination: The patient is robust in appearance. Sensory aphasia is incomplete. Alexia. Speech: Jargon tendency, with good enunciation, but often mumbles. Apraxia: Marked. Reflexes: Biceps moderate, knee-jerks hyperactive, tendo Achillis not elicited. Marked increase in muscle tone. Can use spoon in eating with some difficulty. Garden rake he is apt to get upside down. General health is good. Coördination fair in walking, standing, sitting, etc. No. weakness or paralysis of any extremities. No ataxia. Pupils equal and react to light. No choked disc. Pulse full, regular, 75.

This case presents a rather marked picture of ideational apraxia with additional symptoms of mental impairment, inability to calculate, marked aphasic disturbance with jargon speech, and semantic defects.

* * *

CASE 2.—Mrs. M. W. came under observation October 24, 1933. Patient was forty-five years of age. She gave a history of having had sudden right hemiplegia with loss of speech at the age of thirty-one. She made fairly good recovery within one month. Again at the age of forty-three she suddenly lost the use of the right arm, and was unable to swallow or speak for a few days. Since then there has been some stammering and impairment in the use of the left arm, as well as the right.

Present trouble began on October 3, 1933, with an acute or sudden illness. Patient became partially unconscious, with stentorous breathing, and was unable to swallow. She could not talk, open the mouth, or move the tongue.

Examination made three weeks after the onset. At that time the patient had been tube-fed daily for three weeks. She was conscious, alert, quick to understand spoken language, and could read fluently and understandingly, but could could not speak a word. All extremities are moved freely. The patient was able to walk and used her right hand in writing, although what she wrote was almost illegible; she is normally right-handed. Face movements were somewhat impaired, more so on the right. Extra-ocular movements were free in all directions. Voluntary movements of frontals and orbiculars good, but face, tongue and jaw movements were almost nil. The patient was unable to move the jaw or lips, or protrude the tongue. She swallowed with much difficulty, and only a teaspoon of liquid at a time. In smiling, the face movements were fairly active and symmetrical. Patient was able to blow out a match held several inches in front of her face. Tendon reflexes were somewhat hyperactive in all extremities, more so in the arms, and most in the right arm. No pathological toe-reflexes on either side. Visual fields were normal. Astereognosis of the right hand; left normal.

Last observation was made on September 17, 1934. Patient had improved gradually, and was married on February 14, four months after the onset, although she was still unable to talk. She was able to vocalize vowels, and still wrote with her right hand, but chirography was minute and indistinct. Formerly an experienced typist, she was asked to write on the typewriter. Although she appeared familiar with the instrument and wrote fairly quickly, most of the words were misspelled and letters reduplicated. Left hand was used fairly well, but the right hand failed to hit the right keys. Husband stated that patient used right hand much less awkwardly than a few months ago. She has gained in weight and feels well. She goes down town alone, attends the movies, etc.

The apractic symptoms in this case were of the ideomotor type. In addition to apraxia of the right hand there was apraxia of the mouth. The inability to swallow and inability to talk were also probably apractic symptoms. Symptoms other than apraxia included astereognosis of the right hand and a degree of mental impairment and personality changes, although she was able to read and understand spoken language fairly well.

* * *

Case 3.—Mrs. E. C. G., fifty-nine years of age. Had toxemic puerperal psychosis in 1911. Has been deaf for many years, left ear more impaired than the right. In October, 1934, she began to notice trouble in writing. Words and letters were well formed, but important words omitted from sentences. In January, 1935, she developed paraphasia characterized by erroneous statements, which the patient herself would correct. About this time trouble was noticed in the movements of the right hand. Coffee was spilled from a cup when the patient tried to drink. The left hand was used for common movements, although the patient was hight-handed and there was no paralysis. It was noticed that the movements of the right hand succeeded better when the patient watched it.

Exploratory operation revealed a large cyst in the left parietal, which was drained and followed by a period of improvement in all symptoms. Air was injected into the cyst cavity, and anteroposterior and lateral x-rays gave a good localization of the lesion, which was about two and one-half inches anteroposterior, two inches vertical, and two inches transverse, extending apparently from the postcentral convolution to the angular gyrus above the fissure of Sylvius.

The patient was able to read and speak, although both these functions were impaired. She understood spoken language, but was somewhat slow in comprehension. Opportunities for study were limited, as the patient was not coöperative, but the data available is sufficient to demonstrate definite apraxia, mainly of the ideokinetic type, due to a lesion of the left parietal lobe.

Although this patient was not studied extensively, she presented a picture of large, well-localized lesion in the left parietal lobe, with symptoms of ideokinetic apraxia in the right hand. There was also a defect of speech and impairment of mental processes.

Case 4.—Miss M. D. Aged twenty-one years. Patient was injured in an automobile accident about seven weeks ago. She had a depressed fracture in the left parietal region, repaired soon after the injury. The patient also had fracture of the right femur near the knee, and numerous minor traumatisms in different parts of the body. She was unconscious for a long time, and there has been gradual recovery; but she has had complete right hemiplegia and complete aphasia since the accident.

Examination: Patient lies quietly in bed, conscious, mentally alert, unable to speak or vocalize or make any vocal sound. Tendon reflexes are hyperactive in the lower extremities, and there is a bilateral Babinski. Abdominals are present bilaterally. She opens the mouth and protrudes the tongue promptly. Has some difficulty in swallowing water (was tube-fed for a time after the accident). Face is expressionless, with very slight movement on the left side, also a very slight raising of the eyebrows. She is able to close both eyes. Has difficulty in showing the teeth, with lagging on the right. Throughout the examination there was no change in facial expression. Patient never smiled, nor scowled nor frowned nor moved the face. Asked if she ever smiled, she moved her lips a little bit, but did not smile. Extra-ocular movements reveal external strabismus of the right eye. Rotation of the eyes to the right fair, to the left not quite so good. Patient is unable to rotate the eyes upward above the horizontal plane. Pupils react to light. Fundi negative. Visual fields not grossly impaired. No hemianopsia. Throughout the examination the patient gave evidence of understanding promptly everything that was said to her. She read different words written on paper, with some mistakes. She carried out a series of consecutive movements with the left hand correctly, although the movements themselves were jerky and poorly coördinated. She moved the left hand and arm freely in all directions, carried out all instructions and orders, but with awkward movements. With the eyes closed she manipulated objects placed in her left hand in a normal manner. The objects were then placed among a number of others in front of her, and on opening her eyes she selected the one that she had been handling.

This case has been included because of symptoms at least simulating apraxia of the sympathetic type; that is, apraxia in the left hand with lesion of the left cerebrum. However, the character of the motor disturbance might be interpreted as being ataxic rather than apractic. It is also evident that, in addition to the cerebral lesion in this case, there are also lesions in the midbrain affecting the ocular movements and possibly also the fibers from the superior cerebellar peduncle.

CONCLUSIONS

Apraxia is a disturbance of motor expression dependent upon disturbance in the association and commissural tracts of the brain and, therefore, less definitely localizable than lesions of the projection tracts. The localizing value of apraxia varies according to the type manifested. Kinetic apraxia indicates lesion involving or in close proximity to the central convolution. Ideokinetic apraxia is caused by lesions outside the motor area, but interfering with its connections with the rest of the brain, especially the parietal temporal lobe. Ideational apraxia is of little localizing value, as it is caused by lesions of the association tracts serving attention, memory, and other psychologic functions. Apraxia is usually accompanied by, although not dependent upon, other disturbances in the association tracts, such as aphasia, agnosia, and mental impairment.

727 West Seventh Street.

DISCUSSION

Walter F. Schaller, M. D. (909 Hyde Street, San Francisco).—Doctor Ingham has presented a very difficult subject concisely and with due emphasis on the original contribution of Liepmann in separating apraxia from allied disorders of brain function. In 1910 I had the opportunity of attending a clinical demonstration by Liepmann in Berlin. His approach was that of mimicry or command in order to demonstrate respectively motor or ideomotor apraxia. The presence of mimia or animia is probably sometimes overlooked through the failure to apply this test for motor apraxia. Not all students of apraxia will agree with Liepmann that motor aphasia is a particular form of apraxia. Henschen, for instance, in his work on aphasia concludes from his analysis of published cases that apraxia and aphemia, or dysarthria, are different disorders.

Apraxia may be so identified with mental deterioration that it is but a symptom of this major disorder, rendering it questionable whether we should call a case such as that described by Doctor Ingham (Case 1) apraxia or dementia with symptoms of apraxia. Case 4 presents the problem of the differential diagnosis of apraxia and ataxia. I should incline to the opinion that this case was rather one of ataxia.

Report of Case.—The following case (G. E.) of ideomotor apraxia is presented with necropsy findings: A male, aged 40, suddenly developed a left-sided hemiplegia and aphasia of predominantly motor type with alexia and agraphia. The heart examination revealed a marked systolic apex murmur. Dementia was not present. Ten days following the onset the following symptoms of apraxia were found: Given a cigarette and match in the right hand, he first put the match in his mouth, then applied the unlighted match to the cigarette. A week later when given an envelope, seal, sealing wax, and a lighted match, he melted the wax, dropped it on the flap of the envelope, but failed to apply the seal. He recovered from the apraxia in approximately two months' time, but the aphasia and the hemiplegia persisted up to the time of his death, from pneumonia, a year and a half after the beginning of his illness: his speech was dysarthric and there were signs of a residual hemiplegia, most marked in the leg. It was assumed, but not definitely stated in the record, that this patient was right-handed. He used his right hand, as in writing, as one naturally right-handed. The necropsy revealed a chronic endocarditis. The brain lesions were limited to the right hemisphere and consisted of three discreet areas of softening. The largest area involved the insular cortex, adjoining frontal operculum and posterior part of the third frontal convolution. Another area was found in the central white matter involving the cortical projection fibers, and also arcuate and callosal fibers. A smaller area was present in the centrum ovale lateral to the anterior horn of the lateral ventricle, and involving the callosal fibers coursing the anterior horn of the ventricle. The hemiplegia was thus explained by the interruption of the motor projection system, the aphasia by the cortical involvement, and the apraxia by the implication of callosal fibers.

*

J. M. Nielsen, M. D. (727 West Seventh Street, Los Angeles).—This is a highly important subject which deserves much more attention than can be given to it here. There is really nothing to be added to the presentation as given by Doctor Ingham.

It might be permissible, however, to mention briefly the localizing value of apraxia. The first type discussed, ideational apraxia, has no localizing value, but, on the other hand, is of great value at times in arriving at the type of toxemia from which the patient is suffering. We see it with relative frequency in bromidism. It also occurs, but less often, in allonal and barbital poisoning. It also results from cortical degeneration in general. Ideo-kinetic apraxia, on the other hand, results from a lesion on the major side of the brain, usually the left, and usually in the parieto-occipital region. Kinetic apraxia of the limbs results from a lesion affecting the motor strip. If this occurs on the major side, there may even be apraxia of the ipsilateral hand while the contralateral one is paralyzed.

Summarized, then, if the patient shows only severe absent-mindedness (ideational apraxia), this is of no localizing value. If he sets out to perform an act, but does something entirely different (such as putting his shoe into his mouth instead of on his foot, or trying to put his arms into the legs of his trousers), he has ideokinetic apraxia, and he suffers with a lesion of the major parieto-occipital region. If he knows perfectly well what he wishes to do and attempts to do it, but does not have individual power of movement of the fingers and must use the hand as a whole, he has kinetic apraxia of the limb, and the lesion affects the motor strip of the contralateral side. If apraxia is properly understood, it adds a great deal to our knowledge of cerebral localization.

*

Thomas G. Inman, M. D. (2000 Van Ness Avenue, San Francisco).—Doctor Ingham has so well described the anatomic and physiologic foundations upon which the theory of the apraxias rests that little remains to be said in discussion.

As an aid in the localization of cerebral disease the discovery of an apraxia may lead to a focal diagnosis, but the plan of examination, as outlined by Doctor Ingham, must be closely followed or confusion will result. Apraxia is a symptom complex existing within a group of other symptoms, and the lesions responsible for it may lie in widely separated areas. An exact diagnosis has led to surgical intervention in the case of tumor, and relief has followed operation. Many of the recorded cases, however, have been of vascular origin and study of them has served the interests of science rather than the needs of the patient.

It was the privilege of this writer to attend Liepmann's course at the Charité in Berlin before the World War. Where the question of apraxia was to be determined, and after the necessary neurological questions had been settled, the master proceeded with the mental examination. Provided with all of the available utensils which the patient would be accustomed to use in daily life, Liepmann would ask their various uses and then direct that they be used in the accustomed manner. One can imagine the puzzled expression on the face of the patient when he found himself unable to execute the desired movements with the apraxic arm.

Well-grounded in philosophy and the sciences, Liepmann brought to the study of cerebral function a mind prepared to analyze the material which came into his hands. His association with Wernicke undoubtedly, through the study of the aphasias, caused him to think of certain results of cerebration as the end-products of a triad of mental (intracerebral) processes; a triad consisting of intrapsychical, psychosensory and psychomotor motivations. Thus his interrogation of a patient followed a prearranged plan intended to show in which of these domains function was disturbed.

Doctor Ingham's studies are of special interest to students of neurology, and lend support to their belief that mind is a product of cellular action and not, as some would have us believe, a mysterious something coming to us from an equally mysterious somewhere.

*

Doctor Ingham (Closing).—The case referred to by Doctor Schaller is of much interest. If the patient was right-handed, as assumed, it is difficult to explain his motor aphasia from a right-sided lesion. Since the apraxia was manifested in movements of the right hand, it should perhaps be classified as sympathetic apraxia, but this would necessitate the assumption that the right hemisphere was the major one. I agree with Doctor Schaller's remarks in regard to the line which must be drawn between mental deterioration and evidences of apraxia. It is a fact, however, that some mental deterioration exists in every case of apraxia. It is only a question of whether the general deterioration is the cause of the disturbed motor functions, or whether the latter are of a specific type of disturbance which we recognize as apraxia. I consider that the motor disturbances were ataxic rather than apraxic in the fourth case, and they were presented to illustrate the problem of a differential diagnosis.

CARDIOVASCULAR SYPHILIS: ITS TREATMENT*

By WILLIAM W. NEWMAN, M.D.
San Francisco

DISCUSSION *by John J. Sampson, M.D., San Francisco; C. W. Barnett, M.D., San Francisco; George V. Kulchar, M.D., San Francisco.*

ONE hears considerable skepticism as to the efficacy of the specific treatment of cardiovascular syphilis. However, almost all statistics dealing with this subject concern themselves solely with the nearly terminal lesions of aneurysm or aortic insufficiency, for the reason that a diagnosis of cardiovascular syphilis can be convincingly established only in their presence. However, it is a fallacy to base our judgment entirely on results obtained after mechanical defects have been produced in valve and aortic wall which must inevitably overwhelm the patient regardless of whether the infection originally producing them is or is not controlled. We should expect our best therapeutic results during the quarter of a century of insidious progress before these irreparable mechanical handicaps occur.

CRITERIA FOR THE DIAGNOSIS OF SYPHILIS

Our criteria for the diagnosis of syphilis in general are:

1. A definite history of infection, or
2. A definitely positive blood Wassermann or Kahn, or
3. A lesion pathognomonic of syphilis, of which only saccular aneurysm or central nervous system syphilis were encountered.

Criteria for the diagnosis of cardiovascular syphilis will be discussed later.

One thousand consecutive patients coming to this office for cardiovascular examination are reviewed. A Wassermann was done on every patient, and except for the first one hundred, also a Kahn. Physical and x-ray examinations were complete in each case. No selection was made of the patients, except in so far as the cost of the examination required a certain financial competence, a factor which doubtless had a bearing on the relatively low incidence of syphilis in our series.

This marked influence of social status on the incidence of syphilis is illustrated by the finding of only 0.2 per cent positive Wassermanns among five thousand University of Minnesota students contrasted to 10.5 per cent[1] among military recruits of about the same age. Similarly, white admissions to Johns Hopkins clinic medical service showed 6.9 per cent positive Wassermanns,[2] while Kisser and Bohner report an incidence in private general practice of only 3.6 per cent,[3] about one-half the clinic rate.

We found 3.4 per cent syphilis among the one thousand consecutive patients, and the Wassermann or Kahn was positive in 3 per cent. In 3.2 per cent, cardiovascular syphilis was diagnosed, and of these, 87½ per cent had positive blood and 12½ per cent negative. The lesions were 22 per cent saccular aneurysm, 34.4 per cent aortic insufficiency, and 43.4 per cent simple aortitis. In the nine hundred cases in which both Wassermann and Kahn were done, there was complete agreement between them in 99.37 per cent. Ages among those with cardiovascular syphilis ranged from twenty-eight to seventy-two years, with an average of forty-eight years, and there were 90 per cent males and 10 per cent females.

TABLE 1.—*Entire Group of One Thousand Patients*

	Cases	Percentage
Incidence of syphilis	34	3.4
Incidence positive blood Wassermann (Kolmer) or Kahn	30	3.0
Incidence cardiovascular syphilis	32	3.2
Complete agreement between Wassermann and Kahn (900 cases)	894	99.37

There were five cases with positive Kahn and negative Wassermann.
There was one case with positive Wassermann and negative Kahn.

IMPORTANCE OF CAREFUL SURVEY OF CARDIOVASCULAR SYSTEM

Since the form of treatment which can be safely given depends on the degree of pathology present, it behooves us to make a careful survey of the cardiovascular system before planning our course of therapy. There is no question as to the importance of the treatment of acute syphilis, and there is general agreement as to what constitutes adequate therapy. In Moore's[4] large series no patient with early syphilis who received as much as three courses of arsphenamin plus interim heavy metal developed clinically recognizable cardiovascular syphilis.

LATENT SYPHILIS

This leads directly to the question of what attitude, from the cardiologist's point of view, should be taken toward the treatment of so-called latency. We must bear in mind that the patient who comes to us with an aneurysm or syphilitic aortic insufficiency may have passed through a period of over twenty years of what we designate as latency. Should we then contemplate withholding treatment from the next syphilitic who consults us merely because he has not yet developed these lesions? The answer depends, of course, on what we know concerning the course of latent syphilis in the treated and untreated patient. Even if we accept Brunsgaard's optimistic figures on the outcome of untreated syphilis, we find that about 25 per cent will die as a direct result of their syphilis, most of them (one in seven of those originally infected) from cardiovascular syphilis.[1 p. 237] On the other hand, according to Moore, treatment of latent syphilis diminishes the probability of progression, relapse, or death, from this 25 per cent to about 5 per cent. These excellent results should not, strictly speaking, be considered merely as evidence of the *prevention* of cardiovascular syphilis, but rather of the arrest of the subclinical disease; for we know from the pathologic studies of Warthin,[5] Langer,[6] etc., that 70 to 90 per cent of these patients with so-called latency would show at least microscopic pathologic evidence of syphilis of the aorta, and from clinical studies that 10 to 15 per cent of them, if untreated, will die from cardiovascular syphilis. In the face of such figures it would seem that there should be no hesitancy in concluding that latent syphilis should be treated, except perhaps in the patient over fifty years of age without symptom or sign except the positive blood. Doctor Goecherman, in this symposium, has fully covered the details of therapy of latent syphilis.

---

* Read before the Dermatology and Syphilology Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

The next group of patients are those whose cardiovascular pathology has progressed far enough to produce signs and symptoms of cardiovascular disease, but has not yet destroyed aortic cusps or caused aortic aneurysm. It is, we believe, at this stage where it appears that the syphilitic has definitely embarked on the course of active cardiovascular involvement, but where the myocardium is not yet exhausted attempting to cope with the handicap of an aortic regurgitation, nor the aorta already stretched to the bursting point, that the greatest benefit, relatively speaking, can be accomplished with specific treatment.

DIAGNOSIS OF CARDIOVASCULAR SYPHILIS

We must admit at the outset that this statement does not lend itself to statistical proof, since the clinical diagnosis of cardiovascular syphilis prior to the appearance of aortic insufficiency or aneurysm cannot, we think, be made with enough certainty to make comparative figures based thereon valid. This does not mean that the diagnosis as a guide to treatment cannot be arrived at with reasonable certainty, though often it must be made by exclusion, inference, and suspicion. Unfortunately there is no pathognomonic sign for early or subclinical cardiovascular syphilis, as there is in the spinal fluid examination for subclinical central nervous system lues.

Table 2.—*Analysis of the Thirty-two Patients With Cardiovascular Syphilis*

	Cases	Percentage
Males	29	90.6
Females	3	9.4
Incidence of positive Wassermann or Kahn	28	87.5
Incidence of negative Wassermann or Kahn	4	12.5
Saccular aneurysm	7	22.0
Aortic insufficiency	11	34.4
Simple aortitis	14	43.6

In arriving at a presumptive diagnosis of simple syphilitic aortitis, we must of course in the first place be reasonably certain that the patient has syphilis, and for this we must depend by far most importantly on the presence of a positive blood test. Except in the presence of aneurysm it is a bold physician who will make the diagnosis of cardiovascular syphilis in the face of a negative Wassermann, even when pathology is advanced. The truth of this statement is shown by the low incidence of negative Wassermanns, 2 to 5 per cent,[1] in clinical series, compared with the relatively high incidence of negative serology, 25 to 30 per cent,[7,8,9] when the diagnosis is made at postmortem. Such figures, of course, mean, not that the blood is practically always positive in cardiovascular syphilis, but rather that the diagnosis is most rarely made clinically unless the blood is positive.

Having satisfied ourselves that the patient has syphilis, we must next decide whether he has heart disease, and lastly whether that heart disease is of a sort likely to have been caused by syphilis. Symptoms usually antedate signs, yet those of cardiovascular syphilis differ little from those of other types of heart disease, especially the hypertensive form, except that possibly vague or more severe substernal pain brought on or increased by exertion plays a rather more prominent rôle than do dyspnea or swelling of the ankles.

PHYSICAL EXAMINATION

Physical examination at this stage consists in an attempt to detect an abnormal aorta. We are unable to recognize the Tambour second aortic sound, so often mentioned as characteristic of syphilitic aortitis,[10] nor can we percuss satisfactorily increased retromanubrial dullness. A faint pulsation, best felt on deep pressure at the end of expiration in the second intercostal space to the right of the sternum, means a dilated aorta, and a systolic murmur over that same area should not be dismissed as of no consequence.

ROENTGEN-RAY EXAMINATION

It is, however, from a combination of x-ray and fluoroscopic examination that we obtain our earliest information of aortic disease. The routine anteroposterior and true lateral chest plates often miss the beginning dilatation, which usually pushes out from the aortic root forward toward the sternum and slightly to the right, so that its contour is thrown best into profile in the left anterior oblique position, that is, with the patient rotated so that the front of his left shoulder touches the plate, the optimum degree of rotation being found by fluoroscopy in each individual case. Obtaining a picture of such a dilatation is much facilitated by doing the fluoroscopy at six feet, finding the best angle of rotation under the fluoroscopic screen and then not moving the patient at all, but dropping the casette between screen and patient and flashing a plate of the image just observed. Figure 1 shows an arrangement for doing this. Pictures of small localized dilatations along the course of the

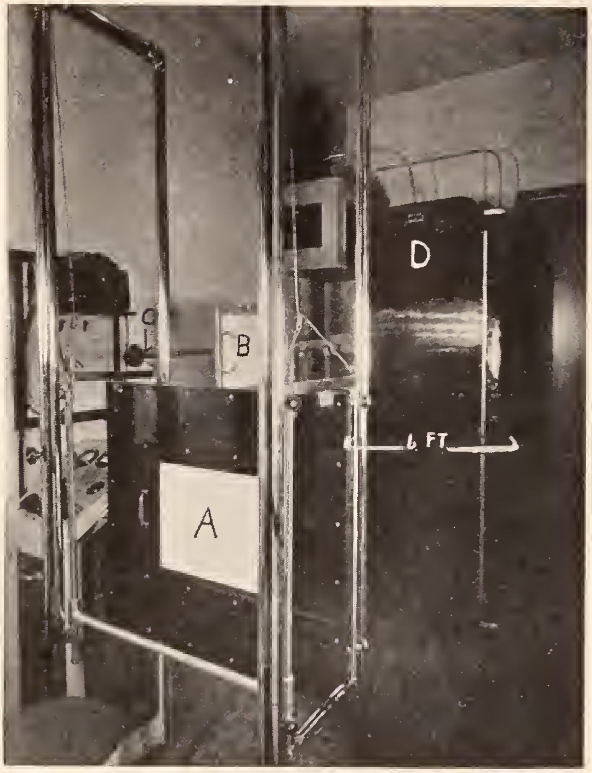

Fig. 1.—Arrangement for fluoroscopy at six feet: A, Adjustable fluoroscopic screen mounted six feet from tube and arranged to hold a cassette at its back; B, Conventional fluoroscopic screen swung out of way; C, Extension to shutter control arm; D, Back rest of conventional vertical fluoroscope.

aorta can be obtained by this method which easily might otherwise be missed.

While the electrocardiogram gives no information specifically characteristic of syphilitic cardiovascular disease, it is of value in judging the state of the myocardium which may be damaged before the development of aortic insufficiency. Usually when electrocardiographic changes are present, symptoms of pain or breathlessness on effort are also in evidence.

So then, having a patient with a positive Wassermann, especially if he is under fifty years of age and complains of substernal pain or dyspnea on exertion, in whom x-ray shows an aortic shadow more dense or broad than one would expect for the patient's age, or blood pressure, or who has a localized dilatation of the ascending aorta, often best seen in the left anterior oblique position, we feel that a presumptive diagnosis of active cardiovascular syphilis is justifiable and specific therapy is urgently indicated, as it is at this point of simple aortitis that the last good chance of a symptomatic cure is possible before valve leak or aneurysm do irreparable damage. Treatment must now be somewhat more cautiously initiated than before the onset of symptoms and signs has occurred, and should not commence with arsenic. At least eight weekly injections of bismuth, plus potassium iodid by mouth, should precede the neo, the first dose of which should not exceed 0.3 gram and the succeeding weekly doses of the course of eight not over 0.6 gram, after which the bismuth course is repeated, so that in the first eighteen months three such courses of bismuth and of neo are planned. Thereafter one yearly course of each is advisable as a routine, irrespective of the serologic status. Treatment during the stage of simple aortitis not infrequently requires the application of such nonspecific measures as rest, digitalis, diuretics, etc.

DIAGNOSIS OF THE TERMINAL LESIONS

Diagnosis of the terminal lesions of syphilitic cardiovascular disease, aortic insufficiency, and aneurysm, rests on the points enumerated above for uncomplicated aortitis, but here is aided and simplified by the presence of the physical signs of an aortic valve leak, or x-ray evidence of aortic aneurysm. In the latter case the lesion is in itself practically pathognomonic and requires no supporting data, not even of syphilis.

TREATMENT

Even though, as C. W. Barnett states,[11] "the beneficial effect of specific treatment on the prognosis of syphilitic aortic insufficiency remains unproved," still much suggestive evidence of its value even in this late stage has been adduced by Moore,[1] Stokes,[10] Reid,[9] Grant,[12] etc., Grant followed for ten years 189 patients with syphilitic aortic insufficiency and aneurysm, one group of whom were given specific treatment and another strictly comparable group were kept as controls. The proportion of his patients in each group, dead, or living and unchanged at the end of ten years, certainly seems to favor the results of specific therapy (Table 3).

The arsenicals, in the face of aortic insufficiency or aneurysm, should be used most cautiously; the initial dose of neo should be reduced to .1 gram and the succeeding doses to not over .3 gram, and this should always be preceded by ten to twelve weekly injections of .1 to .2 gram of bismuth and by potassium iodid. If there are no untoward results, about three such courses of neo and bismuth may be given in the first eighteen months, but no rigid schedule can be followed.

In the face of frank decompensation with swollen legs, orthopnea, and hydrothorax, or in patients who have frequent, severe, and easily provoked anginal attacks, the first thought is not of specific, but rather nonspecific measures, of which

Table 3.—*Effect of Specific Treatment on Syphilitic Aortic Insufficiency and Aneurysm Over a Period of Observation of Ten Years. (Modified, from Grant.)*

GROUP 1 No Specific Therapy		GROUP 2 Treated with Arsenic, Mercury, and K1	
Number of cases	46	Number of cases	52
Cases living uneventfully and unchanged	7 (15%)	Cases living uneventfully and unchanged	12 (23%)
Deaths	31 (67%)	Deaths	25 (48%)

bed rest is preëminent. In edematous patients intravenous salyrgan is particularly apropos, being both a diuretic and a mercurial. Unless the patient reaches a stage of compensation through these means, allowing him to be up and about at least a few hours a day without gross edema, severe dyspnea, or frequent and severe anginal attacks, we feel that the arsenicals are contraindicated. However, the heavy metals and iodids can always be started as soon as full digitalization, the tapping of effusions, the administration of oxygen, etc., have alleviated the pressing symptoms of decompensation.

SUMMARY

1. The incidence of syphilis in one thousand consecutive ambulatory patients seen in the private practice of cardiology was 3.4 per cent, and of cardiovascular syphilis 3.2 per cent.

2. Of these 43.6 per cent had simple aortitis, 34.4 per cent aortic insufficiency, and 22 per cent aneurysm.

3. The blood Wassermann or Kahn was positive in 87.5 per cent and negative in 12.5 per cent.

4. For practical purposes a diagnosis of cardiovascular syphilis is justifiable in any patient with a saccular aortic aneurysm; or in any patient over forty years of age with aortic insufficiency and a positive Wassermann, provided there is no stenosis of any valve nor definite history of rheumatic fever;[8] or in any patient with a positive Wassermann or Kahn, especially if he is under fifty years of age and complains of substernal pain or dyspnea on exertion, in whom x-ray shows an aortic shadow wider than one would expect for his age, or blood pressure, or who has a localized dilatation of the ascending aorta, often best seen fluoroscopically in the left anterior oblique position.

5. Adequate treatment of early syphilis is extremely effective in the prevention of clinical cardiovascular syphilis.

6. In the presence of established cardiovascular syphilis the preponderance of evidence (although not strictly applicable to statistical analysis) is in favor of the beneficial effect of specific therapy, not only with the heavy metals and iodid, but also with arsenicals in suitable dosage.

7. The earlier in the course of the disease specific therapy is begun, particularly before the onset of aneurysm or aortic insufficiency, the better are the chances of improvement.

DISCUSSION

John J. Sampson, M. D. (490 Post Street, San Francisco).—The difficulties of diagnosing early cardiovascular syphilitic lesions, especially in patients with negative serologic tests, and the effect of adequate treatment in preventing cardiovascular syphilis, have been indicated by Doctor Newman.

One of the most serious diagnostic problems is the patient with arteriosclerotic or rheumatic heart disease and a positive blood Wassermann reaction. In my belief these cases should be treated just as are those of well-established syphilitic heart disease. Just what method of treatment should be used in clearly diagnosed syphilitic aortic insufficiency, or aortitis, is a problem in constant dispute. From personal experience, and that of the workers quoted by Doctor Newman, a more optimistic attitude toward results of active treatment may be assumed. At least a prolongation of life seems to be established by statistical studies. Naturally patients with large obstructing aneurysms, or in marked congestive heart failure, are not given arsenical treatment; but I believe that aortic dilatation or aortic valve insufficiency in themselves are not contraindications. An apparently good rule is to attempt to save any cardiovascular system that is maintaining the patient in social usefulness.

The elements of danger in adequate arsenical treatment of cardiacs may be enumerated as: (1) serious nitrotoid reactions; (2) pulmonary edema; (3) Herxheimer reactions; and (4) the dissolution of an aneurysm wall with rupture. The first element, nitrotoid reaction, may generally be prevented by initiating arsenical treatment with small doses, as suggested by Doctor Newman; the second, pulmonary edema, is an uncommon complication of any type of intravenous therapy, and has been observed twice in my personal experience during arsphenamin administration; the third, the Herxheimer reaction, is another rarity, and personally observed only once, and that in a case following preliminary mercury and iodid therapy as generally advised and outlined in Doctor Newman's paper; the fourth, aneurysm rupture, is the most commonly feared complication, but the one which is unsubstantiated by practically any pathologic proof.

It is well recognized that untreated syphilitic cardiovascular disease may advance very slowly, but certainly this is not a general observation. Thus, with little danger in active treatment and the suggestive evidence that arsenical therapy holds the disease stationary, we have good reason for using it even in reasonably advanced cases. The prevention of advancing destruction of the myocardium seems to me a logical explanation of the apparent benefits.

At the cardiovascular clinic of the University of California, we have encountered a mortality of 25 per cent in eighty-seven cases, over a thirteen-year period. We have observed in this group cases of aortic insufficiency which have been clinically stationary or improved during five to twelve years of active treatment, including twenty-five to eighty doses of neosalvarsan in addition to bismuth, potassium iodid, and mercury. No fatal nitrotoid reactions or ruptured aneurysm following arsenical injections were observed in the entire period. We have seen, likewise, cases progress to rapidly fatal terminations during persistent treatment. In spite of this I feel that the disease has often been held in check.

* * *

C. W. Barnett, M. D. (Stanford University Hospital, San Francisco).—Autopsy reports show evidence of aortitis in a large percentage of patients with supposedly latent syphilis, but only a few of these patients ever develop serious disability. The problem in simple aortitis is, therefore, not to make a diagnosis of a condition which is present in nearly every patient with syphilis, but to pick out from the whole group those in whom the process is likely to advance. The signs and symptoms mentioned by Doctor Newman are undoubtedly useful for this purpose. There is, however, a good deal of uncertainty as to the prognosis, and because of this the beneficial effects of treatment have not been proved.

When aortic regurgitation of aneurysm complicates the picture, the diagnosis is more certain and the prognosis is better known; but the effects of treatment are still doubtful. The results of treatment as shown by Grant are given in this paper. These figures are apparently more accurate than any others that have been published up to the present time. They suggest that specific therapy does improve the prognosis slightly in these more advanced stages of the disease.

* * *

George V. Kulchar, M. D. (450 Sutter Street, San Francisco).—At the present time the value of specific treatment in cardiovascular syphilis is debatable. The apparently satisfactory results cited by Moore and his coworkers as evidence of the value of specific treatment is open to the criticism of analysis by the retrospective method. That is to say, patients who lived the longest following the beginning of treatment naturally received the greatest amount of therapy and fell into the "satisfactory outcome group." On the other hand, the patients who died within a few weeks following the beginning of treatment were placed in the "unsatisfactory outcome group." This method of analysis gives rise to a considerable error. As pointed out by Barnett, the only method by which the effect of treatment can be definitely evaluated is by careful observation of a large number of patients until death, half the series receiving specific treatment, and the other half no specific treatment. Every alternate patient, regardless of the stage or severity of the disease, should be used as a control. It is only through a survey by this method, made over a period of years, that the actual value of specific treatment in cardiovascular syphilis can be determined. Regardless of the effect of treatment on the ultimate outcome in cardiovascular syphilis, the symptomatic relief obtained is often striking. I agree with Doctor Newman that treatment should not be started in the presence of frank cardiac decompensation; rather all efforts should be directed toward restoring compensation. Digitalis, except when auricular fibrillation is present, is of little value. Preliminary preparation with mercury succinimid in one-sixth grain doses, given intramuscularly three times a week along with potassium iodid by mouth, is most important in the treatment of cardiovascular syphilis. After four to six weeks of such preparatory treatment, the arsphenamins may be used, as suggested by Doctor Newman. Except in early aortitis, neoarsphenamin is preferred to aresphenamin. Another drug which has a definite place in the treatment of aortic insufficiency and aneurysm is bismarsen (bismuth arsphenamin sulphonate). Many syphilologists, including Stokes, maintain that it is the drug of choice. The low toxicity, the therapeutic efficiency, and marked tonic effects make bismarsen particularly adaptable to the treatment of cardiovascular syphilis. It is well tolerated, even by the most debabilitated cardiac. It should be given in an unbroken series of from forty to eighty intramuscular injections at five- to seven-day intervals. Bismarsen deserves wider popularization in the treatment of cardiovascular syphilis.

BILATERAL DISLOCATIONS OF THE CERVICAL SPINE*

By Ralph Soto-Hall, M.D.
and
Keene O. Haldeman, M.D.
San Francisco

Discussion *by Don King, M.D., San Francisco; Rodney F. Atsatt, M.D., San Francisco; Howard W. Fleming, M.D., San Francisco.*

It is our purpose to review the subject of bilateral or complete dislocations of the cervical spine, leaving aside any discussion of the so-called unilateral cases. Many of the large series of cases of cervical injury reported in the literature are composed chiefly of unilateral dislocations, in which treatment is simpler and the results much better. The reduction and postoperative care of these unilateral cases is a problem of an entirely different nature. In the bilateral dislocations serious injury to nerves, vertebrae and intervertebral discs, and recurrences and residual mechanical arthritis, are common.

In order to obtain a true cross-section and clear understanding of these problems, we have reviewed a series consisting of forty cases from our private practice and from clinics served by us, and have included eight cases from the files of the Industrial Accident Commission. The latter are particularly valuable in that they show end-results with the percentage of permanent disability and the corresponding monetary loss.

REVIEW

One of the early advances in the reduction of these injuries was the method of manipulation devised by Walton.[1] This is chiefly applicable to the unilateral dislocations, and is carried out by bending the head backward and to the side away from the lesion, thus increasing the deformity. The next maneuver consists of a rotation of the head toward the side of the lesion, which permits the dislocated facet to drop into place.

In the bilateral, forward, dislocations, the foregoing method has been largely replaced by that of Taylor [2] in which reduction is accomplished by traction, hyperextension and gentle manipulation, followed by immobilization of the neck in plaster. This treatment will be described later in detail. Fleming [6] has made use of lumbar puncture and manometric estimations, in association with the Taylor manipulation of cervical dislocations to determine the disappearance of subarachnoid block. Such a disappearance of block was thought to indicate a reduction of the dislocation. The symptoms of severe injury to the spinal cord, often associated with cervical dislocation, have inclined some surgeons to advocate *early* laminectomies in the hope of relieving pressure on the cord. This treatment received experimental support in the work of Allen,[3] who did laminectomies

in dogs following the production of injuries to the cord, and observed better recoveries in the dogs in which the dura had been opened, as compared with nonoperated controls. Coleman[4] used the Queckenstedt test for subarachnoid block (spinal puncture and jugular compression) to determine the advisability of early laminectomy. The disastrous experiences of Taylor and other surgeons who opened the dura following cervical dislocations, has caused a trend toward conservative treatment. Towne,[5] in a recent review, concluded that "laminectomy can do no good in cases of injury of the spinal cord resulting from dislocation of the spine, and may do harm."

In the past five years several large series of cases of cervical dislocation have been reported. Langworthy[7] cited thirty personal cases, of which seventeen were bilateral dislocations. Of the latter patients, five died and one of the surviving patients had a recurrence of the dislocation. A comprehensive analysis of forty-eight patients having various types of injury of the cervical spine was presented by Mackh[8] from the Harbor Hospital in Hamburg. He found the mortality rate to be 5 per cent in patients with partial dislocation, and 30 per cent in those with total dislocations. Brookes,[9] in 1933, reported forty cases of cervical dislocation, of which number, eleven were bilateral dislocations. Complete reduction was obtained in twenty-eight, partial reduction in eight, and failure resulted in one case. No attempt was made to reduce the dislocation in three patients. Redislocation occurred in four patients (10 per cent). The same author[10] brought his series of traumatic dislocations of the neck up to sixty-five in 1935.

From an inspection of the illustrations in the papers mentioned in the preceding paragraphs, it is apparent that many cases which were considered reduced actually showed the persistence of a slight forward displacement of the vertebra. This incompleteness of reduction predisposes to a recurrence of the dislocation, or at least leads to persistent symptoms of damage to the nerve roots, and arthritic changes. We must raise our standards of satisfactory reduction, and must insist upon a perfect realignment of the anterior borders of the vertebrae.

ANALYSIS OF FORTY CASES OF BILATERAL DISLOCATION OF CERVICAL SPINE

In this series of forty cases males constituted 82 per cent of the patients (Table 1), an incidence which is characteristic of injuries occurring largely in industry and sports. The decades from thirty to forty, and from forty to fifty, contained the largest number of cases, the average age being thirty-five years (Table 2).

While a large variety of causes of dislocation were found, automobile accidents were in preponderance (Table 3). Diving into shallow water accounted for four such injuries, and falls for most of the remainder. The most vulnerable vertebra (Table 4) appeared to be the fifth cervical, followed in order by the sixth, fourth, and first cervical vertebrae. The latter localization occurred in the younger patients (average age twenty-five years). Fractures of the vertebral body or some portion of the neural arch were associated with the dislocation in one-half of the series. This incidence is probably larger because minor fractures are often overlooked.

The symptoms and signs associated with dislocations of the neck may be grouped as local signs (torticollis, limitation of motion, pain in

the neck), symptoms of injury to nerve roots (paresthesias and anesthesias over shoulders and arms), and those of injury to the spinal cord. Symptoms of the latter were noted in twenty-five patients, consisting, in the order listed, of paralysis of the arms, anesthesia and paralysis of the legs.

No specific treatment was characteristic of this series. Usually a manipulative reduction was carried out, followed by the application of a cast including the body and neck. Open reduction or laminectomy was performed on seven patients for correction of deformity or relief of pressure on the spinal cord.

In such a study as this, the results are difficult to interpret, owing to the incomplete follow-up notes in some of the clinic cases. The private cases showed, in most instances, a complete recovery within from six to eight months after the injury. Results in clinic cases were often less gratifying because recurrence was more common and there was a less rigid supervision of their after-care. As a rule, there was gradual disappearance of symptoms of injury to the spinal cord, although some weakness, anesthesia or paresthesia often persisted indefinitely. Pain arising in the nerve roots was particularly annoying in certain patients who had not received early and adequate treatment.

A recurrence of the dislocation following reduction was noted in four patients. Death within a few days of the accident occurred in seven instances. Of special interest is the expression of end-results as observed in the record of eight patients with cervical dislocation who received permanent disability ratings by the Industrial Accident Commission of California in the years 1926-1934 (Table 5). The average permanent disability rating was 51 per cent, with an average cash payment of $3,865. These figures emphasize the tremendous physical and financial loss which results from such injuries, many of which did not receive an early diagnosis and few of which were given adequate treatment. Indeed. the medical records in almost all of these eight cases indicated an incomplete reduction or a recurrence of the dislocation.

TREATMENT

It need hardly be emphasized that the foremost consideration in the care of patients with fracture-dislocation of the cervical spine is the immediate reduction of the dislocation. With proper care in handling, such a reduction can be carried out without anesthesia and without jeopardizing the life of the patient. Early diagnosis and prompt treatment will greatly lessen the duration and extent of disability, since the edema and compression of the spinal cord caused by the displacement of the vertebra are the chief complications of such injuries.

We believe that the Taylor method of manipulation, followed by the type of immobilization to be described, offers the most satisfactory solution of this problem. The patient is placed on his back on any type of rigid table, and a head sling of muslin is so arranged that one loop rests upon the patient's chin and the other loop beneath his occiput. The ends of the sling are passed around the waist of the surgeon and tied. This permits the latter to maintain constant traction on the head by resting his weight against the sling, and at the same time leaves both his hands free to carry out gentle manipulation of the patient's neck (Figure 1). A steady downward pull on each of the patient's arms, by assistants, provides the necessary countertraction. Traction on the head is maintained for at least fifteen minutes to permit relaxation of the cervical muscles. The dislocated facets can often be felt to slip into place, and the patient may note immediate relief. The manipulation consists of a gradual increase in extension of the neck combined (in patients having torticollis) with Walton's maneuver of lateral flexion to increase the deformity, followed by rotation away from the deformity. When a satisfactory reduction seems to have been accomplished, this

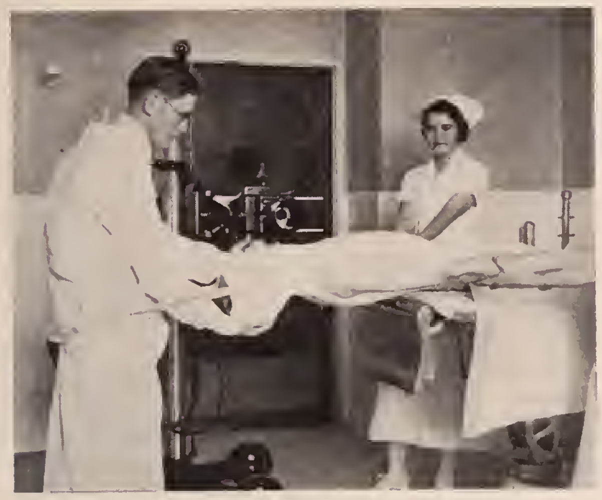

Fig. 1.—Taylor method of reduction of cervical dislocation. Note the portable x-ray unit.

position should be checked by a fluoroscopic examination or a film taken with a portable x-ray unit. After reduction has been proved, a cast is applied which includes the chin and occiput, and extends down to the iliac crests, with the neck in complete hyperextension. Because of the high incidence of recurrence, even with a cast such as this, we have recently incorporated two small turnbuckles in the cast, extending from the region of the middle of each clavicle to the side of the chin. The oblique position of the two turnbuckles prevents lateral motion of that portion of the cast which supports the chin (Figure 2). If subsequent x-ray films, which are taken at intervals of two or three days, show any slipping forward of the injured vertebra, the cast is cut in a transverse direction anteriorly to include two-thirds of the circumference of the neck, and increased extension of the neck is obtained by means of the turnbuckles. Thus recurrent dislocation is reduced or prevented."

The first cast is worn for from eight to twelve weeks and is followed by a Thomas collar for about four weeks longer, the length of immobilization depending upon the severity of injury and upon the evidence of repair given by the x-ray. After two or three months the latter often shows a solid bridge of bone extending from the anterior border of one vertebra to another at the site of dislocation.

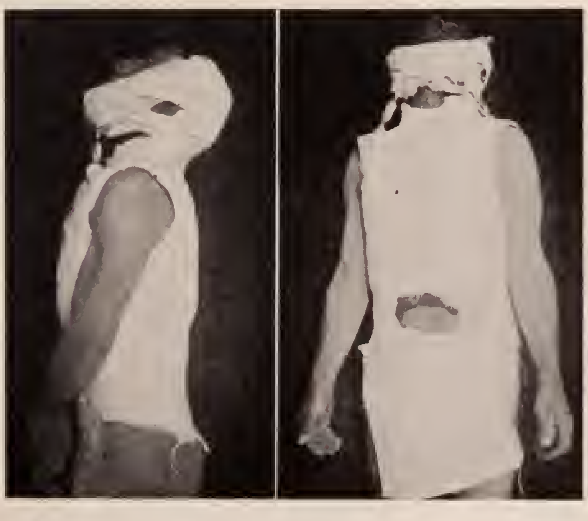

Fig. 2.—Lateral and anterior views of cast, with turnbuckles to provide adaptable hyperextension of the neck.

REPORT OF CASES

A few cases treated by various methods have been selected for special study because they illustrate the problems presented by these injuries and point the way to a rational method of treatment.

* * *

Case 1.—J. M., male, fifty years of age, had his chin caught beneath the wheel of an overturned automobile. There was immediate and complete paralysis and anesthesia from the shoulders down. Lumbar puncture showed a blood-tinged spinal fluid and an incomplete block. An attempt was made to reduce the complete dislocation of the sixth cervical vertebra, with partial success, but with no improvement of neurologic signs. The patient expired three days after the injury. It is evident that the spinal cord was completely severed by the injury, and that any treatment was hopeless.

* * *

Case 2.—J. D., male, fifty years of age, was thrown on his neck when an automobile overturned. He had immediate pain in the back of the neck, and numbness and tingling of both arms, indicating pressure on the nerve roots. An x-ray examination showed a dislocation of the fifth cervical vertebra and a fracture through the laminae of the neural arch. The dislocation of the fifth cervical vertebra was reduced by traction on the head under the fluoroscope, with immediate relief of pain in the arms, and a cast was applied. A few days later the pain in the arms recurred, and a lateral radiogram showed that the fifth cervical vertebra had again slipped forward. Later attempts to reduce this recurrence were only partially successful.

This case demonstrates the necessity for immobilization of the neck in complete hyperextension, which had not been done. The associated fracture of the neural arch also favored a recurrence of the dislocation.

* * *

Case 3.—F. R., male, thirty-five years of age, injured his neck in an automobile accident. He complained only of pain in the neck, and a neurologic examination was negative. Two days later the x-ray revealed a dislocation of the fourth cervical vertebra. This was reduced by traction on the head for twenty minutes, followed by the application of a cast. Two weeks later another radiogram revealed the recurrence of the dislocation. An open reduction was carried out, and the fourth cervical spinous process was wired to that of the sixth cervical in the hope of preventing another recurrence. Films taken two months later showed a definite increase in the displacement of the fourth cervical vertebra.

This case also illustrates the need for hyperextension after reduction and shows the futility of an attempt to prevent displacement of an imperfectly reduced vertebra by means of internal fixation.

* * *

Case 4.—E. A., male, seventeen years of age, dived into shallow water. He had a complete quadriplegia which cleared up following manipulation under anesthesia. The reduction was followed by a cast to the chest and neck for seven weeks, after which a very ineffective metal collar was worn. The weakness of all four extremities gradually increased, and at the time of examination by Dr. Howard Fleming and one of the authors, fourteen weeks after the injury, there was almost complete quadriplegia. Radiograms showed a severe compression fracture of the fourth cervical vertebra, with dislocation of the third cervical vertebra, producing a sharp backward angulation of the spine at that level. A laminectomy was performed, and the spinal cord, which was compressed against the body of the fourth cervical vertebra, began to pulsate when the laminae were removed. After the laminae had been removed, it was impossible to obtain any correction of the deformity, even with strong traction on calipers fixed in the mastoid region. The patient began to improve immediately after the operation, and showed a progressive return of strength to all extremities over a period of two years.

Recurrence because of inadequate immobilization is again shown, and the value of *late* laminectomy to relieve pressure on the spinal cord is demonstrated.

* * *

Case 5.—H. de M., female, thirty-five years of age, was injured in an automobile accident. She presented a flaccid paralysis and anesthesia of the right arm. A dislocation of the fourth cervical vertebra was completely reduced by steady traction for twenty minutes, followed by hyperextension of the neck. The hyperextended position was maintained by a cast extending from the iliac crests to the head. Immediately after reduction, power returned to the right arm, and the sensory disturbance gradually disappeared. The patient made a complete recovery.

* * *

Case 6.—B. F., thirty-seven years of age, was injured in an automobile accident. In addition to an injury to the neck, she sustained a dislocation of the hip which was reduced at once. No radiograms of the neck were made until six weeks after the accident, when they showed a dislocation of the fifth cervical vertebra. She presented a marked limitation of the movement of the neck and pain over the distribution of the cervical nerves. Reduction of the dislocation was accomplished by gradual hyperextension of the neck as the patient lay on a Bradford frame, and traction for twenty-four hours was maintained with a head halter. The neck was then immobilized in a long cast, in which a turnbuckle was incorporated to permit a gradual increase in the degree of hyperextension, in the manner previously described. The patient made a complete recovery within three months of the institution of treatment.

* * *

Case 7.—R. T., male, three and one-half years of age, fell out of a tree. His mother observed a marked torticollis and forward inclination of the neck, but was sure no serious injury had occurred because the boy's appetite was unimpaired. One week later, however, an x-ray examination showed a dislocation of the second cervical vertebra. The neck was quite rigidly held in forward flexion, but a neurologic examination was negative. The Taylor type of manipulation under anesthesia gave a complete reduction of the dislocation. Immobilization of the neck in hyperextension was maintained with a long cast to which two turnbuckles were attached. No signs of injury were present four months later.

* * *

Case 8.—S. S., male, forty-five years of age, was thrown from a mowing machine. He experienced pain in the neck and right arm, and weakness of both arms. These symptoms persisted without treatment until our examination four weeks later, which showed a dislocation of the fifth cervical vertebra and a fracture of its spinous process. Treatment at the time consisted of continuous traction for one day followed by manipulation of the neck without anesthesia. The dislocation was reduced, after which a cast was applied from the iliac crests to the head. A few days later the x-ray showed a partial recurrence of the dislocation, which was corrected by cutting the cast anteriorly at the level of the fracture, attaching two turnbuckles to the cast from shoulder to chin and gradually increasing the extension of the neck until full hyperextension was attained. This immobilization was continued for three months, after which a metal collar was worn for one month. A radiogram then showed a firm bridge of bone connecting the anterior surfaces of the fifth and sixth cervical vertebrae. Six months after the beginning of treatment, the neck had a normal range of motion, although the patient still complained of occasional slight pain in the neck, which was probably the result of arthritic changes.

CONCLUSIONS

1. Dislocations of the cervical spine, with or without associated fractures, demand immediate reduction and prolonged immobilization of the neck in hyperextension.

2. Failure of early diagnosis and adequate treatment results in permanent disability, because of arthritic changes in the spine and compression of the nerve roots or spinal cord.

3. A method of postmanipulative immobilization is described, which consists of the attachment of small turnbuckles to a long plaster jacket and collar in such a way as to permit a gradual increase in the hyperextension of the neck.

4. A series of forty cases of bilateral dislocation of the cervical spine is analyzed with regard to incidence, localization, causation, treatment, and final results.

DISCUSSION

Don King, M.D. (Stanford University School of Medicine, San Francisco).—In cervical spine dislocations, accurate anatomic reduction and prolonged retention are essential for proper function, comfort, and stability. Since Taylor first described his manipulative technique, there has been a gradual acceptance of the fact that reduction can be safely and efficiently accomplished by manipulation. The discomforts and difficulties of traction in the overcorrected position have led to a more general use of the plaster cast to maintain reduction and hasten ambulation. As the authors have pointed out, recurrence of the dislocation, in spite of the plaster cast, is prone to take place. Anyone who has had the disconcerting experience of a recurrence will welcome the authors' suggestion of using turnbuckles in the cast to maintain and increase the hyperextended position of the cervical spine.

⁂

Rodney F. Atsatt, M. D. (1421 State Street, Santa Barbara).—Doctors Soto-Hall and Haldeman are to be commended for bringing up this timely subject. It is often a serious question deciding what to do at the critical time in order to conserve bone structures, nerve structures, or life itself. The clear review of methods of handling these difficult injuries is very valuable.

May I emphasize several points which have already been made but which, to my mind, are important in treatment?

The first is early and accurate diagnosis; this is often hard to achieve because of the difficulties of x-ray technique, especially in the lower cervical region.

The second point is gentleness in manipulation. If the laminae are intact the dislocation must be reduced, but certainly not by "unskilled labor," as life often hangs by a precarious thread during these moments.

The third point is the authors' very ingenious device for maintaining hyperextension, by use of turnbuckles; an old principle, with a new application. This should give excellent results.

In listening to their paper, however, I miss the mention of traction in the treatment of certain types of fracture dislocations. Traction in hyperextension with the old Sayre sling halter or one of the newer modifications is a method which must never be forgotten.

There is another thing which I would like to bring to your attention: occasionally we see a case where ultraconservatism seems to be indicated. As an example of this type of injury, I would like to present one case.

Male, aet. 55, CWA employee. While working on a steep bank, a root upon which he was pulling gave way, allowing him to roll and fall about 25 feet. He sustained a forward dislocation of the second cervical vertebra on the third, a transverse fracture of both laminae in the mid-portion, and a chip fracture of the anterior edge of the body of the third. There was only local pain—absolutely no cord symptoms. Manipulation might have been productive of a reduction, depending upon whether or not the anterior ligaments were intact. However, I felt that while the persistence of the dislocation of the body would give some residual stiffness, the natural laminectomy which had been performed had better be left alone, and this was done. Head traction, eight weeks' metal collar and adequate intensive physical therapy for four weeks, back to light work in three months, and full work as laborer in four and one-half months with very little loss of mobility in the neck.

This case also brings up the question of physical therapy. It seems to me there is no step in the care of these cases of more importance than that given by an adequately trained physical therapist, one who knows and understands muscle reëducation. I am sure that the authors will agree that such rehabilitation is of utmost importance in cases involving joints, muscles, and ligaments.

⁂

Howard W. Fleming, M. D. (384 Post Street, San Francisco).—The paper by Doctors Soto-Hall and Haldeman gives emphasis as to the necessity of early reduction and proper support in cases of cervical spine dislocation.

The complication in such cases that gives most concern is the damage to, or continued pressure on the spinal cord. We have found it advantageous to combine the Queckenstedt test with the Taylor manipulation. Our primary object is not to use the test to determine anatomical reduction of the dislocation, as is suggested in the text of this paper under discussion. Frequently, it is possible to predict satisfactory reduction by what one hears and feels in the patient's neck, and also by the reappearance of normal reactions to jugular compression. However, satisfactory anteroposterior and lateral x-rays are necessary to confirm a proper reduction.

We have found that certain positions will cause or relieve pressure on the cervical cord, sufficient to obstruct or open the cervical canal. We feel that manipulation can be done with greater safety if one has some gauge as to what pressure, if any, is being excited on the cervical cord. The number of cases when manipulation caused a sudden onset of paraplegia or death are probably far greater than the literature would suggest.

If one finds a complete block that cannot be relieved by gentle changes in the position of the head and neck, one must conclude that pressure on the cord is great or that edema of the cord is extreme. To continue strenuous manipulation in such cases is to invite further injury of the cord. We feel it far safer to maintain traction, with calipers placed in the skull, and do an open reduction and decompression.

The recurrence of dislocation is fairly common, and the author's use of turnbuckles incorporated by a cast is very ingenious. Our experience has been that the patient can seldom tolerate the pressure of a halter on the chin and back of the head. Skeletal traction causes little discomfort, and effective halter traction can be secured in a proper direction to maintain reduction.

PYODERMATOSES*

By Nelson Paul Anderson, M.D.
and
Samuel Ayres, Jr., M.D.
Los Angeles

Discussion *by Ernest Dwight Chipman, M. D., San Francisco; Franklin I. Ball, M. D., Los Angeles; Sophie A. Lurie, M. D., Los Angeles.*

The purpose of this paper is to discuss some of the pyogenic infections of the skin. These form a distinct group from an etiologic standpoint, being produced by organisms which have the skin as their normal habitat. The diagnosis of these conditions in most cases offers no particular difficulty. In some of them, such as impetigo, therapy offers no great problem, while in others, such as sycosis, even persistent treatment carried out over a period of years may fail to effect a cure. It is our desire, in presenting this subject, to stimulate discussion of the pyodermas and especially those characterized by their refractoriness to present-day therapy.

IMPETIGO CONTAGIOSA

The common types of impetigo contagiosa require no discussion in a paper of this type. Mention should be made of the annular or circinate type, which is so often mistaken by the general practitioner for a ringworm infection. The generalized bullous type of impetigo is infrequent, and even when it does occur we are perhaps too prone to consider the condition a pemphigus.

It is the secondary or consecutive types of impetigo which are sometimes very misleading. Thus we see an impetigo of the nape of the neck secondary to pediculosis capitis; an impetigo of the hands, or one that is fairly well generalized, is often seen as a complication of scabies. Such a secondary pyodermia may be so severe as to mask entirely the essential underlying condition. Many cases of dermatitis venenata, eczema, epidermophytosis, herpes simplex, and insect bites may present a secondary impetigo.

Impetigo of the new-born occurs more frequently in the lying-in wards of our hospitals than

---

Fig. 2.—Ecthymatous lesions of the legs. This is primarily an impetigo with deep ulceration.

we are willing to admit. Its complete eradication from a hospital nursery is often extremely difficult. And, further, it is a more frequent cause of infantile mortality than is apparent.

In regard to the therapy of impetigo, a few facts may be mentioned. Amoniated mercury still continues to hold a high position. Generally, its use in strengths of from 3 to 5 per cent is attended by a successful outcome. The use of stronger preparations, such as the official 10 per cent ointment, is often followed by a spreading of the impetigo or the production of a severe dermatitis venenata. We still see cases where tincture of iodin has been used in conjunction with mercurial ointments, with the consequent inevitable mercuric iodid dermatitis.

Sulphur is a much neglected remedy, so far as the pyodermias are concerned. It is of great value in 3 to 5 per cent strengths, not only in the simple impetigos, but particularly in cases occurring as a complication of scabies. Among other remedies which need be only mentioned here are ultra-violet light, x-rays, Alibour water, and the recently introduced preparation of a 1 to 500 solution of metaphen in flexible collodion. A 2 per cent aqueous solution of gentian violet is often of service.

ECTHYMA

Ecthyma may be regarded simply as a deep, ulcerating form of impetigo, usually involving the lower part of the legs. Practically all of the remarks pertaining to impetigo hold true for this condition.

SYCOSIS VULGARIS

This chronic persistent and stubborn perifollicular infection is most generally found on the bearded region of the face. However, it may also involve the eyebrows, eyelashes, scalp, axillae, and pubis.

Produced by the staphylococcus, this disorder takes a high position in its rebelliousness to all forms of therapy. At times it may be cured by the simplest therapeutic measures, while at other times even permanent alopecia produced by x-rays may fail to bring about a cure. In the stubborn cases, manual epilation should be practiced daily. Foci of infection in the nose, sinuses, tonsils, and teeth should be eradicated. It is interesting to note the conflicting advice given regarding shaving in this condition. Andrews[1] specifically states that "Barber's clippers should be substituted for the razor, shaving not being permissible." Ormsby[2] is very emphatic in advising daily shaving. Stelwagon[3] is even more emphatic when he says: "As soon as the inflammatory action has been lessened and, in fact, in almost all cases from the very beginning, shaving every day or every second day should be insisted upon as an essential part of the treatment. This will not be without pain at first, which is by no means unbearable; but after the first two or three shavings the operation is not especially painful. It materially aids in rendering the treatment effective and in shortening the time required for a cure, and this the patient soon recognizes himself. I value this so highly that I should decline to treat a case unless this measure were acceded to."

The recent introduction of oxychlorquinone ointment by Peck of New York represents the only new contribution to this most difficult therapeutic problem. Even this is not to be regarded as curative, for most patients are compelled to use the ointment more or less continuously. The value of x-rays, either in fractional or epilating doses, is often attended by success. Intravenous vaccines in increasing doses, the ultra-violet light in patients who have had the maximum allowable dosage of x-ray, and Alibour water wet dressings, all should

Fig. 4.—Pyogenic granuloma of the lip. This diagnosis was substantiated at biopsy. Several physicians had previously diagnosed this lesion as a carcinoma.

be mentioned. Occasionally a 75 per cent aqueous solution of ichthyol will give a striking result.

LUPOID SYCOSIS

This may be considered as a special type of sycosis vulgaris, and is characterized by its extremely chronic course, the presence of small to large atrophic areas of scarring, which are bordered by pustules and crusts. As the process advances, it causes a total destruction of the hair follicles and a permanent alopecia results. A special name is often applied when the eyebrows are alone involved, namely, ulerythema oöphrogenes.

The histologic picture is unique and fairly characteristic, revealing, as Unna pointed out nearly fifty years ago, a practically pure plasmoma.

INFECTIOUS ECZEMATOID DERMATITIS

This is a chronic resistant infectious eczema which often occurs consecutive to a discharging sinus, ulcer or abscess. About the ear it is often associated with a chronic otitis media; about the ankle, with a discharging varicose ulcer; about the face with a chronic discharge from the nose and eyes. Secondary eczematous eruptions occurring in the acute stages of an x-ray burn belong in this group.

Fundamentally, the eruption is probably the effect of an allergic hypersensitivity to toxins or bacteria contained in the irritating discharge from the original focus. The appearance of small grouped vesicles together with linear lesions occurring in scratch marks, its pruritus and, above all, its auto-inoculability and its failure to respond to ordinary measures, are characteristic. In some cases of this disease the ultra-violet light is of considerable value. At other times x-ray therapy is useful. In many of the cases which we encounter, White's Crude Coal Tar Paste has been of great value. Autogenous vaccines and 2 per cent aqueous gentian violet are useful auxillary measures.

GRANULOMA PYOGENICUM

These granulomatous lesions are undoubtedly secondary to an infection produced by the pyogenic cocci. Their pedunculated appearance, the tremendous hemorrhage which occurs when they are traumatized, and their tendency to recur unless completely removed, together with their semi- or apparently malignant appearance, are all factors which have made these lesions a cause of considerable confusion in the minds of all but dermatologists. Thus we frequently see a recurrent pyogenic granuloma of the lip being mistaken for a carcinoma. On the breast they are confused with true malignancies, and when they occur on the conjunctiva, as they undoubtedly do, the ophthalmologist considers them in the angiomatous group.

The importance of having histologic studies made of excised lesions is obvious. Many general pathologists are not at all familiar with the microscopic structure of these lesions, and hence the importance of each dermatologist having a knowledge of their histologic appearance, which is so characteristic.

Excision by the endotherm knife, or complete destruction of the lesion by the electrodesiccating current under novocain, is an accepted and effective treatment.

VEGETATING PYODERMIAS

We have seen one case of a blastomycosis-like lesion on the back of the hand which we feel belongs in this group. No papers on this subject have appeared in the American literature, although cases have been presented by Fox,[4] Schwartz,[5] and Traub.[6] The eruption begins as a small papular lesion, and gradually spreads to involve the dorsum of the hand from the wrists to the proximal phalanges. One or both hands may be involved, and the final picture is that of a chronic verrucus and vegetating, somewhat granulomatous-appearing growth. Clinically, it is very similar to a blastomycotic infection or to a verrucous tuberculosis cutis.

Glasser[7] and Gougerout, among others, have described cases in the French literature. The condition is apparently a vegetating and verrucous pyodermia of streptostaphylococcic origin. Histologic examination has shown a simple inflammatory reaction in the cutis, with an irregular acanthosis, a branching of the rete pegs and a verrucous structure of the epidermis.

RECALCITRANT PUSTULAR ERUPTIONS

Mitchell,[8] Andrews,[9] and Lehmann[10] in the United States, and Barber[11] in England, have been particularly active in calling our attention to a condition characterized by the formation of small vesicopustules symmetrically placed on the palms and soles, and which exhibit a marked stubbornness to practically all forms of treatment. The eruption particularly involves the mid-portions of the palms and the instep of the feet. The lack of involvement of the fingers and toes, and especially of the interdigital spaces, is striking, although occasionally one sees a small group of pustules on the tips of the toes. Eventually, with the drying of the pustules there is a marked and characteristic exfoliation. New attacks and exacerbations occur from time to time, and are characterized by the formation of new pustular lesions either within the patch or at its periphery.

Generally, as pointed out by Andrews, these patients have some obvious focus of infection in other parts of the body, and often this focus is a severe one. One of our patients had a very definite focus of infection in the antrum. In another patient, careful search failed to reveal any such focus.

In general we agree with Andrews that these cases belong in a group by themselves and are probably not pustular psoriasis as maintained by Barber. We also agree that no permanent cure is obtained unless attention is paid to the underlying cause. We do feel, however, that x-ray is a valuable agent of therapy. In addition to x-ray, we also use crude coal-tar paste according to the formula of C. J. White.

℞

Crude coal tar	4
Zinc oxid	2
Cornstarch	15
Petrolatum	15

Anthralin in our hands has proved of no value in these cases.

CONCLUSIONS

1. We have briefly discussed some of the common and acute pyogenic infection of the skin.

2. The more chronic and resistant pyodermias have been briefly discussed, with special reference to treatment.

DISCUSSION

Ernest Dwight Chipman, M.D. (2000 Van Ness Avenue, San Francisco).—The scope of this paper is so wide that it allows a corresponding amplitude of discussion.

In general, it may be observed that a large percentage of the pyodermata are consecutive to simple pruritus or to a pruritic dermatosis. The impetiginization of a simple eczema and the occurrence of impetigo, ecthyma or furunculosis complicating scabies are familiar examples of this. Largely the lesions are the result of infection through scratching.

As to the causative organisms, it is important to note, particularly if vaccine therapy is contemplated, that impetigo certainly, ecthyma probably, and infectious eczematoid dermatitis possibly are the result of streptococcic invasion, although staphylococci may be also present as secondary invaders. Folliculitis and furunculosis are usually purely staphylococcic in origin.

It is gratifying that the writers advocate the use of mild forms of ammoniated mercury in the treatment of impetigo; also that they warn against the use of mercurials following the application of iodin. I have seen impetigo in infants do very badly on ten per cent white precipitate ointment, and recover promptly when a one per cent salve was substituted. It is astonishing, also, how many patients appear after having made one or more applications of iodin, thinking that probably they were subjects of ringworm.

As to the treatment of impetigo the authors properly emphasize the value of sulphur in some cases. The same result may be reached with a three per cent calomel ointment. By and large, ammoniated mercury is probably the most favored remedy; but whatever the medicament, the final outcome depends largely upon the attention to detail in its application. While it is obvious to us, it is necessary to impress strongly upon the patient the necessity of removing all crusts and the turning back of epidermal collarettes prior to the application of the prescribed remedy.

The authors raise a fine point in the treatment of common sycosis as to the value of shaving. I do not believe a hard-and-fast rule can be drawn; for, while perhaps most cases respond to daily shaving followed by immediate applications of one sort or another, there certainly remains a group of cases in which the defensive forces of nature will do their work if given a fair chance. Lesions which are healing nicely under a crust do better with little interference. In certain cases a nicety of judgment is required, and the ability to determine properly when to interfere and when to refrain, is worth much more than hard-and-fast ruling.

Along the same line the subject of furunculosis should be mentioned. Possibly this topic was not discussed by the authors because it is worthy of an entire paper by itself. As with other pyodermata, furuncles appear as a result of scratching. Almost invariably furuncles involving the nucha denote an itching scalp which has been scratched. Here, besides the attack on the furuncle itself, the scalp and the finger nails should receive attention.

At present the trend seems toward more conservatism in treating boils—that is, allowing as much or more for the subject's resistance as for active interference It must not be forgotten, moreover, that in certain areas, notably about the face, furuncles are potentially fatal. Finally, the action of x-rays in aborting boils in their early stages should be emphasized.

⁂

Franklin I. Ball, M. D. (6253 Hollywood Boulevard, Los Angeles). — As Doctors Anderson and Ayres have indicated, the pustular dermatoses do indeed demand our attention, more from the therapeutic point of view, because of their frequent refractoriness, than from the diagnostic side.

Impetigo contagiosa is perhaps the greatest of our concern, because of its widespread occurrence and its consequent economic loss of working-time in adults, and loss of school days among children. Although the time-honored ammoniated mercury still holds its high position in our treatment of impetigo, the new occlusive dressing, with elastoplastic tape, merits serious consideration as a means of shortening the duration and the contagious nature of this infection.

We agree with Doctors Ayres and Anderson in recommending the use of Peck's oxychlorquinon ointment in the treatment of sycosis vulgaris, and wish to further encourage its use, as we have had more success with it than with any other locally applied therapy. X-rays are to be held in high regard, also, in the treatment of sycosis, and their use along with the oxychlorquinon ointment often makes for the best combination and result. We have also used the above ointment in the treatment of chronic infectious eczematoid dermatitis with gratifying results, and recommend its use here.

Of the vegetating pyodermias, we have seen a number and feel that they are of a superficial nature and are closely related to granuloma pyogenicum. As to their treatment we feel that when they do not respond to local applications or similar measures, they may be effectively treated by destructive endothermy.

⁂

Sophie A. Lurie, M. D. (1025 Story Building, Los Angeles). — I presume that this thoughtful analysis of pyodermatoses will not reveal any discrepancies of opinion of its value among dermatologists.

In my estimation, the most important point to stress in this paper is the idea of distributing a dermatological conception to non-dermatologists, especially to the general practitioner.

While working on a huge clinical material, we have seen a number of ill complications in primary and secondary pyodermas, as a result of a false interpretation of a dermatological diagnosis and treatments.

Considering the methods of treatment which are applied by the authors, I am fully agreed with them.

I, personally, use with gratifying results, especially in bullous forms of pyodermas, applications, compresses and local baths of potassium permanganate solution 1:4000, or in exquisite cases I use local immunization, by means of compresses, of Besredka's antivirus (Abbott's).

⁂

Doctor Ayres (Closing). — Doctor Anderson and I wish to thank the discussers for their remarks. Again touching on the treatment of the acute pyodermas, especially impetigo, furuncles, and pyogenic infections secondary to other conditions, we feel that, in our experience, the most useful single application is continuous wet dressings of Alibour water, an old French preparation of copper and zinc sulphate in camphor water.

One condition which I believe was not touched on was a rather uncommon granulomatous occurrence, usually caused by a combination of an anaerobic streptococcus and a staphylococcus. This type of lesion generally begins as an acute subcutaneous abscess which opens and spreads with an undermining border, a beefy-looking granulomatous base and a purulent discharge. This likewise is extremely rebellious to all forms of therapy. One patient whom we treated for over a year finally yielded to maggot therapy, while another, who is still under treatment, has resisted everything we have tried.

CANCER OF THE THYROID GLAND[*]

A REPORT OF TEN CASES

By Francis B. Settle, M.D.
Long Beach

Discussion *by William E. Costolow, M. D., Los Angeles; Robertson Ward, M. D., San Francisco.*

The occurrence of the following ten cases of cancer of the thyroid in a private surgical practice during a period of thirteen and one-half years in Southern California, where endemic goiter is not prevalent, seems to be of sufficient interest to warrant reporting.

REPORT OF CASES[†]

Case 1.—Mrs. E. A. B., age 64, born in Illinois, was first examined in March, 1923. There was a history of goiter for twenty years, with a definite and gradual enlargement in the past three years. Hyperthyroidism was evidenced by loss in weight, marked nervousness, increased appetite, and palpitation of the heart with some cardiac damage. Treatment was refused. This patient was seen again in July, 1924, complaining of difficulty in swallowing and breathing. There had been a recent rapid increase in size of the left lobe of the thyroid, with definite regional lymph node involvement. Diagnosis of cancer of the thyroid was made. At operation, July 6, 1924, the left lobe of the thyroid, consisting of one large, firm, well-encapsulated, substernal tumor, and two small hemorrhagic cysts, was removed. The pathological diagnosis was "adenocarcinoma of the thyroid." Postoperative x-ray therapy was given. In September, 1924, there was no evidence of recurrence and the regional nodes had disappeared. Her attending physician reported that she died January 17, 1927, of paralysis agitans and showed no evidence of recurrence of the thyroid malignancy.

* * *

Case 2.—Mrs. E. O., age 42, a graduate nurse, born in New York, was examined in February, 1924, because of a small, freely moveable tumor just anterior to the left sternomastoid muscle at the level of the thyroid cartilage. The thyroid gland was not palpable. A small fatty tumor had been removed from the neck in 1905. At operation March 10, 1924, a small cystic tumor mass one and one-half centimeters in diameter, entirely independent of the thyroid gland, was removed from the left side of the neck. Tissue diagnosis was "papillary adenocarcinoma of aberrant thyroid tissue." This patient was referred to a radiological clinic for further treatment. In November, 1925, a large benign uterine fibroid was removed by a New York surgeon. A year later this patient was again examined, and there was no apparent recurrence of the aberrant thyroid tumor and the thyroid gland was normal. On December 18, 1933, a definite recurrence of the aberrant thyroid tumor was noted. X-ray treatments were again given. By February 16, 1934, there was a rapid extension to the entire left side of the neck. The growth apparently became radio-resistive and x-ray therapy had no beneficial effect. A large elongated tumor could be felt in the left lobe of the thyroid gland. X-ray examination showed a marked destruction of the cervical vertebrae. Death occurred in April, 1934. Autopsy was not obtained.

* * *

Case 3.—Mrs. W. E. S., age 51, born in Nebraska, was examined in October, 1924, because of a rapidly recurring goiter of three weeks' duration. There was marked exhaustion, some loss in weight, nervousness, and palpitation. She had some difficulty in swallowing solid food. There was a history of goiter at puberty, and five years previously a tumor the size of a walnut had been removed

---

[*] Read before the General Surgery Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

[†] Owing to lack of space, only five of the case reports are given. Others will appear in the reprints.

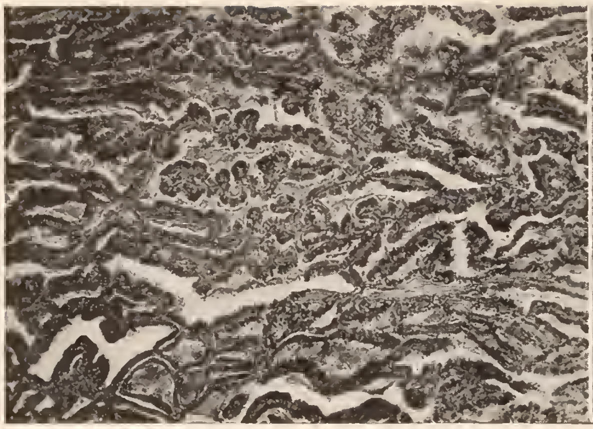

Fig. 1.—Papillary adenocarcinoma of aberrant thyroid tumor.

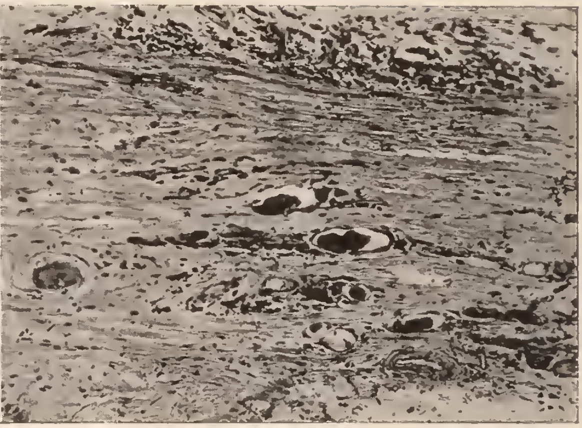

Fig. 2.—Tissue showing many thyroid cells from pathological fracture of right femur.

by a local surgeon. No tissue examination was made at that time. Examination revealed a hard, nodular, firmly fixed mass, about the size of a small lemon, just above the center of the former operative scar. This tumor seemed to extend into the mediastinum and to interfere with deglutition. There were numerous palpable posterior cervical glands. X-ray of the chest showed nothing abnormal. At operation, October 21, 1924, a firm, nodular tumor mass, 3½ to 4 centimeters in diameter, which was attached to the trachea and surrounding structures, was removed with considerable difficulty, leaving what appeared to be a part of the isthmus of the thyroid gland. Pathological diagnosis—"rapidly growing, mixed-cell carcinoma of the thyroid gland." This patient was given a considerable amount of x-ray treatment during the following three months. On January 11, 1935, this patient consented to a photograph, and appears to be free from any recurrence or metastasis.

* * *

Case 4.—Mr. A. M., age 58, born in Sweden, was first seen in June, 1925, with a history of goiter for about twenty-five years. In December, 1924, he had developed an acute hyperthyroidism, with a gastro-intestinal and mental crisis, and a metabolic rate of plus 104. Under careful medical supervision by a local physician this patient had made considerable improvement, and at the time of examination the basal metabolic rate was plus 15. The thyroid showed a diffuse enlargement on the right side, with a nodular enlargement on the left. On July 2, 1925, a test ligation on the right side was done. General reaction was favorable, but there was an apparent rapid increase in the size of the thyroid gland, the left lobe becoming markedly nodular; and on July 13 the left pole was ligated and tissue for examination recovered. Pathological diagnosis showed a rapidly growing carcinoma of the thyroid gland. This patient's hyperthyroidism became acute. He did not now respond to routine preoperative measures. The thyroid grew rapidly, and the patient died early in August of acute hyperthyroidism and pressure from the rapidly growing carcinoma of the thyroid. Before death the thyroid became firmly fixed, a number of regional lymph nodes were apparent and, although x-ray examination and x-ray treatment were refused, there was evidence of pulmonary and hepatic involvement. Autopsy was refused by the family.

* * *

Case 5.—Mrs. W. B., age 46, was first seen August 4, 1927, because of an unusually large tumor of the right lobe of the thyroid. There had been a preëxisting nodular goiter for three or four years. Two years previously a paroxysm of coughing had been caused by a foreign body in the larynx, and immediately following this there was a marked and noticeable enlargement of the thyroid gland. Examination revealed a large, nodular, freely movable thyroid involving both lobes and the isthmus. At operation, August 8, a subtotal thyroidectomy was done. The thyroid was found to be large, nodular, and contained one large hemorrhagic cyst. Convalescence was uneventful. Three weeks later this patient was readmitted to the hospital with a diagnosis of acute appendicitis. On exploration of the lower right abdomen, a large hemorrhagic ovarian cyst was found and removed, together with an acutely inflamed appendix. Careful pathological examination of the cystic tumor removed from the pelvis showed no evidence of malignancy. The thyroid tissue was again examined and no evidence of malignancy was found. In 1929 this patient sustained a fracture of the right femur. Union was delayed, and at operation, by another surgeon, tissue was recovered which on section proved to be thyroid tissue, indicating a probable primary neoplasm in the thyroid gland. We have been unable to follow this case because the patient soon left for the East and we have had no further contact with her.

CLINICAL MATERIAL STUDIED

During this period of thirteen and one-half years approximately seven hundred patients were observed, presenting some abnormality of the thyroid gland. The incidence of cancer to the number of patients examined was 1.43 per cent. This corresponds very closely to the incidence of cancer as observed in other sections of the country. It is, however, higher in localities where endemic goiter is prevalent. The age incidence corresponds very closely to malignancies in general; of the ten cases, one occurred in the fourth decade, two in the fifth, five in the sixth, and two in the seventh. The youngest patient was thirty-three years of age and the oldest sixty-seven years of age. There were six females and four males.

A history of preëxisting goiter was observed in nine of the patients, one patient having noted a goiter for only four months. The average duration was approximately fifteen years. Case 2, presenting a papillary adenocarcinoma of aberrant thyroid tissue, developed a tumor of the left lobe of the thyroid before death. Case 8 proved to be a secondary invasion of the thyroid following a primary malignancy of the left breast.

A clinical or presumptive diagnosis was made in seven of the cases, and the diagnosis depended upon a microscopical examination of the tissue in the remaining three. The appearance of a rapidly growing tumor of the thyroid gland, a rapid increase in the size of a preëxisting tumor, or a rapid and repeated recurrence, is always suggestive of malignant changes. Pain, difficulty in breathing and swallowing, huskiness of the voice

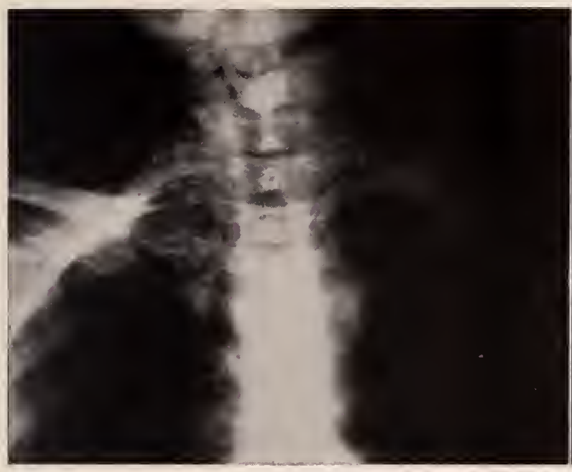

Fig. 3.—Large tumor left lobe of thyroid.

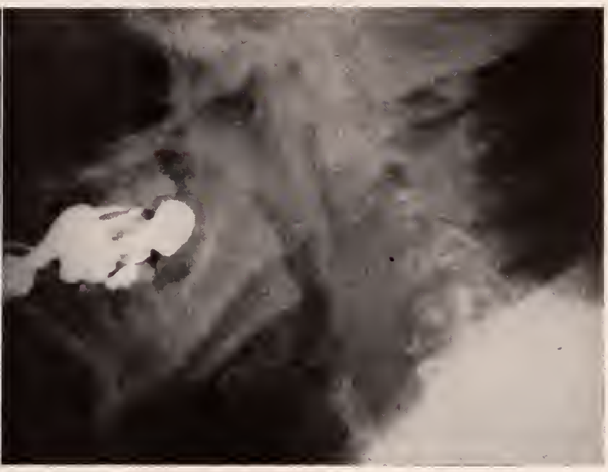

Fig. 4.—Destruction of cervical vertebrae.

and fixation of the tumor were common symptoms. There are no signs or symptoms by which early malignant changes can be recognized; for, commonly, it is only after the cancer has perforated the capsule of the gland, and has involved the surrounding structure, that a positive clinical diagnosis can be made.

THE MALIGNANCY ELEMENT

The function of the thyroid throws no light upon the differential diagnosis of malignancy; however, malignant changes were found incident to surgical treatment of toxic nodular goiter in a relatively high percentage of the cases reviewed in the literature. Five of the ten cases had definite toxic symptoms, one having suffered a gastrointestinal and mental crisis a few months before there was evidence of malignancy.

Primary lesions of the thyroid are for the most part epithelial in origin. The following types of malignancy were observed: there were two adenocarcinomas, one papillary adenocarcinoma of aberrant thyroid tissue, one mixed cell carcinoma, two carcinomas not classified, two probable malignant adenomas, one case resembling both carcinoma and sarcoma, and one secondary invasion of the thyroid from a primary cancer of the breast.

Many attempts have been made to classify malignant epithelial tumors occurring in the thyroid gland; however, most pathologists and surgeons agree that there are distinctive features which lend themselves to at least clinicopathological groupings. The different classifications vary for the most part as regards nomenclature rather than clinical features. Graham has called attention to the fact that the thyroid has certain peculiarities not common to other organs or tissue. In no other organ do malignant tumors of epithelial origin proceed so directly on a basis of a preëxisting benign tumor. In no other organ do malignant epithelial tumors (except chorionepithelioma) exhibit such a high incidence of metastasis through the blood stream. In no other organ does the histologic appearance of the cells and tissue, both of the primary carcinoma and its metastases, so closely resemble benign parent tissue in such a significant percentage of cases. He further believes that the determination of malignancy depends more upon the blood vessel invasion than on the morphological structure of the cells; however, a great many pathologists rely upon the usual criteria, that is, structural arrangement and cellular differentiation.

Cases 1 and 10 were diagnosed definitely as adenocarcinomata. This type usually arises from a preëxisting benign tumor, though it may occur in a nongoiterous gland, and includes mixed cell, round cell, spindle cell, and small or giant cell types, and in the more malignant lesions may resemble sarcoma. For this reason Cases 3, 4, 6, and 7 may be termed diffuse adenocarcinomas. Clinically, this type may spread by way of the blood stream, lymph spaces, or by direct extension.

PAPILLARY ADENOCARCINOMA

Papillary adenocarcinoma, commonly arising from a preëxisting benign tumor, is of low-grade malignancy and shows a marked predilection for invading lymph spaces and involving cervical lymph nodes. Distant metastases rarely occur. This type of malignancy resembles, clinically and pathologically, papillary adenocarcinoma of the ovary. Both are of low-grade malignancy and both are radiosensitive, a property which, for the most part, is not common to carcinomas of low grade situated elsewhere. Case 2, that of a papillary adenocarcinoma of aberrant thyroid tissue, illustrates this type of lesion.

Leech and Smith believe that aberrant thyroid tumors arise in cell masses which develop from the posterior portion of the pharyngeal complex, so-called fifth pouch, and fail to fuse with the gland proper. It has been suggested by Pemberton that these tumors may not be embryological defects, but may be deposits of malignant cells from a primary lesion occurring in the thyroid gland. The case herein presented, while showing no early involvement of the thyroid, did develop a large tumor of the left lobe of the thyroid before death. Diagnosis of these tumors is important because they are usually of a papilliferous type, are very radiosensitive and respond well to treatment.

MALIGNANT ADENOMA

Malignant adenoma or adenocarcinoma of fetal adenoma is said to arise from a malignant transformation of a benign fetal adenoma. Its morphology is not uniform, but varies within wide limits. It is for the most part of low-grade malignancy, and tends to metastasize early by way of the blood stream. This feature has been demonstrated at operation by the presence of sizeable masses of carcinomatous tissue in the veins of the thyroid gland. Invasion of the capsule does not occur until late, and often the malignancy is first discovered as a metastatic lesion. Case 5, that of a pathological fracture of the femur, had previously shown no evidence of malignancy in the thyroid gland which had been removed eighteen months before. It is, undoubtedly, this type of tumor that has been responsible for the frequent occurrence of the so-called metastatic benign adenoma of the thyroid. Simpson has proved rather conclusively that all cases of so-called metastatic benign adenomata of the thyroid, when completely examined, show definite primary lesions in the thyroid gland. Case 9 is also classed as a malignant adenoma. Clinically, this patient presented a rapid recurrence of the original tumor with marked involvement of the cervical lymph nodes which disappeared after x-ray therapy. Microscopically the original tissue resembled fetal adenoma. It is generally believed that benign adenomatous goiter does not respond so readily to irradiation therapy.

The thyroid gland may be involved secondarily as shown by Case 8, that of a rapidly invaded lesion resembling mammary tissue. This patient had had a preëxisting primary adenocarcinoma of the left breast.

METASTASIS

Metastasis occurred in each of the above ten cases. Regional lymph nodes alone occurred in four, mediastinum and lungs were involved in four, and in only one case was the bony skeleton involved. Dinsmore and Hickens, in a study of 124 cases of cancer of the thyroid with metastasis, found the incidence as follows: cervical lymph nodes 94, lungs 36, bones 18, brain 5, axillary lymph nodes 3, liver 2, soft tissue 2, and intra-abdominal 1, showing a marked preponderance of metastasis in the regional lymph nodes. Pemberton found cervical lymph nodes involved in 69 per cent of cases observed, lung metastasis in 24 per cent, and bones in 26 per cent. Eisen, Clute and Warren, and Pemberton have reported cases of metastasis into the heart.

TREATMENT

The treatment of the ten cases consisted of surgery, and x-ray in four cases, surgery alone in two cases, and no treatment in three. In one case a decompression operation was attempted too late to be of benefit.

It is significant to note that all authors agree that 90 per cent or more of malignant changes of the thyroid occur upon preëxisting benign tumors. Coller found clinical and pathological evidence of preëxisting adenomatous goiter in 98.8 per cent of ninety cases. Pemberton, Poole, Clute, Toland, and others, have suggested the advisability of removing all tumors of the thyroid occurring in the second and third decades of life as a preventive measure. Coller and Baker consider endemic goiter as a definite, precancerous lesion, and because of difficulties in diagnosis of early cancer and the slight chance of cure when a clinical diagnosis can be made, believe that all adenomatous goiters should be removed when diagnosed after the age of twenty-five.

In a study of approximately two thousand cases reviewed in the literature, 41 per cent were diagnosed clinically, and less than one-half of these cases responded to any type of treatment. The fact that 50 per cent or more were recognized by pathological examination alone suggests the necessity of careful microscopical examination of all goiterous tissue removed; for it is this type of case that affords uniformly good results if proper treatment is instituted. Palliative measures, such as decompression operations followed by irradiation, have prolonged life in a considerable number of cases in the apparently hopeless individuals.

Metastasis, either local or remote, does not necessarily preclude treatment. This is particularly true of the papilliferous type of tumor. Many cases have been reported in which a combination of surgery and irradiation have brought about an arrest and an apparent cure.

In general the type of treatment for cancer of the thyroid should be based upon the stage of advancement at the time of recognition. In a recent report of the committee on thyroid tumors, it has been suggested that these patients be placed in three distinct groups and treated accordingly. First, those in whom the diagnosis is made before operation; second, those in whom the diagnosis is made at operation; third, those in whom diagnosis is made by pathological examination. Group one, who are without demonstrable distant metastases, especially to the bones, should have as complete an electrosurgical removal of the tumor as is possible without damage to the surrounding structures. This should be preceded and followed by deep x-ray or radium therapy. In the cases in which the technical difficulties of removal of the tumor seem too great, the procedure may be reversed or x-ray therapy alone may be resorted to. Group two, in whom malignancy is recognized first at the operating table, usually have malignant adenoma with penetration of the capsule of the tumor. A total lobectomy is indicated in these cases, with the removal of as much surrounding portions or tissue of the other lobe as is necessary to eradicate the growth. A course of intensive x-ray therapy should follow the operation, beginning before the patient is discharged from the hospital. In group three, in which the diagnosis depends solely upon the microscopic examination of the tissue, the malignant growth is usually entirely within the capsule of the adenoma. In the large majority of these cases the primary operation is curative and no further treatment is indicated. If, however, pathological examination shows that the tumor has penetrated the capsule of the adenoma, a second operation should be done immediately, with removal of the entire lobe from which the malignant adenoma arose. Postoperative irradiation therapy is advisable.

RESULTS

Of the cases treated surgically and followed with irradiation therapy, one patient is living and well after ten years; one died after ten years, of recurrence and rapid metastasis; one died at the end of two and one-half years from intercurrent illness, with no evidence of recurrence or metastasis; one is alive and well at approximately two years after treatment, with no evidence of recurrence. One patient died two months later of rapid local recurrence and metastasis of the lungs and pleura, and one died immediately following decompression operation. Of the cases not treated two are known to have died within a short time after recognition, and the third case has not been followed.

IN CONCLUSION

No conclusions can be drawn from so small a number of cases; however, it can be said without contradiction that all tumors of the thyroid gland should be considered potentially malignant until proved otherwise.

DISCUSSION

William E. Costolow, M. D. (1407 South Hope Street, Los Angeles).—To discuss the rôle of irradiation in the treatment of carcinoma of the thyroid, it is necessary to consider the various types of thyroid malignancy, both from the clinical and histologic standpoints. For certain clinical varieties, there are corresponding histologic classes which give a clue as to the probable method of invasion of the malignancy and the prognosis.

It has been shown in most of the large series of cases reported that the majority of carcinomas of the thyroid are in the lower grades of malignancy. Case 2 in Doctor Settle's group illustrates one of the low-grade types, which constitutes a large group of the thyroid malignancies—the papillary adenocarcinoma. This case, which we treated for Doctor Settle, illustrates the clinical course very well in this type of tumor—a radiosensitive, slowly growing, slowly metastasizing tumor, ending after ten years in spinal metastasis. These growths are mostly grades 1 and 2 of Broder's classification; but they are, nevertheless, radiosensitive, and probably partially due to the fact that the cells of the thyroid gland appear to be naturally more radiosensitive than those in some other glandular organs. In Pemberton's series of 137 patients living more than five years, 58 per cent were of this histologic type. Preoperative irradiation is of great value in this group, often rendering extensive inoperable growths operable. Radium implantation has also been used successfully in the papillary adenocarcinomas, partial surgical resection and implantation of the remainder of the growth being done. The radium implantation is possible in this papillary type, which metastasizes through the lymphatics, chiefly, but would be a contraindicated procedure, for instance, in an adenocarcinoma in a fetal adenoma, where metastasis occurs very early in the blood-vessel walls and throughout the blood stream. Radiation alone has produced complete five- and ten-year arrests in the papillary type of growth.

The adenocarcinoma in the fetal adenoma is quite radiosensitive. This growth, however, invades the blood stream early, and produces a high percentage of distant metastasis in the bones. These distant metastases in bone frequently show complete regression following irradiation.

The high-grade malignancies of the thyroid are, fortunately, the smallest group. The diffuse, high grade, fulminating growths, with rapid onset and metastasis, have been described under various classifications as small, round, spindle and giant cell carcinomas. This group is hopeless from either a surgical or radiotherapeutic standpoint, and invariably goes on to a fatal termination. Apparently this wildly growing growth is entirely radioresistant.

In planning the proper treatment of carcinoma of the thyroid it is most important to classify the case, by pathologic examination as to grade and type of malignancy, and by clinical grouping; because it is only by a consideration of these two factors that proper future treatment can be planned, and a clue as to the final prognosis be determined. Irradiation has been found to have a definite rôle in the treatment of carcinoma of the thyroid, both alone and in combination with surgery.

⁂

Robertson Ward, M. D. (384 Post Street, San Francisco).—I am in complete agreement with the only conclusion which Doctor Settle has felt justified in drawing from his small series of cases, namely, that all tumors of the thyroid should be considered potentially malignant, until proved otherwise. To prove such benignancy is often most difficult, as some of his cases demonstrate. It is well known that pathologic examination is proverbially unreliable in thyroid malignancy, especially from the point of view of prognosis. Cases 5 and 9 in Doctor Settle's series are excellent examples of this difficulty. In neither of these instances could malignancy be revealed by pathologic examination, yet one patient had metastases to the bones within two years of operation and the other had local recurrence within three months, was relieved by x-ray therapy and now has recurrent masses high in the neck less than two years after operation.

Other interesting features are brought out by this study. From a similar study of sixty patients operated upon at the University of California Hospital, upon whom I have a complete follow-up, we have found that a five-year period of freedom from recurrence does not constitute a cure. Case 2 of Doctor Settle's series bears this out, inasmuch as there was a recurrence of a papillary-cyst-adeno-carcinoma nine years after an apparent cure by surgery and radiation. Upon its second appearance this tumor was absolutely resistant to radiation, and the patient died within four months. What biologic change is responsible for this state of affairs? It would be interesting to have a biopsy of the recurrent tumor to compare with the original material. It is only from careful studies such as Doctor Settle's, and equally careful follow-ups, that these questions are going to be answered.

I am particularly interested in Case 3 of this series. This patient is living and well without apparent recurrence ten years after operation. The pathologic picture was one of mixed cell carcinoma which, in my experience, has been universally fatal and completely resistant to radiation. This is another example of the inconsistency of thyroid malignancy. Case 7 illustrates the extreme difficulty in distinguishing between some cases of chronic thyroiditis and malignancy. We had, in our series, an almost exact parallel in a patient who died following a sternal decompression. In our case also the pathologic diagnosis was far from convincing as to the actual presence of malignancy. In Case 6 the epidermoid carcinoma showed a consistent lack of response to therapy and was of somewhat doubtful thyroid origin, while in Case 8 the invasion of the thyroid was definitely secondary.

In addition to the inconsistency of thyroid malignancy what other conclusions can be drawn from this study? First, 90 per cent of these neoplasms arose from an already pathologic thyroid, thus suggesting the precancerous lesion. Secondly, an average duration of preëxisting goiter for fifteen years before the probable onset of malignancy shows conclusively that there is no factor of safety in a long duration of goiter without apparent change, but rather that the danger of malignant degeneration increases with the years. Thirdly, 70 per cent of the patients showed a rapid or definite period of growth very suggestive of malignancy, especially in the six cases in which goiter had been present for many years; and, finally, all four patients in whom the diagnosis was made before operation are dead.

We are grateful to Doctor Settle for placing material at our disposal which points so definite a moral. If pathologic examination of specimens removed at operation is not entirely dependable for diagnosis of malignancy, how much less reliable is a clinical examination in settling this point. Now we add the knowledge that, in the series under discussion, all patients who waited for a clinical diagnosis are dead as a result of the disease. It seems evident that our duty to the patient who consults us regarding a nodular goiter is to explain the possibility of a malignant degeneration and advise surgical removal which carries an almost nonexistent mortality in experienced hands. We should, at least, insist upon a semi-annual check-up and give instructions to the patient to report for immediate examination at the first sign of change in the gland. There is no justification for the advice to forget the goiter on the supposition that it is now, and will remain harmless.

AMPUTATION OF THE THIGH*

A NEW AMPUTATION IN THE DISTAL PORTION OF THE LOWER THIRD OF THE THIGH

By C. Latimer Callander, M.D.
San Francisco

Discussion *by Hugh Jones, M. D., Los Angeles; E. W. Cleary, M. D., San Francisco.*

This report of an amputation through the distal extremity of the femur has a sufficient number of novel features to justify its description as a new operation.

ESSENTIAL DETAILS OF THE OPERATION

The essential details of the operation, in summary, are as follows. The anterior flap includes the soft tissues of the upper part of the leg, as far as the level of the tibial tuberosity, while the posterior flap is a little longer and extends well down on the gastrocnemius muscle. The popliteal vessels and nerves are ligated through an amuscular and an avascular cleavage plane on the mesial aspect of the low thigh. All of the hamstring muscles are severed at their tendinous insertions on the tibia, and the femur is sectioned in the condylar flare, a centimeter or less proximal to the adductor tubercle. The patella is dissected from the anterior flap from the joint side, leaving the rectus femoris tendon in the floor of the patellar fossa to act as an end-bearing buffer for the femur. No primary coapting sutures are used throughout the operation, save four to six skin-clips or sutures, which hold the flaps roughly in position. As the edges of the flaps unite, the posterior flap retracts gradually, but very extensively, until the femur occupies the patellar fossa snugly, and the suture line is located well up behind the stump-end.

The advantages which this operation offers over other lower-third femur amputations, including the Gritti-Stokes operation, and the simplicity of the procedure, warrant a detailed description of the operative technique and an analysis of the results thus far obtained.

DESCRIPTION OF OPERATION

This description records the stages of this amputation in the lower left femur. The patient is placed in the dorsal decubitus position, the knee of the diseased extremity is flexed slightly, and the leg is elevated a little above the horizontal on one or two sand bags. No tourniquet is applied. The surgeon stands on the side opposite the affected extremity and faces the medial aspect of the thigh and knee to be operated upon. He maintains this position throughout the operation, because the essential steps are directed through a medial approach to the popliteal space. The operative work on the lateral part of the low thigh and knee are accomplished readily by rotating the knee medially.

The skin incisions, outlining the slightly unequal anterior and posterior flaps, are at the same level as the incisions which sever all the deeper soft parts. The incision on the medial aspect of the thigh begins at a point three finger-breadths proximal to the most prominent part of the medial femoral condyle, and runs horizontally distally in the palpable groove between the vastus medialis and the sartorius muscles. With the knee in partial flexion, this groove can be defined readily. After deepening the incision to the enveloping or deep fascia of the thigh, the adductor tubercle of the medial femoral condyle, and the tendon of the adductor magnus muscle, which inserts on it, can be palpated. The skin incision continues distally over the medial epicondyle, sweeps forward and crosses the anterior surface of the tibia at the anterior tibial tuberosity, the point of insertion of the quadriceps extensor tendon.

The thigh then is rotated medially (*i. e.*, toward the surgeon). The skin incision on the lateral aspect of the leg begins at a point three finger-breadths proximal to the lateral femoral condyle in the palpable groove between the tendon of the tensor fasciae latae (iliotibial tract) and the biceps femoris muscles. The incision must be made very close to the tensor fasciae latae tendon in order to avoid the muscular fibers of the biceps. Continuing distally over the lateral epicondyle, the incision extends forward to meet the medial incision at the anterior tibial tuberosity, thus outlining the anterior flap of the amputation.

Corresponding incisions from each femoral epicondyle are carried obliquely, posteriorly, and inferiorly until they meet on the calf of the leg, at a point a little inferior to the level of the anterior tibial tuberosity. This is the posterior flap incision, and it is deepened to the fascia on the gastrocnemius muscle. Thus are outlined two long amputation flaps, the posterior a little longer than the anterior. Each flap partakes not only of the soft parts of the lower thigh, but of a considerable portion of the soft tissue of the leg.

Attention again is directed to the medial aspect of the thigh and knee. The horizontal portion of the medial incision, common to both flaps (*i. e.*, that portion lying between the vastus medialis and the sartorius muscles) is deepened through the deep fascia of the thigh. Division of this powerful fascial layer, which is the only strong struc-

Read before the General Surgery Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

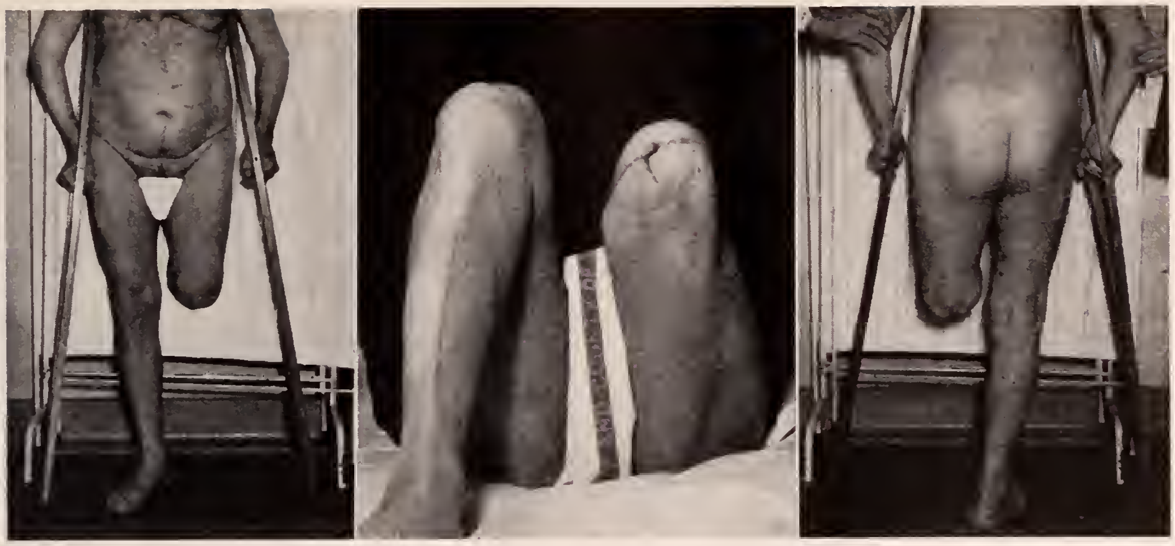

Fig. 1.—Anterior, posterior, and close-up views of the amputation stump. Note the extreme length placement of the suture line.

ture in the medial wall of the popliteal fossa at this level, affords ingress to the popliteal space. The left forefinger, now inserted shallowly into the popliteal space, frees the medial hamstring tendons to their tibial insertions by blunt dissection. At this juncture these tendons are divided in the order named—sartorius, gracilis, semimembranosus, and semitendinosus. During this dissection no fleshy portion of any of the medial hamstring muscles nor any part of the vastus medialis muscle need be exposed, much less severed. The severed hamstring tendons retract at once into the aponeurotic and areolar tissue of the posterior flap, and are not dealt with again. Further exposure is gained by severing the tendon of the adductor magnus muscle at its attachment to the adductor tubercle. Free access to the vasculoneural contents of the popliteal space thus is afforded. Moderate flexion of the knee relaxes the popliteal vessels and nerves, and favors their manipulation. With a finger now inserted more deeply into the popliteal space and kept close to the posterior surface of the femur, the popliteal artery and vein are withdrawn easily to a level flush with, or even outside of, the skin incision. Here they are clamped, ligated, and divided as near the superior apex of the popliteal space as is convenient. The tibial (internal popliteal) and common peroneal nerves then are drawn readily into the wound as one trunk and are anesthetized, ligated, and divided. Each of the components of the nerve bundle is injected with absolute alcohol to prevent neuroma formation, and the stump is allowed to retract into the proximal recess of the popliteal space.

The partly flexed knee now is rotated toward the operator, and the lateral longitudinal skin incision is deepened through the deep fascia of the thigh. The incision is carried through the deep fascia as far as the insertion of the biceps muscle on the head of the fibula, where the biceps tendon then is severed. At this stage of the operation the popliteal space may be opened widely from

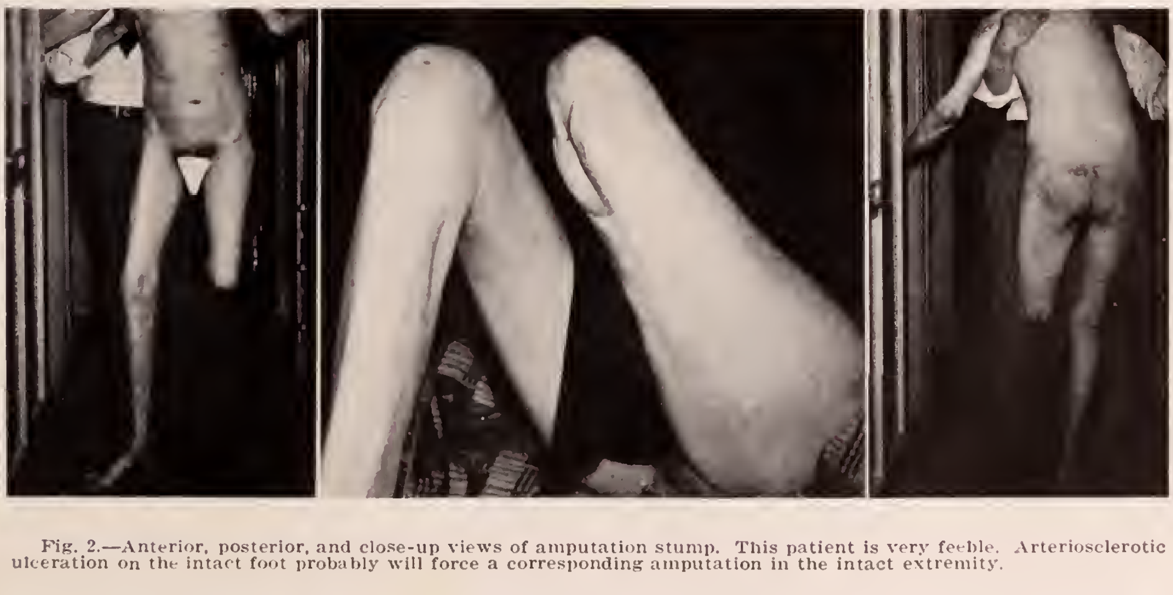

Fig. 2.—Anterior, posterior, and close-up views of amputation stump. This patient is very feeble. Arteriosclerotic ulceration on the intact foot probably will force a corresponding amputation in the intact extremity.

side to side since the essential structures have been divided. Deepening of the incision marking the posterior flap down to the gastrocnemius aponeurosis, and clearing from it the areolo-adipose débris, free the posterior flap. It is advantageous to leave the fibro-areolar tissue of the popliteal space in contact with the femur as far down as the level of the adductor tubercle in order that there be as little dead space as possible between the posterior flap and the femur.

The knee then is extended, and the incision marking the distal portion of the anterior flap is deepened through the capsule of the knee-joint down to the femoral condyles and the tibia, thereby severing the quadriceps tendon at its insertion into the tibial tuberosity. The anterior flap, containing the patella, is dissected upward, off the infrapatellar fat pad and drawn upward on the thigh until the superior synovial recesses of the subquadriceps space are seen. The patella is dissected from its sesamoid position in the quadriceps tendon, care being taken to preserve the longitudinally disposed tendon of the rectus femoris muscle which runs over it. Preservation of this tendon adds materially to the end-bearing capacity of the stump after the cut end of the femur is fitted into the socket from which the patella has been removed. The synovia on the anterior flap and over the femur proximal to the condyles is not excised. The femur now is sawed through its concellous portion about a centimeter proximal to the adductor tubercle. At this level the shaft of the femur has expanded to a size which approximately corresponds to the patellar socket in the quadriceps tendon. The cut end of the femur is rounded with a rasp until no sharp surfaces and no fringes of periosteum remain.

The two large flaps are now inspected for small bleeding points. These can be ascertained best by sluicing the surfaces of both flaps with large quantities of warm salt solution. This flushing has the additional advantage of washing away small soft tissue and bone débris. Many small bleeding points may require ligation after this procedure. Inspection of the body of the posterior flap shows no muscle fibers, but only areolo-adipose tissue and the cut ends of the hamstring tendons. These tendons already are retracted into their aponeurotic beds and are scarcely visible. The flaps now are allowed to fall together loosely. The only coapting suturing during the operation is in the form of not more than four to six skin-clips, placed at such intervals as to keep the flaps in fair apposition. When the skin edges are approximated, the aponeurotic edges also lie in contact; mere apposition is sufficient to produce firm union. None of the tendons or aponeuroses of the anterior flap are sutured to corresponding structures in the posterior flap. In this way no structure is under any tension, and the trauma and consequent pressure necroses resulting from suture of these deeper structures, therefore, cannot occur. The flaps appear exceedingly long, and immediately after they are fashioned may extend one inch or more beyond the bone end. To the surgeon accustomed to the routine type of lower third femur amputation, the flaps will appear excessively redundant and clumsy, and he will fear that a bulbous stump-end and large dead spaces will result. He will wonder, too, when he notes how wobbly the femur lies between the flaps, how the femur end will gain contact with the patellar socket and fuse there. During the early days of convalescence the reason for leaving these flaps under no tension appears. At the end of the second or third postoperative day, the hamstring muscles, severed only at their distal attachment, contract to the degree that the skin suture line lies posteriorly placed at about the level of the stump-end, and the femur is felt in the patellar fossa.

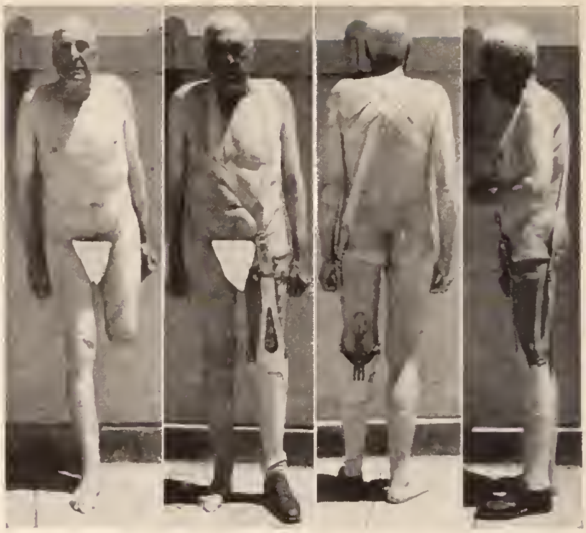

Fig. 3.—Views of an elderly patient wearing an end-bearing prosthesis.

POSTOPERATIVE CONVALESCENCE

After the operation the stump is wrapped snugly in a gauze roll and the patient is returned to bed. He is able to sit upright in bed in the evening of his operative day and can be placed in a wheelchair during the next day or two. Daily dressings are required because an abundant serosanguinous oozing between the skin edges may take place for several days, this in spite of the most meticulous hemostasis. The drainage gradually lessens. The absence of primary suturing other than that necessary for flap approximation minimizes the pocketing of fluid accumulation and allows all secretions to escape through the wide intervals between the skin-clips. Usually the major oozing stops in from one to three days. When this drainage has ceased, the skin edges between the clips or sutures placed at the time of operation are approximated carefully by additional skin-clips. These clips are applied readily without anesthesia. This procedure, which has been adopted only in our last cases, has resulted in complete union of the flap edges within a week. The time of convalescence has been decreased remarkably in this fashion. As convalescence progresses, the posterior flap retracts gradually until the suture line, now posterior in position, is well proximal to the bone end, occasionally a distance of one or more inches. When it is recalled that the suture line at the end of the operation is an inch or more distal to the bone end, it becomes apparent how extensive is the power of the intact hamstring muscles to retract the posterior flap. In a short time the femur is lodged securely in the patellar fossa, thus assuring great stability to the soft parts of the stump. There is excellent end-bearing because of the presence of the rectus femoris tendon, the elements of the prepatellar bursa, and of tough skin over the bone end. The patient is able to extend his stump powerfully, a requisite in any thigh amputation.

In my series healing has taken place in four weeks on the average. In our last three patients in whom the skin edges between the primary suture points were approximated secondarily by additional clips, healing was complete at the end of a week.

CONCLUSIONS

Mortality from thigh amputation will be decreased if the technique as outlined be followed meticulously. The factors which lower the mortality rate are: lessened shock from adequate control of blood supply and from section of muscles only in their tendinous insertions; diminished incidence of pneumonia from a lessened period of recumbency; decreased tendency to anaerobic or aerobic infection, because there are no structures under tension, this being the result of long flaps and no suturing; the serum produced in the wound has ready exit; and the lessened incidence of reamputation which in itself carries a considerable mortality. Reamputation has not been necessary in any of our cases, and should not be because of the adequacy of long anterior and posterior flaps.

Thus far fourteen amputations have been performed according to this method. The majority of these patients were over seventy years of age. One has died, a mortality of about 7 per cent. This man was eighty-four years of age, and died eleven days after his operation from a coincidental pneumonia. His amputation wound was fairly clean and had united partially. His amputation was the second in our series. At the time his operation was performed, we did not know that we could get our patients up practically immediately. It is possible that his pneumonia could have been averted by getting him into a wheelchair on his second postoperative day, the procedure we have adopted in all later cases. Thirteen out of these fourteen cases were amputated for arteriosclerotic or diabetic gangrene. One patient was amputated for intractable compound fracture near the knee.

The mortality statistics of thigh amputation vary widely. Much depends on the condition of the patients. The best of the larger series show a death rate of 15 per cent, while the series in the city hospitals and relief homes show much higher figures. Prior to the development of our operation, the mortality of thigh amputations on our service in the San Francisco Hospital exceeded 50 per cent.

450 Sutter Street.

DISCUSSION

Hugh Jones, M. D. (201 Medical Office Building, Los Angeles).—Doctor Callander's operation promises to be a valuable advance in the surgical care of gangrenous lower extremities. I am of the opinion that an extended series of cases will bear out the soundness of the anatomical reasons for this type of operation, first in regard to the circulation of flaps and also in the severing of muscles at their insertions rather than through fleshy bellies. There is a distinct advantage in gaining a longer stump, as well as an end-bearing stump. The avoidance of open paths for spread of anaerobic infection is another point worthy of emphasis.

This makes us realize that our knowledge of surgical anatomy is certainly incomplete, and that we should ever be critical in accepting without question our heritage of the classical operations.

⁂

E. W. Cleary, M. D. (490 Post Street ,San Francisco). Doctor Callander is to be congratulated upon developing this method of lower thigh amputation. An end-bearing stump is a very great advantage. For this reason the Gritti-Stokes amputation has been effective. The Gritti-Stokes technique is, however, sufficiently elaborate to carry with it relatively large limitations as to selection of suitable cases and, notwithstanding careful selection, a too high percentage of imperfect healings. Doctor Callander's operation commends itself because of simplicity and consequent wider range of applicability. His technique is about as near atraumatic as an amputation of the thigh could possibly be. Muscles are not cut, a large weight-bearing surface is preserved, the uncertainty contingent upon bony union of the retained patella has been cleverly avoided, and the use of ligatures and sutures has been brought to an irreducible minimum.

This amputation is, I believe, a significant improvement over all previously devised low-thigh amputations.

PATHOLOGIC FINDINGS AT THE PARS CARDIA OF THE STOMACH*

By Jacob Abowitz, M.D.
Los Angeles

Discussion *by Louie Felger, M. D., Los Angeles; H. H. Lissner, M. D., Los Angeles.*

THIS presentation aims to call attention to pathologic conditions in the pars cardia of the stomach and the relatively frequent changes occurring in the organs and structures adjacent to it. These changes, as observed fluoroscopically or radiographically, often give the first clue to pathologic conditions at the pars cardia, and may be of great aid in establishing a diagnosis.

CHANGES IN ADJACENT STRUCTURES

The Diaphragm.—Changes in position and excursion of the diaphragm often indicate pathology either above or below the diaphragm.

Cardiac End of the Esophagus.—The cardiac end of the esophagus, during deglutition, tapers down at the introitus of the stomach, and opens and closes intermittently, although a true sphincter does not exist there. When pathology is present this sphincteric action may be lost, and the cardiac end of the esophagus may be either gaping or contracted, depending on the nature of the lesion. The conical shape may become distorted and its lumen eccentrically displaced. These changes may be observed fluoroscopically with the aid of a barium mixture. Occasionally, when pathology is present, a speck of barium may be present at the cardiac end long after the barium meal has been ingested.

---

* From the department of roentgenology, Cedars of Lebanon Hospital, Los Angeles.

Read before the Radiology Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

The Gas Bubble (Magenblase).—There is almost always present a small amount of gas in the stomach. When the patient is in the upright position, the gas bubble rises to the pars cardia. In this position it is pear-shaped, point down. When the distal end of the gas bubble, on a fasting stomach or six hours after a barium meal, is replaced by a fluid level more than half an inch in width, it is an indication of gastric hypersecretion, or hyperacidity. This hypersecretion may be due to either reflex or local irritation.

A large gas bubble often indicates erophagia. Distortion of the shape or outline of the gas bubble may be produced by a new growth, extrinsic or intrinsic, of the pars cardia. A large gas bubble, by raising the left diaphragm, may produce cardiac symptoms. In diaphragmatic hernia the gas bubble is usually absent at the pars cardia.

Occasionally the pars cardia, especially its lesser curvature, is displaced laterally by an enlarged left lobe of the liver, while a distended splenic flexure displaces the greater curvature mesially.

PATHOLOGIC CONDITIONS FOUND IN THE PARS CARDIA

Carcinoma of the Pars Cardia.—In carcinoma of the pars cardia we invariably find the left diaphragm elevated, and its excursions decreased or absent. The gas bubble is distorted and encroached upon by a tumor mass, either on its left or right side, depending on whether the carcinoma is situated on the lesser or greater curvature. When the carcinoma invades the anterior or posterior wall, the tumor may be visualized through the gas bubble. As a rule, in carcinoma of the stomach there is hyposecretion, and no fluid level is present at the tip of the gas bubble. Normally, peristalsis is not well marked at the pars cardia; when carcinoma is present, peristalsis is entirely absent. Normally, the ingested barium mixture runs down the lesser curvature in a narrow stream; with carcinoma of the pars cardia this stream is deviated to the left, or divided into several irregular branches. A speck of barium often remains for a considerable time at the cardiac end of the esophagus. The filling defect in the stomach is best observed in the horizontal posture, when the pars cardia is completely filled with barium mixture. Carcinoma of the pars cardia of the stomach often invades the cardiac end of the esophagus, and vice versa when there is carcinoma of the cardiac end of the esophagus. A note of warning may here be sounded that the splenic flexure, when situated behind the pars cardia and when filled with intestinal contents, or distended with gas, produces a transitory filling defect in the barium-filled stomach simulating the filling defect of a carcinoma. The same is true when a large spleen is present. A reëxamination at a later date usually clears the question.

Diaphragmatic Hernia.—I shall not elaborate on this subject which became so popular of late through the lay press. I shall mention only a few points which may be of interest to the profession. In our routine gastro-intestinal examination of 1,100 patients, we have found diaphragmatic hernia in two per cent of the cases. Most of the herniae found are of the esophageal type; that is, the hernia enters the thoracic cavity through the esophageal hiatus in the diaphragm. A history of either a recent or an old injury was elicited from practically all of our patients, although the patients did not attribute their gastro-intestinal symptoms to that injury. Occasionally the isthmus connecting the hernia with the body of the stomach becomes ulcerated and bleeds, probably produced by the constriction of a small hernial opening. Three of our patients were so anemic that transfusions were indicated. In one of them a penetrating gastric ulcer was found at the isthmus of the hernia. Presuming that the small opening in the diaphragm produced the ulcer, an operation was performed to widen it, with subsequent marked improvement in the patient's condition. All the cases were discovered during fluoroscopic examination.

To demonstrate the hernia on the film we found a modified knee-chest position most satisfactory. Manual pressure on the barium-filled stomach on deep inspiration best demonstrates the condition. Occasionally, the horizontal position shows it better than the vertical. Three of our cases were recognized incidentally by observing the gas bubble behind the heart shadow. Two cases were discovered on genito-urinary films; the third, fluoroscopically, while administering a barium enema. I believe the visualization of the gas bubble behind the heart shadow is a valuable and unmistakable roentgenologic sign of a diaphragmatic hernia. To my knowledge, this observation has never been described before.

A Pouch at the Pars Cardia.—Not infrequently a pouch is present at the pars cardia on the lesser curvature below the esophageal hiatus. It is best visualized fluoroscopically in the right-oblique vertical position, when the stomach is only partly filled with the barium mixture. Then two fluid levels are seen: one in the pouch and one in the lower end of the stomach. This condition is variously described in medical literature as a "cascade stomach,'" a "shelving portion" of the stomach, or "cup and spill" deformity. The clinical significance of it is that it occasionally becomes inflamed or ulcerated; then the symptoms are the same as those of a gastric ulcer. The subjective symptoms are often a feeling of heaviness in the epigastric region after meals, probably due to the stasis of food in the pouch. One patient complains that she is awakened from her sleep by a drumming sound in the epigastric region. This sound is synchronous with the pulse and is produced by the heart apex beating against a gas-distended pouch.

Erophagia. — Erophagia is not an uncommon condition. It is often observed fluoroscopically. Occasionally it produces pressure on the heart from below. Recently one of our patients, a highly neurotic woman, suffered from periodic attacks of vomiting. Fluoroscopically, we noticed that she subconsciously swallowed so much air that there was very little room left in the stomach for food, and eructation of the gas produced vomiting.

IN CONCLUSION

In conclusion, may I say that, although the pars cardia is considered the silent area of the stomach, and only about five per cent of pathology occurs there as compared with the rest of the stomach, nevertheless this presentation indicates that the extra effort of a thorough and careful examination of this region is often well compensated.

Cedars of Lebanon Hospital.

DISCUSSION

Louie Felger, M. D. (1930 Wilshire Boulevard, Los Angeles).—Lesions of the pars cardia of the stomach are responsible for many obscure and atypical symptoms referable to the lower part of the thorax and the upper part of the abdomen. The pars cardia is a relatively silent area, and there are no symptoms which are diagnostic of pathology in this location.

In diaphragmatic hernia the symptoms are due to impairment of respiration and circulation, or to disturbed function of the herniated abdominal organs. The increase in the recognition of diaphragmatic hernia is entirely due to marked advances in roentgenologic study. A survey of these cases shows that the diagnosis is rarely suspected by the clinician, these cases being diagnosed as gall-bladder disease, peptic ulcer, carcinoma of the stomach, intestinal obstruction, and heart disease. Three cases were hospitalized with hemoglobins of 15, 17, and 19 per cent, respectively, and regarded as hopeless carcinomas of the stomach. However, x-rays revealed diaphragmatic herniae with large ulcers in the herniated portion of the stomach.

It has been recommended that diaphragmatic herniae be looked for when the findings at surgery do not seem sufficient for intra-abdominal complaints. Many operations upon the gall-bladder, stomach, and appendix have been performed because of unrecognized diaphragmatic herniae.

⁂

H. H. Lissner, M. D. (1908 Wilshire Boulevard, Los Angeles).—The numerous diagnostic points brought out by Doctor Abowitz in his article open up a new field of thought not only from the standpoint of x-ray diagnosis, but also because they merit serious consideration from the clinician as an aid in clearing up certain problems which, under the older methods, have remained obscure.

It has been the custom of the clinician to refer his patients to the roentgenologist for certain studies and to accept the latter's report as *prima facie* evidence, for or against a given condition, without checking over the pictures together or correlating the x-ray with the clinical findings. Usually if the x-ray does not agree with the clinical diagnosis, it is the latter which is discarded and the former is accepted irrespective of the clinical evidence in its favor. The fixing of the mind upon a definite organ to be studied, and the centering of thought upon a certain part of that organ, and not considering it as a whole, have caused many errors to creep in between the x-ray findings and the clinical diagnosis of a disease. This error is best exemplified in the study of the stomach. If the internist asks for a gastro-intestinal series, the pylorus of the stomach is the part usually studied and we are shown a series of photographs taken at various time intervals representing the function of the pylorus. If these photographs are reported as being negative, the internist begins to look about for another peg upon which to hang his clinical diagnosis. However, by looking at the organ as a whole we have been able to develop a relationship between the roentgenological and the clinical aspect of the patient's discomfort, which is just as essential to the patient's welfare as is good teamwork between the surgeon and his trained assistant. The studies of the cardiac end of the esophagus, and of the pars cardia, under this scheme of coöperation have resulted in picking up several cases of carcinoma of the stomach in this region which had been overlooked in a number of previous x-ray studies. The diagnostic points outlined by the author are invaluable aids to a better reading of the x-ray studies of the stomach, and should bring to the fore the fact that stomach symptoms are caused by lesions in this organ in its so-called "silent area," even though the esophagus or the pylorus are not primarily involved.

Another very important point brought out by Doctor Abowitz is the presence of an air bubble or shadow behind the heart in diaphragmatic hernia. If the hernia is large, the usual distortion of the magen blase is seen to the left of the heart shadow; but in some instances where the hernia is small the shadow generally will cause a lighting up of the usual cardiac silhouette. Here again I wish to emphasize that the fixing of the mind focus upon the heart itself and the elimination of the rest of the chest content from the mental picture.

Cases of diaphragmatic hernia have been suspected upon attempting to explain this shadow, and upon further barium studies have been proved to be hernia. The cardiac symptoms produced by this lesion vary with the patient and the size of the hernia. Dyspnea, after a big meal, is an outstanding symptom, and is dependent upon the size of the hernia and the amount of cardiac displacement. Precordial pain is not a prominent symptom.

The pouch of the pars cardia is a very interesting condition and one that at times is the cause of great concern to the patient, because of the drumming sound which frequently accompanies it. As might be suspected, the sound varies from that of a drumming character to a more musical or kettle-drum sound, or even at times has a bell tone. It can be controlled by changing the position of the patient from the left to the right side.

The diagnostic data brought out in Doctor Abowitz's paper will, I hope, stimulate a closer liaison between the roentgenologist and the clinician, and will open our eyes to the rest of the x-ray pictures, besides the study of the particular organ for which it was taken.

⁂

Doctor Abowitz (Closing).—Since the presentation of the above paper, I have observed the following case:

In examining a chest film, I noticed a somewhat opaque spherical shadow in the region of the heart, measuring about three inches in diameter. Several diagnostic possibilities presented themselves: (1) aneurysm of the thoracic aorta; (2) a mediastinal new growth; (3) a mediastinal abscess; (4) diaphragmatic hernia; or (5) a dilated esophagus. The clinical signs and symptoms offered no help in diagnosis. The fluoroscopic examination in the left oblique vertical position showed the left border of the spherical shadow protruding beyond the left side of the heart, and not pulsating. The fluoroscopic observation after the administration of a barium mixture revealed a diaphragmatic hernia with the pars cardia of the stomach above the diaphragm. The walls of the herniated protrusion were thickened and adherent in the posterior mediastinum. The esophagus, which was normal in shape, stopped short just above the diaphragm.

TREATMENT OF EXOPHTHALMIC GOITER*

By H. Ross Magee, M.D.
Los Angeles

Discussion *by John C. Ruddock, M.D., Los Angeles; A. B. Cooke, M.D., Los Angeles.*

FOR the control of exophthalmic goiter we have two therapeutic weapons of proved value: (1) the administration of iodin, and (2) resection of the thyroid gland. Partial destruction of the thyroid gland by roentgen rays has also been found to be of some value, although its beneficial results often prove to be only temporary. J. H. Means and his associates [2,3] at the Massachusetts General Hospital have reported favorable results in a considerable number of cases in which patients were treated by roentgen rays.

---

* Read before Santa Monica Branch of Los Angeles County Medical Society, Santa Monica, California, April 9, 1935.

The popularization, since 1922, of preoperative treatment with iodin has resulted in a reduction of the surgical mortality to less than one per cent. Physician and patient no longer regard thyroidectomy as a dangerous operation, to be undertaken only when conservative measures, such as roentgen treatments, have failed. The evaluation of any method of treating exophthalmic goiter is possible only if one is careful to keep in mind that the natural course of the disease, when untreated, is characterized by exacerbations and remissions, and there is a tendency for it to cease spontaneously after a course varying in length from a few months to more than twenty years.

ETIOLOGY

Although the primary cause of exophthalmic goiter is not known, the available evidence indicates an abnormal, intensive stimulation, from some unknown source, of the entire thyroid gland. This stimulation results in diffuse hypertrophy of the thyroid epithelium. In practically all cases, excessive quantities of thyroxin are produced and are delivered to the tissues. With this intensive stimulation of the thyroid gland, the normal supply of iodin may prove inadequate for its requirements, so that at least a part of the secretion produced and delivered to the tissues may be abnormal in quality, and possibly be an imperfect form of thyroxin. This hypothesis, developed by C. H. Mayo and H. S. Plummer, affords the most satisfactory explanation of the clinical phenomena of exophthalmic goiter, and of the effect of iodin in this disease.

CHARACTERISTIC FEATURES OF EXOPHTHALMIC GOITER

The chief and characteristic features of exophthalmic goiter, which distinguish it from adenomatous goiter with hyperthyroidism, are the peculiar nervousness and irritability suggestive of cerebral intoxication, the useless purposeful movements, the exophthalmos, stare, and other ocular signs, and the gastro-intestinal crises with vomiting and diarrhea. It is probable that all of these characteristic phenomena of exophthalmic goiter are attributable to an abnormal thyroid secretion, as they cannot be regarded as due to pure hyperthyroidism. The degree of intensity of these symptoms is not proportional to the degree of elevation of the basal metabolic rate. Progressive exophthalmos may occur when the basal metabolic rate is zero, or is as low as minus 20 per cent. A patient presenting marked evidence of cerebral intoxication, with a basal metabolic rate of plus 20 per cent, may be precipitated into a severe crisis by an infection or by an operation. On the contrary, a patient with a basal metabolic rate of plus 90 per cent may show little or no evidence of cerebral intoxication, and may undergo thyroidectomy with practically no risk of a postoperative crisis.

Although accurate statistics are not available, it has been observed that the characteristic features of exophthalmic goiter are more pronounced in the Mississippi Valley basin and Great Lakes region, where the iodin content of soil, water, and food is less than in the coastal regions. The gastro-intestinal crisis is seen much oftener in the Northwest than in New England. This and other observations led H. S. Plummer, in 1922, to administer compound solution of iodin (Lugol's solution) to a series of patients with exophthalmic goiter. The beneficial results were so striking that iodin is now used routinely in the treatment of the disease. As had been anticipated from theoretical considerations, the administration of iodin was found to relieve all the characteristic symptoms of exophthalmic goiter which differentiate it from adenomatous goiter with hyperthyroidism. Patients in crisis stopped vomiting within a few hours, often after the first dose of iodin. Exophthalmos was arrested. The characteristic psychic status was abolished, and the useless purposeful movements ceased. The degree of clinical improvement was found to depend on the relative predominance of symptoms referable to the abnormal thyroid agent. The beneficial results in cases in which patients had a high degree of cerebral intoxication or were in a gastro-intestinal crisis were the most striking. In this group there was usually a proportionately large drop in the basal metabolic rate. With patients who had exophthalmic goiter of long standing and a basal metabolic rate often of greater than plus 75 per cent, but who had little evidence of the characteristic cerebral intoxication of the disease, improvement on administration of iodin was much less marked. Often only a very slight drop, or no drop at all, in the basal metabolic rate occurred. It is probable that in this group of cases the thyroid gland had been accustomed, ever a period of years, to utilize small quantities of iodin and yet produce a relatively high proportion of normal thyroxin. Such cases may perhaps be said to be "iodin-fast," or resistant to iodin. The probable explanation is that the iodin supply of the thyroid gland had been sufficient for its needs, and an additional supply was not utilized.

Patients with exophthalmic goiter who have been given iodin for some time may later have an increase in the basal metabolic rate and some intensification of symptoms. This should be interpreted as an exacerbation consistent with the natural course of the disease and not as one due to the administration of iodin. Such an exacerbation is almost always more intense if the administration of iodin is discontinued.

PREOPERATIVE TREATMENT WITH IODIN

Preoperative treatment with iodin has now become standard in all surgical clinics, although the form of administration and the dosage still vary to some extent. As little as one minim of Lugol's solution daily may be sufficient in some cases to produce the maximal improvement possible. In most cases it seems advisable to give 10 minims of Lugol's solution three times daily, and in a few cases larger doses will produce more benefit. For patients in crisis it is necessary to give 50 to 100 minims of Lugol's solution daily for the first few days.

The maximal drop in the basal metabolic rate most often occurs about the seventh to the tenth day after the administration of iodin is begun. In some cases the maximal drop may occur about the end of the second week, and occasionally even later.

In a few cases the administration of iodin results in a complete remission, with control of all the symptoms and a return of the basal metabolic rate to normal. Discontinuance of iodin in such cases is usually followed by a return of the symptoms within two weeks. If administration of iodin is continued, the remission occasionally remains complete. After a variable period of time it may even be possible to discontinue the administration of iodin without recurrence of symptoms. This program entails a long period of observation in order to be certain of continuous and complete control of the disease, and in most cases it is not a practicable one. Moreover, after a period of weeks and months of complete control with iodin, an exacerbation may occur which is not fully controllable by iodin alone, and thyroidectomy may become necessary. The safest and most economical program is, therefore, to carry out partial thyroidectomy in these cases, even though the administration of iodin has resulted in complete remission.

PARTIAL THYROIDECTOMY

Partial thyroidectomy may safely be performed in milder cases after seven to ten days of preoperative treatment with iodin. In more severe cases it is best to delay operation for three or four weeks, or even longer, to allow the patient to recuperate. Especially is this necessary when there has been a marked loss of strength and weight or a recent acute infection. Most patients may be allowed to be ambulatory while they are being prepared for thyroidectomy. Patients who are extremely weak, those in crisis, and those who have a complicating acute infection, cardiac decompensation, or other visceral degenerative changes, must be kept in bed during the first part of the preoperative treatment. However, it is very important that they be up and about for at least a few days prior to operation in order to allow them to regain their strength. Patients who are too weak to walk about the room are not yet ready for operation.

CONGESTIVE HEART FAILURE

Patients with congestive heart failure will often rid themselves of as much as ten to twenty pounds (4.5 to 9 kilograms) of edema fluid on a simple program of rest in bed and Lugol's solution. For others it is necessary to use one of the intravenous diuretics, such as salyrgan. By restricting the intake of fluid to from 1,000 to 1,500 cubic centimeters daily, with oral administration of six grams of ammonium nitrate daily and one to two cubic centimeters of salyrgan intravenously every three or four days, patients with an extreme degree of anascara usually become fluid-free within two weeks. Digitalis in moderate doses is occasionally used to reëstablish cardiac compensation. However, patients with hyperthyroidism seem to be especially susceptible to the toxic effects of digitalis. The drug should be used more cautiously and in smaller doses than in cardiac decompensation due to other causes. It is also important to discontinue the administration of digitalis a few days prior to thyroidectomy. Auricular fibrillation often is replaced by a normal sinus rhythm as cardiac compensation is reëstablished. However, persistence of auricular fibrillation does not *per se* add a great deal to the risk of operation.

It is very important to have patients with exophthalmic goiter follow a diet high in calories. As much as 5,000 calories daily may be required to check the loss of weight due to the greatly increased total metabolism. Even in the presence of diabetes mellitus, it is necessary to give a diet high in calories with enough insulin to control the blood sugar.

THYROID RESECTION

Thyroid resection was at first usually limited to excision of the larger lobe, leaving the second lobe to be resected later if it enlarged subsequently. Standard thyroidectomy now consists of resection of both lateral lobes with removal of the isthmus of the gland. Preservation of the posterior part of each lobe, comprising a sixth to a half of the gland, insures sufficient secreting thyroid tissue to prevent postoperative myxedema. Persistence or recurrence of the symptoms of exophthalmic goiter is much less frequent since the introduction of this type of bilateral resection. Since, also, the introduction of preoperative treatment with iodin, patients come to operation in a much better condition to withstand thyroidectomy. The surgeon, therefore, feels able to do a more complete resection than would have been possible when even a slight prolongation of the operative procedure was likely to cause the death of the patient.

Prolonged inhalation anesthesia is very harmful to the patient with hyperthyroidism. Local anesthesia, using procain hydrochlorid, supplemented by nitrous oxid and oxygen, is the most satisfactory method. Sodium amytal or avertin anesthesia does not allow the surgeon to test the function of the vocal cords by having the patient speak or cough.

TECHNICAL ERRORS

The most frequent technical errors which the operator seeks to avoid are injury to the recurrent laryngeal nerve and postoperative hemorrhage. If hemostasis is difficult, this may often be achieved by ligation of one or both inferior thyroid arteries at a point proximal to their entrance to the gland. Occasionally, the wound must be packed and left open. Injury to the nerve is best avoided, according to Pemberton, by preserving the posterior, mesial portion of each lateral lobe and avoiding exposure of the lateral wall of the trachea. If the voice shows that the nerve has been injured, the immediate removal of a constricting suture will be followed by a return of normal function in six to ten weeks.

MULTIPLE STAGE OPERATIONS

Prior to the advent of preoperative treatment with iodin, the fear of a severe postoperative hyperthyroid crisis often led to the employment of the multiple stage operations. Ligation of one or more of the chief thyroid vessels was often done in the hope of reducing the vascularity of the gland, thus causing it partially to atrophy. After one or more ligations, the patient was often able to undergo subtotal thyroid resection with much less risk of postoperative crisis than if primary thyroidectomy had been done. Similarly, lobectomy—the resection of one lobe only, which involved but half the surgical trauma and half the chances of technical error as compared with resection of both lobes—was found to be followed by such a marked improvement in the condition of the patient that a second lobectomy could be done a few weeks later with much greater safety.

Since preoperative treatment with iodin, the need for multiple operations has greatly decreased. Ligation is seldom employed, as it rarely produces any more improvement in the patient's condition than could be produced by the administration of iodin. In the small group of cases in which the condition is of several years' duration, and the thyroid gland is large and hard and the basal metabolic rate is high, removal of one lobe at a time involves much less danger than removal of both lobes at once.

POSTOPERATIVE COMPLICATIONS

One of the most frequent postoperative complications is respiratory obstruction, due to injury of the recurrent nerve, tracheal pressure, or excessive tracheal mucus. Respiratory obstruction may lead to pulmonary edema, anoxemia, cyanosis, and bronchial pneumonia. Oxygen is of very great value for these complications, and its use should be begun as early as possible. It is advisable to maintain a concentration of 50 per cent oxygen in the tent or oxygen chamber. Acute hyperthyroid reactions are very uncommon since the advent of preoperative treatment with iodin. It is essential to continue the administration of iodin during the postoperative period. Small doses of iodin should also be given, at least periodically, for at least one year after thyroidectomy. This program will in many cases prevent recurrence of exophthalmic goiter.

IN CONCLUSION

While the majority of patients are completely and permanently relieved by iodin followed by partial thyroidectomy, a definite though small number will have recurrence of the syndrome later. Although this is more common when sufficient thyroid tissue has not been removed, recurrences may result even when a very small amount of thyroid tissue is preserved. It seems probable that such recurrences take place in a group of cases in which thyroid stimulation has been more intense and prolonged than in the average case. Recurrences are usually mild and controllable by iodin alone. If the thyroid remnant subsequently enlarges, the symptoms are less likely to be controlled by iodin alone, and further resection of the gland must be carried out.

DISCUSSION

John C. Ruddock, M. D. (1930 Wilshire Boulevard, Los Angeles).—Doctor Magee's paper presents very clearly and forcibly the problem of the hyperthyroid patient. Doctor Magee brings out the complex picture of the disturbed physiology, namely, the utilization of iodin, the production of thyroxin and the storing up of colloid material. The proper functioning of the gland is intimately associated with all three of these factors, as each one bears a direct relationship with the other. The physiology is disturbed from some cause and, naturally, all manifestations which present themselves are the result of a disturbed function of the gland.

Because of knowledge gained, experimentally and clinically, of the function and physiology of the thyroid gland, we are able to restore a dysfunction to normal function, by evaluating the disturbing elements causing the changes in metabolism. This is done by increasing utilizable iodin, thereby increasing colloid and decreasing circulating thyroxin; or, vice versa, increasing circulating thyroxin, which results in decreasing colloid and utilizable iodin. There are many gradations, however, between these two simple extremes, and the problem may be very complex.

The influence of the thyroid is far-reaching, and its effect on the human organism is such that stabilization is essential, if any radical procedure is contemplated.

Experience has shown clearly that medical management of the hyperthyroid state is not sufficient to maintain a normal status, and again surgery is not the answer. However, surgery offers more at the present time than any other type of therapy. The weak link in the surgical treatment is that the surgeon must make a judgment at the time of operation as to the amount of tissue to be removed, in order that the physiologic function of the gland will be returned to normal. It is indeed a lucky man who removes *exactly the right amount of tissue* in every case.

I would take issue with Doctor Magee as regards digitalis therapy in cases of hyperthyroidism. Digitalis should not be used except for cardiac decompensation, and then should be given exactly and in the same amount as would be given any other decompensated heart. Tachycardia or auricular fibrillation without decompensation are not indications for digitalis. Digitalis in moderate dosage will give disappointing results in restoring compensation, and should be used in dosage sufficient to get full physiologic action.

Doctor Magee has brought out the problem of therapy of hyperthyroidism. Shall it be medical? Shall it be surgical? Shall it be by roentgen ray? Shall it be by various combinations of the three? Or shall we admit that there is yet much knowledge to be gained, and much experimental research to be done in order to solve the problem of therapy for the hyperthyroid state?

⁂

A. B. Cooke, M. D. (2007 Wilshire Boulevard, Los Angeles).—The very full discussion Doctor Magee gives to the question of iodin in his paper on the treatment of exophthalmic goiter is perhaps its outstanding feature. While certain of the views expressed are controversial, in the main he presents the accepted teaching on the subject.

I believe it is wise always when mentioning iodin as a treatment of exophthalmic goiter to use the qualifying term "preparatory," lest the idea be conveyed that it is a curative remedy for the malady. Much harm is being done by some physicians in the indiscriminate and prolonged use of the agent—direct and immediate harm occasionally, but more often in its long-continued use for the purpose and with the promise of cure. I very rarely see a case of thyroid disease of any kind in which this remedy has not been used, and, in the sense referred to, *abused*.

The importance of exophthalmos as a diagnostic symptom is sometimes overemphasized. If present, it is practically pathognomonic when associated with other symptoms.

But we must remember that it occurs in only some 50 or 60 per cent of cases, and that it may occur entirely independent of thyroid disease.

Too much reliance should not be placed on the value of basal metabolism readings. Like other laboratory findings they are to be interpreted as corroborative and confirmatory aids in reaching a correct diagnosis, and then only when taken under proper conditions with an apparatus known to be accurate and by a technician known to be fully competent.

The statement is made that since the advent of the iodin preparatory treatment the surgical mortality has been reduced to less than one per cent. This statement might easily prove misleading. Such results are obtained when the surgery is done by experienced operators. But the mortality rate is much higher in the hands of the inexperienced. Here 10 per cent would probably be a more correct figure.

Doctor Magee's address is a good presentation of the management of exophthalmic goiter, embodying the best that is known on the subject at the present time.

ATHLETIC INJURIES*

By Packard Thurber, M.D.
Los Angeles

Discussion *by Harold H. Hitchcock, M.D., Oakland; George O. Berg, M.D., Los Angeles; E. F. Roth, M.D., Palo Alto.*

GENERALLY speaking, athletic injuries differ little from injuries caused by other means. However, there are certain conditions that are at least common, if not peculiar, to athletic endeavor, and therefore the prevention and treatment of these injuries cause us to digress from the usual methods of treatment in certain instances.

STAFF ORGANIZATION

Not so many years ago, most injuries, at least on the field of competition, were given first aid by "trainers" or "rubbers," but I believe that at present practically all of the universities maintain a well-organized medical department, with a regularly licensed physician in charge. At the University of Southern California the Athletic Medical Department adjoins the Varsity dressing rooms, and is comprised of minor surgery, x-ray, hydrotherapy, massage, and examination rooms. The personnel consists of the medical director, two assistant surgeons, dentists, masseurs, and historian.

All of the above are on active service during the athletic year and, in addition, we have a consulting staff of representative men in their respective specialties.

EXAMINATIONS OF CANDIDATES

At the beginning of the athletic season a complete physical examination is given all candidates, including complete dental x-rays and mouth charts. Helmets, shoulder-pads, hip-pads, shoes, and other equipment are checked to forestall avoidable injuries. Team members are then advised that, while the University does not assume responsibility for injuries resulting from athletic competition, they offer the services of their medical department; but if the athlete so desires he has the privilege of securing other medical attention at his own expense. In any event, an injured athlete must be examined and passed as fit for further competition by the University medical staff. All minors are instructed to obtain operative permits from their parents or guardian, and these are filed for use in case of emergency.

The director of athletics sends a program of events to the medical director's office each Monday morning and arrangements are then made for one of the staff doctors to be in attendance at all contests wherein the University is host. Consequently, injured athletes are extended immediate treatment by a registered, licensed physician.

FITNESS TO ENGAGE IN SPORTS

In our organization the medical director determines the fitness of an athlete to continue competition, and we are, therefore, confronted at times with rather serious responsibility because many of the athletes are minors, and during the most athletic contests we are restricted to two or three minutes to diagnose, treat and decide whether or not the patient shall be withdrawn from the contest. We are aided, however, in this respect by the fact that we are familiar with the physical condition, reactions, temperament and peculiarities of the individuals, since they are under our direct observation practically every day during each athletic season. Furthermore, at times we use a few fundamental rapid tests on the field, such as the Rhomberg, eye-reflexes, et cetera, in concussion cases, and determine their mental equilibrium by asking questions pertinent to the particular athletic endeavor in which they are engaged at the time of injury.

It is somewhat superfluous to remind you that the members of these athletic teams are all anxious to reach the top and remain there; and while we dislike to disqualify them, nevertheless we recommend substitution where an injury creates a special hazard. We believe it fair to assume that the athletes and their parents are aware of the possibility of injury under ordinary circumstances, but where a condition materially increases the hazard we acquaint the parent with our findings and abide by their decision. In rare cases, of course, where the issue is clear the medical director recommends absolute retirement.

A few words concerning another phase of the subject, wherein it differs from private practice, may be said in connection with the importance of keeping the athletes in active competition. You all know that track, basketball, baseball, football, and the other athletic seasons are of relatively short duration, and that, in many cases, with special protective apparatus and the consent of the parents, we permit the player to continue; whereas in private practice we would probably restrict a patient's activity. Necessarily, these special splints that we use must be of light weight, small proportion, and conform to certain rules and regulations, designed to protect the other players from injury.

TYPES OF INJURIES

Obviously, our most common injuries are acute sprains, such as the acromioclavicular joint (shoulder joint); subacute sprains, following repeated strains, such as attachments of pronator teres, flexor and extensor groups at the elbow (golf and tennis elbow); strains of the anterior tibial group attachments (shin splints); severe, deep muscle contusion with hemorrhage (Charley horse); contusion with avulsion muscle attachments pelvic rim (hip point); abrasions (floor burns); bursitis, tenosynovitis, dislocated finger joints, knee cartilage and ligament injuries, and, early in the season, blebs, intertrigo (jock strap itch), dermatomycosis (athlete's foot), etc. The less common and more severe types are the concussions (brain and chest), fractures, major dislocations (shoulder, elbow), etc.

---

* Read before the Industrial Medicine and Surgery Section of the California Medical Association at the sixty-fourth annual session, Yosemite National Park, May 13-16, 1935.

TREATMENT

With regard to treatment, while there are many different types and methods, we feel that fundamentally our most valuable assets are:

1. *Anatomical Relocation of Injured Tissues.*—In this connection I more particularly refer to sprains, torn ligaments, and strains of muscular attachment about joints, because in these conditions the essential pathology consists of a small area of effusion at the point of trauma, and the pain is due to tension or pressure on this effusion. Whether the repair of damage is by first intention or becomes a subacute or chronic condition, depends upon the treatment instituted. If the effusion is absorbed and the torn ends of tissues approximated and maintained in their normal position for a sufficient period of time, prompt and complete repair will ensue. "Sufficient time" is ten days to two weeks, we believe, except in the very severe cases. Conversely, if the damaged area is subjected to repeated assault by muscular effort or other movement, stretching and tearing of the newly formed repair tissue take place and create a subacute or chronic process by producing a small plexus of fibrous tissue which, in turn, impedes circulation and, therefore, the complete absorption of the effusion.

2. *Heat and Massage.*—These are used according to accepted methods.

3. *Supportive Treatment.*—Under this heading are grouped compression bandages, elastic bandages, taping over adhesive, and sponge rubber pads, etc., and these assume an important rôle in treatment. The problem of "athlete's foot" and allied skin conditions have been adequately controlled for the past several years by water-cooled quartz lamps and thorough removal of moisture between the toes, following the shower.

A word about knee cartilages: My observations, while operating on these joints, lead me to the conclusion that forced manipulation of a locked knee is seldom justified. In those instances where a knee will not unlock within two or three days with relaxation, our operative findings usually indicate the futility of forced manipulation, in so far as any permanent relief is concerned.

CONCLUSIONS

Considering the opportunity for physical damage, we believe that the standard protective equipment, including special splints and apparatus, is satisfactory; but, of course, all injuries cannot be prevented.

Good physical condition and consummate effort tend to forestall injury. For example, many injuries in football practice occur in so-called dummy scrimmage, where maximum physical effort is not exerted.

It is of prime importance to allow acute injuries "sufficient time" to heal by primary intention.

Manipulation of injured members should be avoided until a definite diagnosis has been made.

Athletes with known physical ailments, creating a serious extra hazard to injury, should be disqualified.

The National Collegiate Athletic Association, through its proper committees, has done much in the way of rule changes to eliminate injuries.

417 South Hill Street.

DISCUSSION

Harold H. Hitchcock, M. D. (1624 Franklin Street, Oakland).—The method of handling injuries among athletes does not vary much in our American colleges, since the gate receipts from football has put the average college into big business.

The diagnosis and outline for treatment, as well as the decision as to when the man shall return to competition, has been taken away from the coach and trainer and put into the hands of trained medical men with a corps of consulting specialists. It is true that coach and trainer still attempt to exert their influence by calling men yellow at times who claim to have been injured, or try to bring undue influence on the athletic physician to permit an excellent player to return to competition before he should.

It is our feeling that the cheers of the multitudes in the bleechers soon die out; that too many athletes are better endowed with physique than brains, and if this physique is ruined because of permitting them to compete while injured in college, that an irreparable damage has been done, both to the student and to the sport in which he competes.

In dealing with athletic injuries in our American colleges, most of the patients are between eighteen and twenty-four years of age and are excellent physical specimens. There are certain fairly common congenital and developmental conditions which predispose some men to back injuries such as prespondylolisthesis and congenital anomalies of the low back and juvenile kyphosis with Schnorl's changes.

We feel that all injuries should have good x-rays when there is any chance of bone or joint injury. This practice has shown us many fractured carpal scaphoids that would have been missed and called sprained wrists, many fractured laminae in the spine, many congenital anomalies of the spine, which are a factor in making their backs more vulnerable.

Injuries to the lateral ligaments in the knee that are severe enough to permit lateral instability are treated by immediate open operation and repair. Knees that fill quickly with fluid after injury are aspirated, as they usually contain blood. We do not aspirate if we feel the fluid is a simple effusion in the knee. Exercises for the quadriceps muscles are begun at once. The patient is not permitted to return to competition until this muscle has returned to normal. Injuries to the semilunar cartilage and fat pads are common. If a cartilage is injured it is removed, otherwise the knee does not return to normal. The only place for manipulation in the treatment of knee-cartilage injuries is for temporary relief.

Muscle injuries in track athletes sometimes appear trivial, but result in grave consequences if they are permitted to run. I have seen spiral fractures of the tibia and fibula occur from the calf muscle contracting. Michigan's two-mile runner had had a sore calf for two weeks before competing against California this year. In that race the calf contracted, he heard and felt his leg bones break, and then fell and pushed the tibia through the skin to compound the fracture.

I have twice seen the humerus broken in throwing a ball by a player with a sore arm.

We feel that all broken necks should be prevented from further athletic competition.

In football we find more injuries occur in a poorly conditioned, a fatigued or dazed man, or in a team that is demoralized and receiving a severe beating. These individuals are slowing up, not coördinating, and are apt to be injured.

If college athletics are to continue, especially football, those intrusted with the care of injured athletes must have the courage to keep any injured man from competition until he has completely recovered and is not suffering additional risk by virtue of his recent injury.

*

George O. Berg, M. D. (6253 Hollywood Boulevard, Los Angeles).—In athletics we have preventive medicine as well as curative. We use all of the known principles in both fields, and we augment the first with suitable protections for all injuries.

We deal with men in a remarkable state of health. They recover rapidly, and most of them are fired with the ambition to compete. Many will hide injuries, and a small minority will magnify injuries. We are seeing a rapid evolution and change in the methods of diagnosis and care of injuries. The old-time "punch drunk" type of trainer is being replaced by men of training and sympathetic outlook.

In general, I agree with Doctor Thurber's comments on types and treatment of injury. Let me say that the common injury, known as charleyhorse, was studied scientifically by me at the University of Wisconsin ten years ago. By pathologic material from dogs I proved that the various stages such an injury goes through are:

1. Hemorrhage and serous swelling between muscle bundles, occurring chiefly close to the bone.
2. Subperiosteal hemorrhage.
3. Excavation of necrotic muscle tissue by polymorphonuclear leukocytes.
4. The formation of fibrin.
5. Change of this to the fibroblast.
6. Metamorphosis of the fibroblast to connective tissue cells.
7. The development of the connective tissue cell as a bridge.
8. The burrowing through an area of scar tissue by muscle-buds springing from uninjured muscle tissue with burrowing buds loaded with juvenile types of cellular nuclei in a manner similar to the function of the osteoblast.
9. Union of these buds and restoration of tissue, as well as function, provided we have not insulted nature by reinjury.

We use all standard methods of physiotherapy in treatment.

At this time I desire to warn this group against acceptance of unsupported statements by unscrupulous manufacturers that radiotherapy apparatus will not burn. Such a statement is untrue. We have had the misfortune of having a severe burn occur while treatment was being given under the direction of the demonstrator employed by one of these companies.

I have been successful in getting several cases of dislocated semilunar cartilages to heal with a reliable knee-joint resulting. This has been possible through immediate reduction of the dislocation under anesthesia and immediate application of a plaster cast and bed rest for two weeks following by appropriate physiotherapy.

*

E. F. Roth, M.D. (300 Homer Avenue, Palo Alto).—I find the set-up for the care of athletic injuries at the University of Southern California is much the same, with individual variations, as the set-up at Stanford University.

The public and the profession have been under the impression that athletic injuries as a whole have been handled in a haphazard manner, principally by trainers and rubbers. This article, therefore, gives some general idea of the facts in connection with athletic injuries as handled by most of the large universities on the Coast.

The treatments used coincide, as a rule, with those of any orthopedic surgeon, with the advantage of seeing the injuries immediately after their occurrence. Thus we are able to apply immediate control measures to hemorrhage and secondary trauma to the damaged tissues; and this, with the youth and enthusiasm of the patients, helps us to complete many rapid recoveries.

MORTALITY LESSONS IN A SERIES OF 4,029 GYNECOLOGIC OPERATIONS[*][†]

By Harold K. Marshall, M.D.
and
Robert H. Thompson, M.D.
Glendale

Discussion *by L. A. Emge, M. D., San Francisco.*

The value of mortality and morbidity studies is incontrovertible. The periodic audit establishes standards for comparison. Its advantages are many. For the patient, mortalities are reduced. For the surgeon, his illusions are disproved, his surgical conscience aroused and he is stimulated to greater efforts and to the correction of faults. Regular, honest auditing of our surgical results is a basic cornerstone upon which progress rests.

CLINICAL MATERIAL REVIEW: PERIOD FROM JULY 1, 1928 TO JULY 1, 1934, AT LOS ANGELES COUNTY HOSPITAL

In this paper is presented a review of the deaths on the gynecological service of the Los Angeles County Hospital, covering a period of six years, from July 1, 1928 to July 1, 1934. An analytical study of each case has been made with reference to preoperative status, type of operative procedure and postoperative course.

During the six-year period there were 7,812 patients admitted on the gynecological service, with a total of 183 deaths, an incidence of 2.3 per cent. A total of 3,783 patients were discharged without operation, leaving 4,029 (51.6 per cent) that underwent some type of primary operative procedure. There were 121 deaths in the operated group—a gross operative mortality of 3.0 per cent. Three thousand five hundred and five, or 87 per cent, of these were laparotomies; approximately 17 per cent of which were so-called "double cases," in which abdominal and vaginal plastic work were combined. A total of 524, or 13 per cent, were vaginal cases only. There were 2,352 hysterectomies done, including the three types, subtotal, total, and vaginal, which means that the uterus was removed in 58.4 per cent of all operations performed on the service. The vast majority of these were the subtotal type. There were 83 patients who died following hysterectomy, an incidence of 3.5 per cent.

Anesthesia records were not analyzed for the first three years of the period. During these years ether was used in the majority of cases, but the use of spinal anesthesia was steadily increasing. The last three years, spinal anesthesia was used in almost twice as many cases as was ether.

ARRANGEMENT OF THE SIX COUNTY HOSPITAL SERVICES IN GYNECOLOGY

There are six separate services in the gynecologic department, each with its senior and junior attending staff members. During the six-year period, fifteen attending staff members performed

Totals	7,812	183	4,029	121	2,352	83	3,505	524
Per cent	100	2.3	51.6	3.0	58.4	3.5	87.0	13.0

2,954 operations, and ten resident staff members operated a total of 1,075 cases, so that twenty-five operators are represented here.

All patients at this hospital are supposed to be charity patients. The vast majority of them are in poor physical condition on admission. More often than not the gynecological condition bringing them to the hospital is in an advanced stage. Anemias and low general resistance are the rule. All these factors combine to make the patient a below par operative risk.

MORTALITY CLASSIFICATION

For the purpose of analysis, we have divided the mortalities for the period into:

1. *Malignancies*: Twenty-one cases, including four carcinoma of the cervix; five carcinoma of the fundus; one sarcoma of fundus; and eleven carcinoma of ovaries, many with metastases. All except one had laparotomies.

2. *Emergencies*: Seven cases, including four pelvic abscesses; two acute intestinal obstructions; and one ruptured gall-bladder cyst.

3. *Electives*: Ninety-three cases, including sixty-three subtotal, six total, and three vaginal hystertomies; seventeen laparotomies other than hysterectomy; four vaginal plastic cases.

STUDY OF PREOPERATIVE STATUS CONFINED TO ELECTIVE GROUP

For obvious reasons, in our study of the preoperative status of the fatal cases we concerned ourselves only with the latter group, the so-called elective cases. In the malignancies and emergencies, we cannot always control the time or the type of operation, but in the elective group we are dealing with women who are having an operation on advice and not as an immediate necessity. The woman about to undergo an elective gynecologic operation has the right to be safeguarded in every way. As Norris[1] rightly points out, "no operation is so trivial that every step to safeguard the patient should not be employed, nor is any operation entirely free from the danger of a fatal termination. Major risks have to be taken, but every effort should be made to minimize them by preoperative study and care."

PREOPERATIVE DATA—ELECTIVE GROUP

Age.—Age did not appear to be much of a factor. The youngest was eighteen and the oldest seventy years. Sixty-two, or two-thirds of the cases, were between thirty and fifty years of age.

Weight.—There were eighty-one patients of average weight—100 to 150 pounds; five were under 100 pounds and seven over 175 pounds, five of these being over 200 pounds.

Preoperative Period in Hospital.—The average stay of patients in the hospital before operation was over a week. Only two were in the hospital under forty-eight hours prior to surgery. So I think we can say, with regard to preoperative stay in the hospital, that there was a very little so-called "railroading" of patients to surgery.

Blood Studies.— Five patients in the elective group had no blood count at all. An additional six had no hemoglobin nor red blood count determination, making a total of eleven cases operated without a hemoglobin or red blood count being made. Twenty-four patients were admitted with hemoglobin below 70 per cent; five below 30 per cent. In the series, twelve patients were given twenty blood transfusions before operation. Twelve patients went to surgery with hemoglobin below 70 per cent and eleven below 60 per cent, two of these below 40 per cent; and eleven additional cases underwent major elective surgery without any red blood count or hemoglobin studies. Obviously twenty-three patients, or 25 per cent, should not have been operated without further study. Ward[2] stresses the importance of the preoperative prophylactic transfusion, and emphasizes its value, not only in those patients with marked secondary anemia, but also in those borderline cases which show only a moderate loss—65 to 70 per cent hemoglobin and 3,000,000 to 3,500,000 red blood cells. He argues for the adoption of routine preoperative transfusions in patients with

TABLE 2.—*White Blood Count and Differential Before Operation*

7,000– 9,000	40	Polynuclears per cent:	
10,000–12,000	11	65 – 80 per cent......	51
12,000–15,000	7	Below 65 per cent......	14
15,000–19,000	6	Above 80 per cent ...	10
Above 20,000	2	Without Differential..	18
Below 7,000	22

57 per cent had abnormal W. B. C., or was not done.
45 per cent had abnormal Differential, or was not done.

hemoglobin under 70 per cent. An elective blood transfusion is a simple procedure and can be done at the operator's own time; and its advantages to the patient about to undergo surgery are too well known to need further elaboration.

These were the final counts before operation. In fairness it must be stated that some of these high counts were on admission, the patient being in the hospital from several days to a week, oftentimes with an improvement in symptoms and temperature; but the patient was operated without recheck of the white cells. There were twenty-two patients in the elective series with a white cell count below 7,000, a leukopenia suggestive of low resistance reserve. This latter point is borne out by the fact that of the six deaths occurring on the operating table, three had leukopenias. Five patients did not have a white blood count or a differential. Twenty-four, or 32 per cent, of the seventy-five differential counts made were abnormal and there were eighteen not determined, making 45 per cent on this basis and 57 per cent as judged by the white blood count, in which further study should have been done before proceeding with the operation.

Blood Wassermanns. — Sixteen of the elective cases had positive blood Wassermanns. Eight were not recorded. Thus 18.8 per cent of those recorded had positive Wassermann reactions. The general hospital incidence was checked for two years of the period studied, and found to be 4.53 per cent and 4.6 per cent. An incidence of positive blood Wassermanns in the fatal cases of four and one-half times that of the general hospital admission would seem to indicate that this may have been a factor, at least, in some of the cases.

Preoperative Temperature. — Low grade, preoperative temperature has more significance than we like to attribute to it. In our desire to get a patient's operation over with, often reinforced by the patient herself and the relatives, we are prone to disregard low temperature rises. We get away with it many times, but pay the penalty often enough to cause serious retrospection. Polak and Tollefson,[3] in their excellent paper on mortalities, state that a low-grade temperature of 99.2 plus means infection, and that operation in such cases should be postponed until the temperature is normal and has remained so for several days.

Sedimentation Test. — There were only seventeen blood sedimentation tests done on the entire series of 121 cases. Nine tests were under sixty minutes, the time commonly accepted as the lowest rate for safe surgery, and eight of these nine were under forty minutes. The sedimentation test was used in only twelve of fifty proved inflammatory cases in our series. In nine of the twelve in which it was used, its dictum was disregarded. It would seem that we are not taking advantage of this valuable aid to help us solve the perplexing problem of pelvic inflammatory disease.

TABLE 3.—*Temperature Twenty-four Hours Before Operation*

Normal temperature—99 or below	47
99.2–100	29
100 –101	10
101 –102	3
102 –103	3
104.8–	1

61 per cent had temperature 99 or above.
50 per cent had temperature 99.2 or above.

To operate and when, or not to operate at all in a pelvic inflammatory case, is the question daily before the gynecologist. It is now generally conceded that palliative and conservative methods give the best results. According to Aldridge,[4] approximately one-half (48 per cent) of hospital cases either heal completely or become symptom free, making operation unnecessary. Operation is recommended in the chronic stage only if conscientious palliative treatment over long periods has failed, and for disability of attacks which tend to recur in spite of treatment. Then surgery should not be resorted to until the leukocyte count, temperature, and sedimentation time are normal. Polak,[5] Aldridge,[6] Greenhill,[7] and Baer [8] are only a few who concur in this opinion. The Shilling differential blood cell count is often very helpful in doubtful cases.

It is the policy on the gynecologic service to follow the conservative method in the treatment of these inflammatory cases. Many patients are discharged without surgery. In the vast majority of cases surgery was only used after palliative methods failed or after disabling recurrent exacerbations. Practically all were given the benefit of varying periods of preoperative rest in bed. Despite this policy and surveillance, too many were operated before the process was sufficiently quiescent. Pathologic examination showed eight in the series in which the condition was either acute or subacute. A closer check on preoperative status and laboratory requisites would undoubtedly have been of benefit to many of these cases.

Blood Pressure.—Accepting 110 to 150 as the normal limits of systolic blood pressure, we found sixty-three patients in this range. Thirteen were below 110, and seventeen were found above 150. There were seven real hypertensions in the group, the systolic reading ranging from 175 to 220. A survey of the charts of these thirty patients, or 32 per cent, who were either above or below the standard range, shows that many would have been benefited by additional rest before surgery or that further laboratory tests or consultations would have been of benefit.

Urinalysis. — Four patients were adjudged to have more than one plus albumin. Both albumin and pus were found in seven patients; two had positive sugar; two acetone; and in one case casts were found. Two patients had P. S. P. readings below 50 per cent the first hour, one 25 per cent, and another 30 per cent. Eighteen patients, or 20 per cent, had chemical or microscopical pathology in the urine, which increased the operative risk and probably contributed some part in the fatal outcome. Review of one case tells the story. A hysterectomy and bilateral salpingo-oöphorectomy was performed for chronic inflammatory disease, despite two urine examinations showing four plus pus and a preoperative temperature of 101

degrees. She died the seventh postoperative day of general sepsis, immediately after a profuse secondary hemorrhage from the wound. Autopsy showed a large dissecting wound abscess leading from the abdominal wall through the groin into the left psoas muscle, general streptococcic peritonitis, and severe bilateral streptococcic pyelitis. The urine, laden with pus, was significant and undoubtedly played the important rôle in the tragic end.

Table 4 lists the final diagnosis of the fatal cases. Only the major diagnosis is given. Note the high incidence of pelvic inflammatory disease: twenty-nine straight inflammatories, seventeen fibroids with inflammation, and four acute pelvic abscesses, making a total of fifty cases—an incidence of 41 per cent. Pelvic inflammation materially complicates surgical procedures and increases operative risk.

OPERATIVE PROCEDURES IN FATAL CASES

There were 114 laparotomies in the fatal group, among which are included three patients who had vaginal hysterectomies and in whom the peritoneal cavity was entered from below. Eighteen, or 16 per cent, of these were "double cases." Six cases had vaginal operations alone. The final case completing the group of 121 was not operated—death coming after spinal injection and before a proposed posterior colpotomy was started.

There were eighty-three hysterectomies done in the series, and of these seventy-one were the subtotal, nine the total, and three the vaginal type. A total of thirty-one laparotomies, other than hysterectomies were done, including nine for malignant conditions and five in emergency cases.

OPERATING TIME

In most series of fatal cases the operating times are prolonged, and this fact is usually stressed as an important factor in the unhappy outcome. An analysis of the operating times in this series seems to show them to be an exception to this rule.

Table 5 shows the time required for the various operations.

We think these figures bear out the fact that the time consumed at operation in this series was not prolonged. In fact, since many were in technically difficult and complicated cases, the operating times here indicate rapid surgery, and will compare favorably with any nonfatal group for similar operative procedures. Apparently, then, the operating time was not an important factor in most of these fatal issues. In some that were prolonged it was.

ANESTHESIA IN FATAL CASES

In the fatal cases the anesthetic used was about evenly divided between ether and spinal. A total of sixty cases, or approximately 50 per cent, were given ether alone, fifty-three cases, or 44 per cent, were given spinal—ten in the spinal group had to be supplemented, six with ether and four with nitrous oxid; five cases (4 per cent) had nitrous oxid only, and in the remaining three local novocain was used.

TABLE 5.—*Operating Times*

OPERATIVE COMPLICATIONS

The serious complications which occurred during operation are listed in Table 6, and the serious postoperative complications in Table 7.

Seven of the complications listed occurred in the malignancy, and four in the emergency group where there is often ample reason for such catastrophies. It was surprising to see how often the bowel or the bladder was injured and went unrecognized at the time of surgery—the complication becoming apparent only with the development of fistulae or discovered at autopsy, most of them occurring in complicated cases made difficult by inflammatory or postoperative adhesions. In forty-six, or 50 per cent, of the elective group, adhesions were listed as a factor.

Table 8 shows the interval between operation and death. Six patients died on the operating table. An additional nine lived less than twenty-four hours. The largest number of deaths occurred on the fourth and fifth days, when peritonitis takes its greatest toll. A total of eighty-five, or 70 per cent, died within the first ten days after surgery. The remaining thirty-six died at varying intervals, the longest 105 days after operation.

PRIMARY CAUSES OF DEATH

In determining the primary cause of death, the autopsy report, attending surgeon's note when present, resident's, internes' and nurses' notes, were all considered, and usually made the cause clear. Fortunately, 55 of the 121 fatal cases came to autopsy, with an additional case of postoperative intestinal obstruction reoperated, and diagnosis confirmed seven hours before death—really an antemortem autopsy. Thus, in 46.3 per cent of all operative deaths, and in forty-six, or approximately 50 per cent, of the ninety-three elective cases, postmortem examination gave the actual cause of death. We feel this is an excellent autopsy record and worthy of commendation. It is a much higher autopsy percentage than usually reported in similar mortality series. We think this greatly increases the value of any study of mortalities. It was interesting to note how frequently a clinical diagnosis of shock, cerebral accident or cardiac failure was replaced by peritonitis or hemorrhage when the case was subjected to autopsy examination.

Peritonitis was responsible for the death of forty-eight, or 40 per cent, of all cases in the series. Add to these the three cases listed as general sepsis and we have a total of fifty-one, or 42.5 per cent, dying of peritonitis and infection. Several of the deaths from peritonitis were directly attributable to injuries to the bowel, bladder or ureters during operation. The greatest incidence was in patients with inflammatory disease. A total of nineteen patients (20 per cent) in the elective group were presumably infected and were drained, three through the vagina. There were thirty-two (34.5 per cent) associated appendectomies in the elective group. We were unable to draw any definite conclusions regarding the effect of this additional procedure in the fatal outcome.

In no less than four cases the appendix was described by the operator as being "bound down by dense adhesions," and technical difficulty was experienced in removal. In only one case was the appendix directly blamed for a fatal peritonitis. This case at autopsy exhibited an abscess around the appendix stump.

Next to peritonitis is hemorrhage; primary hemorrhage accounting for twelve, and secondary hemorrhage for three, for a total of fifteen deaths, or 12.4 per cent. A total of ten of the fifteen, or two-thirds, of the cases were verified by autopsy. Shock was next, with eleven fatalities (seven clinical and four autopsy diagnoses). It is probable that some of those clinically diagnosed as shock were hemorrhage. Shock and hemorrhage are usually considered together in such a study because, without autopsy, it is difficult to differentiate. Our high postmortem record in the bleeding cases made such a division possible. If we list these two together, we have hemorrhage and shock accounting for twenty-six, or 21.4 per cent, of the total deaths. Add to these twenty-six, another four cases in which hemorrhage was listed as an important contributing cause of death, and we are surprised by the size of the figures. Eight of the fifteen hemorrhage cases (53 per cent) occurred in the inflammatory group where raw surfaces and oozing areas made hemostasis

Autopsies—Elective cases 49.5%

difficult. There were four fatal hemorrhages, however, which occurred in relatively easy cases. All four were subtotal hysterectomies in which the operator, in describing the operation, used terms such as "simple procedure," "minimal shock," "without difficulty." These hysterectomies were completed in an average time of twenty-nine minutes. A few additional minutes for checking or re-ligating vital areas might have changed the outcome.

Embolism shared honors with shock with eleven, or 9 per cent. The following facts stand out in this group: six of the eleven (54 per cent) were afebrile before surgery, which is about the same ratio as all cases. In this group, seven of the eleven (64 per cent) had vaginal plastic work done, either alone or associated with laparotomy; while only twenty-five of the 120 operated cases (20 per cent) had vaginal plastic work. Thus, seven of the embolic deaths occurred in the twenty-five vaginal cases, an incidence of 28 per cent, while the remaining ninety-five cases, in which no vaginal plastic work was done, accounted for only four embolic deaths, an incidence of 4.2 per cent. Of the eleven, four, or 36 per cent, had uterine fibroids, whereas fibroids made up 30 per cent of the entire group. In only two of the seven autopsied were thrombi or pathology demonstrated in the pelvic veins.

Myocardial insufficiency followed with eight, and cardiorenal disease with one, making a total of nine, or 7.4 per cent, in which cardiac failure was the primary factor. Four of the eight were obese; only three gave any indication in their histories of possible cardiac pathology. There was no record of previous decompensation in the entire group. In the preoperative examination definite cardiac pathology was found in three, and in two others it was questionable. In this group, six of the eight had fibroids of the uterus and one of the two remaining had a fibroid polyp. The association of myocardial disease and fibroids has before been noted repeatedly. Excessive surgery for a minor complaint was the outstanding factor in the cardiorenal death.

Pneumonia and malignancy and cachexia have six each, or 5 per cent. Of the six patients who died of pneumonia, four were aged—over sixty years. Only one showed pulmonary pathology at preoperative examination. Respiratory anesthesia did not prove to be the chief offender. On the contrary, three of the six cases had only spinal; one had spinal, supplemented with nitrous oxid and ether; one had only ether and one had local novocain.

The six deaths that occurred on the operating table are of sufficient interest to analyze briefly. Pelvic inflammation was present in five of the six; two were obese, 220 and 250 pounds; two had cardiac disease; three had leukopenias, and one no blood count at all. Ether was the anesthetic in four, nitrous oxid and ether in one, and spinal in one. All cases were autopsied and causes of death were as follows: Operative shock, two; cardiac failure, two; anesthesia, two. One of the two anesthetic deaths had ether for eighty-five minutes, the operation requiring seventy minutes. Autopsy report was "etherization with somewhat persistent thymus weighing 33 grams." The spinal death was the only case in the entire series not operated. A posterior colpotomy was proposed, but the patient died five minutes after 100 milligrams of novocain had been injected. The obesity

75% died of peritonitis.

(220 pounds), low blood pressure (80/60), the Trendelenburg position, and the general toxemia from peritonitis secondary to a pelvic abscess, were the factors which made the patient a poor spinal risk.

COMMENT

An analytical review such as this must necessarily be incomplete. It is always of more interest and benefit to the reviewer than to the reader. A survey of the entire study brings up many interesting sidelights and points for discussion. The following seem timely and to be of some value:

Total Versus Subtotal Hysterectomy.— In recent years there has been considerable interest in the advantages of total versus subtotal hysterectomy. In our series of fatal cases there were too few total hysterectomies to justify definite conclusions. However, certain facts are interesting and somewhat indicative. Six were done for benign conditions, and three for malignancies. The operating time averaged 102 minutes, 41 minutes longer than the average for the subtotal operation. In only two cases out of nine were no special complications mentioned in the dictated operative record.

In our series the total hysterectomy operation required 67 per cent longer time to perform; was replete with serious operative and postoperative complications, and 75 per cent of the cases died of peritonitis.

Diagnostic Dilatation and Curettage.—The diagnostic dilatation and curettage seems to have lost its popularity. This valuable diagnostic procedure was not employed once in the entire series of 121 fatal cases. One dilatation of the cervix was done and a pyometria discovered which prevented a contemplated Watkins interposition operation. A diagnostic dilatation and curettage, and pelvic examination under anesthesia, often help materially to clear up a diagnosis, and shorter and simpler operative procedures can be done, amply caring for the pathology. A review of the cases shows it would have been of decided value in at least eleven cases, and undoubtedly would have changed the operative procedure in an additional five cases of malignancy. The question is raised, should not all puzzling menorrhagias and metrorrhagias have a diagnostic curettement?

Radiotherapy.—While on the subject of more conservative procedures being curative, the question of radiotherapy comes up. In some of the patients in this series its use might have been seriously considered. A careful study of the cases, constantly keeping in mind the conditions, indications, and especially the contraindications for its use, shows that radium might have been used to advantage in some twenty patients in the group. It would have been satisfactory in three of the eight fatal myocardial cases.

Radiotherapy has a definite place in gynecology. It must be used with judgment and with proper regard for its indications and contraindications. It is not a "cure-all," and has definite, sharply defined limitations. Keeping this in mind, it is often the most conservative curative measure—many times life-saving—where other operative procedures would and do prove fatal.

SUMMARY OF STATISTICS

In a series of 4,029 gynecologic operations at the Los Angeles County Hospital there were 121 deaths—a gross operative mortality of 3 per cent. Two thousand three hundred and fifty-two were hysterectomies, with a mortality of 3.5 per cent. Eighty-seven per cent of the entire group were laparotomies and 13 per cent vaginal cases only.

In the 121 cases, twenty-one were malignancies, seven were emergencies, and ninety-three were so-called elective cases. In the elective group the more frequent diagnoses encountered were: pelvic inflammatory, twenty-nine; fibroids and inflammatory, seventeen; and fibroids, nineteen.

The most frequent causes of death were as follows: peritonitis and sepsis, 42.5 per cent; hemorrhage and shock, 21.4 per cent; embolism, 9 per cent; cardiac failure, 7.4 per cent; pneumonia, 5 per cent; and malignancy and cachexia, 5 per cent. Autopsies were performed in 46.3 per cent of all cases in the series, and in approximately one-half of the elective group.

There were twenty serious complications during operation, and thirty-eight serious postoperative complications.

CONCLUSIONS

Preoperative study and care are of the greatest importance. Despite the average stay of one week in the hospital prior to operation, inadequate studies were made in too many of the cases. Additional laboratory work and more consultations would have benefited many patients.

Too often, the physical and laboratory findings and important preoperative requisites that make for good operative risks were disregarded.

More preoperative blood transfusions in the anemic and border-line cases are indicated.

Despite knowledge and efforts to the contrary, patients with pelvic inflammatory disease are being operated too early and too often. The sedimentation test is not being used sufficiently in these cases.

A closer check of the patient's complaints with the operative procedure would prove of value. The diagnostic dilatation and curettage should be used more frequently.

In certain poor-risk cases where indications are met, radiotherapy should be considered.

Considering the type of patients and the operative risks, the operative mortality here reported compares favorably with that reported by similar clinics.

DISCUSSION

L. M. Emge, M. D. (2000 Van Ness Avenue, San Francisco). — The excellent analysis presented by Doctors Marshall and Thompson constitutes a very courageous document. I have a great deal of respect for the chief of a large service who has the courage to permit the publication and discussion of such a document. At best, any analysis of this sort will invite some just, and some unjust, criticism. For instance, why should patients be operated on during the acute stage of pelvic inflammatory disease, unless it be for the simple drainage of a pelvic abscess? The essayists point out that all surgical patients are housed for at least one week prior to operation. This certainly is enough time to segregate the poor from the good surgical risks, so that there remains no excuse for undertaking major surgery on patients who are still in the stage of acute infection, or who otherwise constitute a questionable surgical risk. There certainly exists no emergency in most of these patients; therefore, why not reduce the surgical risk by conservative medical measures? Most operations can wait. I appreciate that in a large service the head of the department cannot be in such intimate contact with details that he can pass on every case. This is a matter for the division chiefs to decide. In an analysis such as presented here, the work of the individual division should be compared, so that one might learn what operators have the lowest mortality. I am sure this would be very salutary and invite competition for lower mortality records.

I do not like to appear to be critical, and I do hope that my remarks will be considered in the spirit of friendly analysis. May I, therefore, be pardoned for saying that the high mortality in cases of malignancy indicates a rather reactionary method of surgical therapeusis; for, certainly, surgery of the malignant cervix must be seriously questioned except in the very early localized tumors, and even these are perhaps more successfully treated by irradiation, as far as mortality is concerned.

Table 1.—*On Operations at Lane and San Francisco Hospitals*

OPERATIONS—1924-1934		Deaths	Per Cent
Lane Gynecological Service:			
Major	995	22	2.2
Minor	703	2	0.28
Total	1,698	24	1.4
San Francisco Hospital and Stanford Gynecological Service:			
Major	1,379	46	3.3
Minor	1,844	3	0.1
Total	3,223	49	1.5

Table 2.—*On Hysterectomies at Lane and San Francisco Hospitals*

HYSTERECTOMIES—1924-1934		Deaths	Per Cent
Lane Hospital:			
Abdominal, Complete	307	10	3.2
Abdominal, supravaginal	265	8	3.0
Vaginal	73	0	
Total	645	18	2.8
San Francisco Hospital:			
Abdominal, complete	196	8	4.0
Abdominal, supravaginal	408	12	2.9
Vaginal	28	4	14.3
Total	632	24	3.9

May I also say that the time element in operations is not anywhere nearly as important as we are made to believe; for good anesthesia, gentle handling of tissues, the selection of patients, the preoperative care, and transfusions permit a more deliberate surgical approach, with a resultant reduction in postoperative complications. Fifteen per cent of all deaths because of secondary hemorrhage after hysterectomy is a rather serious indictment against spectacular speed in surgery, unless it can be blamed upon lack of skill.

The surgical service of the department of obstetrics and gynecology at Stanford is not as large as the one represented here by Doctors Marshall and Thompson. In our combined clinic services at Lane and San Francisco hospitals, over a period of ten years, there were 4,921 operations, with slightly less than 1.5 per cent mortality. If you will compare the figures between the two services, you will also see that there is also a slight difference in mortality rates, in which that of the service at San Francisco Hospital corresponds closely to the figures shown here.

Nevertheless, the total figure for all operations is considerably lower because of the dilution by minor operations. If you take the hysterectomies, on the other hand, and compare the end-results of our services with that of the Los Angeles General Hospital, you will find that the total figure is approximately the same, although there is again a marked difference between the figures of the Lane Hospital Service, as compared with the San Francisco Hospital service. I particularly point to the difference in vaginal hysterectomies, in which there were no deaths on the Lane service. Our figures bring out one factor: that the mortality rate for complete and supravaginal hysterectomies may be kept at an equal level, as shown in the figures of the Lane service. It is also interesting to note that hysterectomies made up about 46 per cent of the major operations at our San Francisco Hospital service, and 65 per cent at the Lane service.

Peritonitis was the commonest cause of death on both services, constituting about one-fourth of our mortality. We had no deaths from secondary hemorrhage. Cardiac failure and intestinal complications made up the bulk of the remainder of the causes. Embolus and shock were rare. Carcinomatosis, discovered at exploratory laparotomies, is included in this group as a cause of death.

The number of operators for the two services varies between nine and ten. . . .

May I say, in conclusion, that the figures I have shown here are not presented in a spirit of righteousness, but only as a matter of comparison. I consider it a great privilege to have been asked to discuss this paper, and I wish to extend congratulations and thanks of this section to the essayists for having undertaken this extensive piece of work.

CARDIOSPASM

SUCCESSFULLY TREATED BY HYDROSTATIC DILATATION

By Gunther W. Nagel, M.D.
San Francisco

Discussion *by William J. Kerr, M.D., San Francisco, and William Dock, M.D., San Francisco.*

CARDIOSPASM, or spasm of the lower end of the esophagus, is a well-recognized clinical pathologic entity. The obstruction is intermittent at first and results in gradual distention of the esophagus. In advanced cases obstruction may be continuous and almost complete. Dysphagia and substernal pain are prominent symptoms.

Treatment consists of forceful dilatation of the spastic area. Different means have been employed to accomplish this. A satisfactory method is hydrostatic dilatation with the Plummer dilator.

In reviewing the histories of patients with cardiospasm seen at Stanford Clinic and in private practice, it is apparent that previous treatments, such as the administration of antispasmodic drugs and the passing of bougies, have given unsatisfactory results. The following cases are presented to illustrate the good results obtained by forceful dilatation of the spastic area.

REPORT OF CASES

Case 1.—No. 104849. Female. Age, 57. Six years ago the patient was suddenly seized with a gagging and choking sensation after eating. Following this she had periodic attacks of difficulty in swallowing both liquids and solids. She did not vomit food, but regurgitated considerable saliva and mucus. The food seemed to stick under the lower end of the sternum. X-ray showed tremendous dilation of the esophagus due to cardiospasm. She had lost forty pounds within the six months previous to examination. The Wassermann reaction was negative. Other laboratory examinations were of no significance.

Following hydrostatic dilatation she was completely relieved of her symptoms, and x-ray showed the esophagus to empty rapidly.

Two months after dilatation the patient remained relieved of her symptoms. She has not been heard from since.

* * *

Case 2.—No. A9613. Female. Age, 27. A year ago the patient began to have attacks of pain in the epigastrium, coming on usually at night. For two months previous to examination she had difficulty in retaining food, even when taken in small amounts, regurgitating both liquids and solids. Occasionally after eating she had a sensation of the stricture opening up and allowing food to pass through. She lost twenty-seven pounds during this period. X-ray showed a spasm of the cardia with a small amount of barium retained in the esophagus after six hours (Fig. 1). Other laboratory examinations, including the Wassermann test, were negative.

Following hydrostatic dilatation she reported that she had occasional slight substernal pain early in the morning, but she had no difficulty in swallowing and did not regurgitate.

Two and one-half years later the patient reports that while she has been very much improved, occasionally she still has a little difficulty in swallowing. She has gained eleven pounds since dilatation.

* * *

Case 3.—No. A11660. Female. Age, 39. For a period of four months the patient had increasing difficulty in retaining food. At the time of examination apparently nothing she ate was retained, and she lost fifty pounds in weight. The x-ray diagnosis was cardiospasm. The hemoglobin test showed 66 per cent; otherwise the laboratory findings were negative.

The passage of a No. 60 French olive failed to give relief, so hydrostatic dilatation was done. She complained of considerable soreness over the lower part of her chest following this procedure, and developed a patch of pneumonia in the lower left lobe with possible mediastinal effusion. This complication may have been due to a slight splitting of the esophagus as a result of the dilatation. She made a quick recovery, has regained her normal weight and has been entirely cured of her dysphagia. When last heard from, two and one-half years after the treatment, she had no recurrence of her former symptoms.

* * *

Case 4.—No. A19329. Male. Age, 48. A year previous to our examination this patient's trouble began with a feeling of fullness in the epigastrium. For a period of five or six months he had been vomiting at night shortly after going to bed. These symptoms gradually grew worse. The x-ray showed spasm of the lower end of the esophagus (Fig. 2). Laboratory findings, including a Wassermann test, were negative.

Following hydrostatic dilatation, the patient was completely relieved of his symptoms and has remained so for a period of a year and a half. He has no difficulty whatever in swallowing, and feels very well.

* * *

Case 5.—No. 177949. Female. Age, 60. The patient's complaint was difficulty, for a period of six years, in swallowing. She had lost 100 pounds in weight. Two and a half years previous to examination, a diagnosis of inoperable cancer of the esophagus was made elsewhere.

She had a marked secondary anemia—hemoglobin, 68 per cent, red blood cells, 3,600,000. The x-ray's diagnosis was cardiospasm (Fig. 3).

An abdominal exploration was done, and the cardiac end of the stomach and lower end of the esophagus were found to be surrounded by adhesions, which were freed. Following this operation the patient continued to regurgitate practically everything she ate. Two weeks later hydrostatic dilatation was done, and she was entirely relieved of her dysphagia. She gained eleven and a half pounds during the following six months.

She writes, two and a half years following dilatation, that she does not feel well and that she regurgitates her food occasionally. She has numerous complaints not related to the gastro-intestinal tract.

* * *

Case 6.—No. A5594. Female. Age, 26. About a year ago the patient began to experience a feeling of weight in the epigastrium, which appeared about twenty minutes after eating and was frequently followed by regurgitation of ingested food. She had no pain.

A diagnosis of cardiospasm was made and the spastic area was dilated elsewhere by means of an air-filled balloon. She did not obtain relief from this procedure. Following hydrostatic dilatation, she was completely relieved of all her symptoms.

* * *

Case 7.—No. 197595. Female. Age, 33. The patient entered the clinic complaining of cough, fever, and loss of weight. A diagnosis of active pulmonary tuberculosis was made. In addition, she complained of difficulty in swallowing and, for a period of six years, frequent regurgitation of undigested food. The x-ray revealed a spasm of the cardiac end of the esophagus (Fig. 4). Sputum showed tuberculosis bacilli. Other laboratory examinations, including Wassermann test, were negative.

Hydrostatic dilatation was followed by complete relief of the dysphagia. Marked improvement in the pulmonary condition also followed after treatment in a sanitarium. At the present time, three and a half years later, the patient reports that she is in good health, has gained twenty-two pounds, but still has some slight difficulty in swallowing if she takes solid food in large amounts.

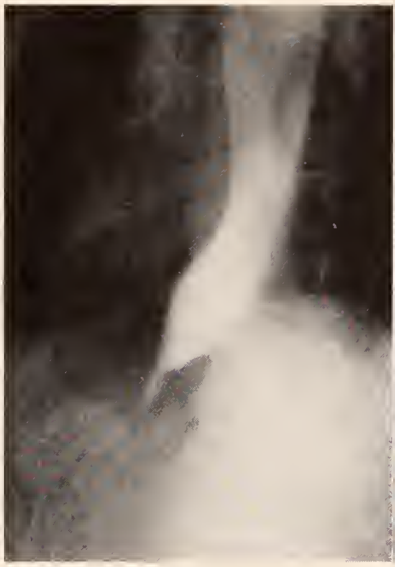

Fig. 1

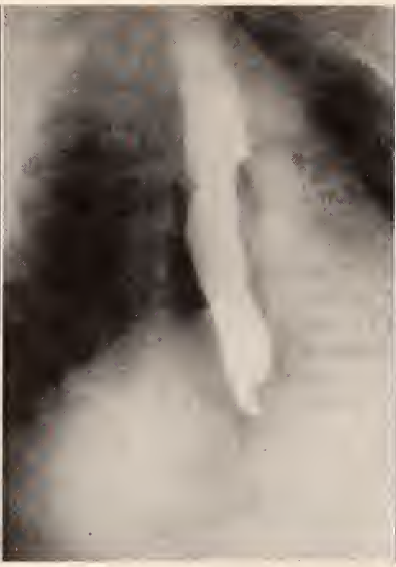

Fig. 2

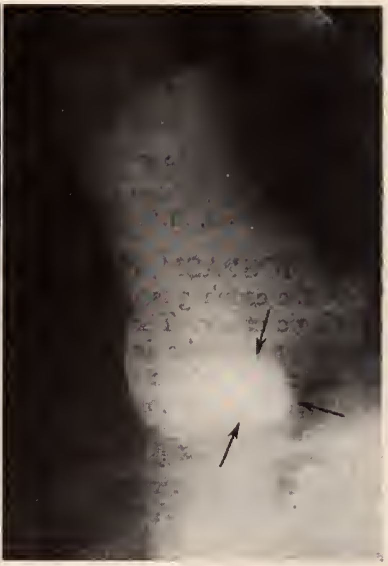

Fig. 3

Fig. 1.—Cardiospasm showing typical cone-shaped dilatation of the esophagus above the spastic area.
Fig. 2.—Cardiospasm. Atypical x-ray picture difficult to differentiate from cancer of the cardia.
Fig. 3.—Cardiospasm with markedly dilated and tortuous esophagus.

Case 8.—E. O. M. Male. Age, 48. Intermittent dysphagia over a period of four years was the patient's complaint. Liquids and solids appeared to stick under the lower end of the sternum; and in order to aid their passage he had formed a habit of standing while eating and forcing the food down with vigorous swallowing movements. An attempt had been made elsewhere to dilate the spastic area with the Plummer dilator, but he obtained no relief. Apparently the dilator had not been properly placed, as the patient suffered no pain while the bag was being distended up to 26 feet of water pressure. This patient also had a complicating pulmonary tuberculosis.

Following hydrostatic dilatation, he was completely relieved of his dysphagia. After a period of five months he still has no difficulty in swallowing.

* * *

Case 9.—No. A36257. Male. Age, 40. This patient's complaint was intermittent dysphagia of five years' duration. Solids and cold liquids caused the most trouble, and appeared to stick in the epigastrium. While his food was thus lodged he had severe cramps under the sternum. He obtained relief by vomiting or taking warm liquids. The x-ray showed a cardiospasm with 25 per cent residue in the esophagus after six hours. He was dilated with a 45 French olive followed by a 60 French olive, and entirely relieved of his dysphagia. Four months have elapsed since this was done, and should his symptoms return, hydrostatic dilatation will be done.

* * *

Case 10.—E. T. Female. Age, 21. For the past two years ingested food, both liquid and solid, appeared to lodge for a time in the lower end of the esophagus. This patient had considerable epigastric pain. The x-ray showed cardiospasm.

Following hydrostatic dilatation the food passed freely into the stomach, pain ceased, and she gained ten pounds in weight. She had no return of symptoms a year after dilatation.

* * *

Case 11.—S. C. Male. Age, 23. Beginning seven years ago this patient commenced to have intermittent attacks of difficulty in eating. Liquids and solids lodged in the lower end of the esophagus, and caused considerable pain. Later his symptoms were more constant and gradually increased in severity. Small amounts of food eventually passed through, but large quantities were regurgitated.

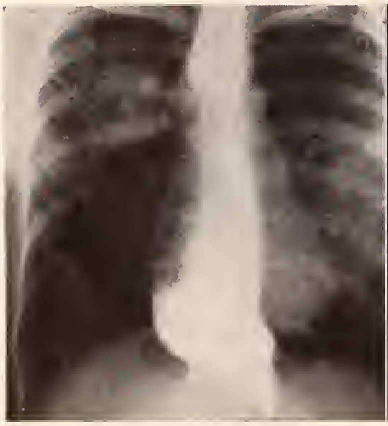

Fig. 4

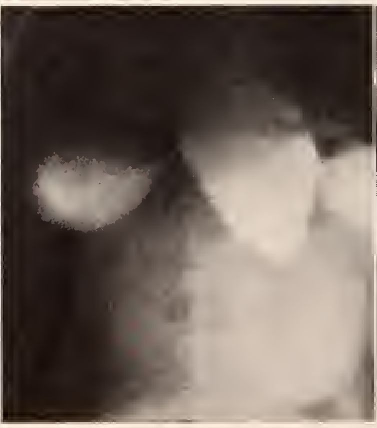

Fig. 5

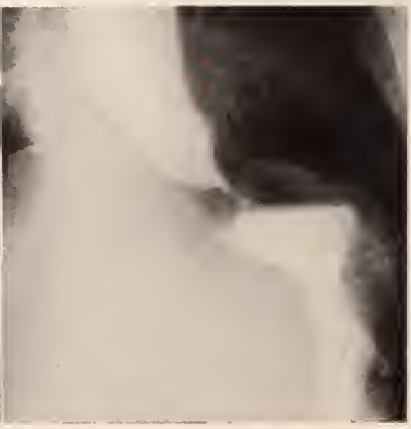

Fig. 6

Fig. 4.—Cardiospasm with tortuous and dilated esophagus and pulmonary tuberculosis.
Fig. 5.—Cardiospasm with marked dilatation of the esophagus.
Fig. 6.—Cardiospasm with some barium passing into the stomach.

Several physicians were consulted at different times, all of whom made the diagnosis of cardiospasm, but none of whom was able to give him any relief.

It is now six years since hydrostatic dilatation was done. He was immediately relieved of his symptoms, and has had no recurrence of his trouble. He has gained fifty pounds in weight.

* * *

Case 12.—H. D. Female. Age, 28. The patient had had intermittent difficulty in swallowing both liquids and solids for a period of eleven years. Her trouble had been gradually growing worse, and six months previous to examination she took chloroform liniment with suicidal intent. Prompt attention saved her. The x-ray showed a spastic cardia and dilated esophagus (Fig. 5). Complete relief from symptoms followed hydrostatic dilatation.

* * *

Case 13.—T. J. D. Female. Age, 25. For three and one-half years the patient had difficulty in swallowing liquid and solid food. At the onset this condition had been intermittent, but for fourteen months previous to examination it had become constant. Pain became an increasingly severe symptom. The x-ray showed a cardiospasm (Fig. 6). An attempt to dilate the spastic area by esophagoscopy was unsuccessful on two occasions.

Dysphagia has been entirely cured following hydrostatic dilatation. She recently complained of some discomfort after meals, but this has been relieved by a little care in the selection of her food, something which had not appealed to her after so long a period of dysphagia.

* * *

Case 14.—M. G. Female. Age, 23. The patient for a year complained of difficulty in swallowing. The onset was quite sudden, with the lodging of food under the lower end of the sternum. Liquids caused as much difficulty as solids. She lost twenty-five pounds in weight during the year. A number of physicians were consulted, but no relief was obtained.

The x-ray showed cardiospasm, with considerable dilatation of the esophagus.

Dilatation was done up to fifteen pounds of water pressure, but this gave only temporary relief. A second dilatation was done a month later and the pressure used increased to twenty-five pounds. This has given complete relief, and she has gained thirty pounds in weight. It is fifteen months since the second dilatation.

* * *

Case 15.—J. M. Female. Age, 30. This patient complained of difficulty in swallowing since childhood. Pain under the sternum was a distressing symptom. She had been dilated with bougies several times, but had been little relieved. The x-ray showed a typical cardiospasm. The spastic area was dilated with a size 60 French olive.

The patient has been relieved of her dysphagia, but will probably require hydrostatic dilatation at a later date.

SUMMARY OF CASES

The histories of fifteen patients with cardiospasm have been reviewed. Eleven patients were women and four were men. The oldest patient was sixty years of age, the youngest twenty-one years of age, the average age being thirty-five years. The average duration of symptoms was five years. Thirteen patients were treated by hydrostatic dilatation; two were dilated with a size 60 French olive. Twelve patients have remained cured over periods ranging from several months to over six years. The other three patients were greatly relieved of their symptoms, but still complained of slight dysphagia at times.

MEDICAL TREATMENT OF CARDIOSPASM

Mild cases of cardiospasm without x-ray evidence of delay in emptying the esophagus may be successfully treated by medical means. An illustrative case follows:

No. A24968. Female. Age, 60. The patient complained of spells of nausea and vomiting for the past seventeen months. During attacks she experienced a sense of constriction under the lower end of the sternum. The x-ray showed a normal esophagus. The diagnosis was mild cardiospasm. The patient was given tincture of belladonna and elixir of sodium bromid, and two months afterward she reported that she was much improved and had very little difficulty in swallowing.

SURGICAL TREATMENT OF CARDIOSPASM

In a very occasional patient simple dilatation cannot be done and surgery is indicated. Doctor Judd and I have reported such a case. In this patient the esophagus was so dilated and tortuous that, while the thread was successfully swallowed, it was, nevertheless, impossible to pass sounds without great danger of injuring the esophagus. A gastrostomy was done, and the cardia dilated manually from below. The patient was much improved following this, but not entirely cured. Some months later hydrostatic dilatation was successfully done.

Plastic operations have been done on the cardia, but they have not been uniformly successful and the mortality is quite high. Hydrostatic dilatation in most cases is simpler, more satisfactory and much less risky than operative procedures.

INCIDENCE OF CARDIOSPASM

Cardiospasm is considered quite rare, but I believe that mild forms of it are more common than is generally thought. Temporary spasm of the cardia has undoubtedly been experienced by large numbers of individuals. Almost everyone has at times had severe substernal pain on gulping some cold liquid when he was hot and tired. This is a temporary cardiospasm and in most individuals the discomfort suffered is sufficient warning to prevent a repetition of its cause.

Cardiospasm occurs most frequently in relatively young women. It may be associated with other lesions, notably cholecystic disease and peptic ulcer, but usually it exists alone. Though a definite etiology has not been established, it is considered to be of nervous origin. The condition, however, is definitely not a neurosis, but a true organic lesion.

DIAGNOSIS

The majority of patients with cardiospasm give a history of periodic spells of difficulty in swallowing lasting over a period of years. In the early stages the spasm is intermittent, and there may be long periods of freedom from trouble. Gradually, however, the spasms occur with more frequency, and finally the patient is unable to take any type of food in comfort. In the beginning liquids, especially cold liquids, often cause more trouble than solid foods. In the later stages solid foods also give trouble. The patients usually describe the ingested food as sticking or lodging under the lower end of the sternum. They adopt various procedures to force the food through.

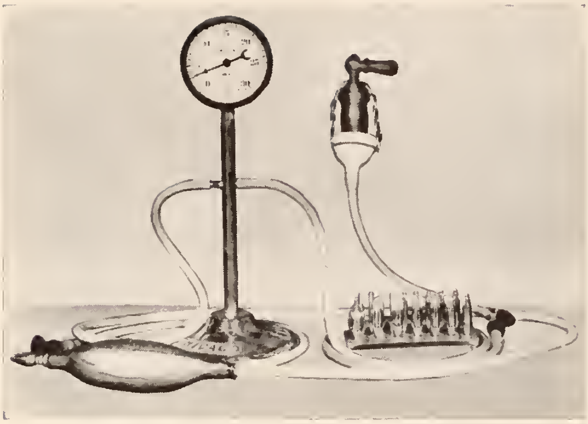

Fig. 7.—Plummer hydrostatic dilator.

Some obtain relief by standing and drinking large quantities of fluids, forcing the spasm by means of pressure from above. Others, by closing the glottis, seem to be able to compress the esophagus by means of increased intrathoracic pressure and thus force the food through the constricted area. Still others find that they can eat only small amounts at a time and, following varying intervals, the spasm temporarily releases itself. To obtain relief, almost all the patients in advanced cases regurgitate a certain amount of the food taken.

In spite of difficulty in swallowing, many of these patients go on for years without any great loss of weight or strength, while some become markedly emaciated and anemic.

The condition has to be differentiated from cancer of the esophagus and benign organic stricture. The long history, its intermittency in the early stages, and the characteristic x-ray appearance differentiate cardiospasm from cancer. However, in two of my patients a previous diagnosis of cancer had been made. Organic stricture can also be differentiated on the basis of the history and x-ray appearance.

PATHOLOGY

The spasm occurs usually in the esophagus above the cardia at the level of the esophageal hiatus of the diaphragm. The esophagus becomes gradually dilated above this point. The dilatation may be two or three times the normal diameter of the esophagus, and in some instances the saculated esophagus appears by x-ray to take up as much as a third of the available space in the thoracic cavity.

Pathologic examination in such cases shows the wall of the esophagus to be greatly thickened, and firm at the point of narrowing, while above, in the dilated area, the musculature is more or less hypertrophied, but shows no other marked changes. Usually in advanced cases there is some evidence of inflammatory reaction. There may be small superficial mucosal ulcers present, but these appear to be secondary to the spasm and not a cause of it. So-called peptic ulcers in the lower end of the esophagus occasionally occur, and may produce a certain amount of spasm; but such cases are not included in this group.

TREATMENT

Cardiospasm is treated by forcefully dilating the constricted area. The method used in this series was that of hydrostatic dilatation by means of the Plummer bag, with a previously swallowed silk thread as a guide (Fig. 7). This is the method described by Plummer and Vinson. The procedure is as follows:

The patient is first instructed to swallow five to eight yards of silk thread. The purpose of the thread is to furnish a guide for the passage of sounds and dilator. It is an absolutely essential part of the procedure, in that it inevitably guides the instrument to the proper opening, and prevents the possibility of forcing the dilator into a false pocket and thus rupturing the esophagus. A glance at some of the x-rays in these cases shows that the esophagus at times turns almost at right angles before entering the stomach, and illustrates how easily an independently passed sound might perforate it (Figs. 3 and 4). A spool of buttonhole silk, size "D," is satisfactory, and is easily obtained. The first few feet are swallowed slowly so that the end of the thread may find its way through the point of spasm. After this it may be swallowed a little more rapidly until it passes through the stomach and into the intestines. When this has occurred, it is drawn down by the peristaltic action of the intestines and soon becomes firmly anchored. It is advisable to tell the patient to fasten or hold the thread while eating so that too much is not taken in at a time, which might result in the thread becoming snarled. From twenty-four to thirty-six hours is the usual time required for the thread to become sufficiently well anchored to serve as a guide for the passage of sounds. Patients frequently protest in the beginning that they will be unable to swallow the thread, but when properly coaxed they never fail to do so, and it always passes through even the smallest stricture.

Before dilating, the esophagus should be empty to prevent regurgitation and possible pulmonary complications, as a result of the passage of regurgitated material into the trachea during instrumentation.

The patient is placed in a low chair with a curved seat, designed to prevent his slipping forward during the passage of the instruments. The dilatation is done without anesthesia, because one of the determining points as to whether the dilator has been properly placed or not is the pain which the patient has at the time of dilatation.

A No. 45 French olive, with a filiform tip, is first fastened to a whalebone staff and guided into the esophagus over the previously swallowed thread which must be held taut during this procedure. At the point of spasm, a resistance to its passage is felt; but with moderate pressure this is overcome and the dilator slips through into the stomach. This procedure confirms the diagnosis of spasm as against an organic stricture, which is unyielding and does not permit the passage of so large a dilator. The distance of the strictures from the patient's incisor teeth is marked off on the whalebone staff. This distance is now measured off on the hydrostatic dilator and it is passed in a similar manner over the thread. When the dilator is in the correct position, the water is turned on and the pressure in the bag is increased up to the desired point by compressing the outlet tube. As soon as the gauge registers the desired pressure, usually from 15 to 20, the water is released and the bag removed. The thread is cut off close to the patient's mouth and the remainder swallowed.

RESULTS OF TREATMENT

In nearly all my cases a single dilatation has been successful. In two patients two dilatations were necessary. In one instance the patient developed a pulmonary lesion, which may have been the result of a slight splitting of the esophagus or an aspiration pneumonia. The patient recovered after a brief illness. In two patients the hydrostatic dilator was not used, but a size 60 French olive was used in its stead. These patients also obtained complete relief.

Patients usually complain of a little soreness under the lower end of the sternum after treatment, but this passes off after a day or two. The spasm is relieved immediately, and the patients are able to eat a large meal without difficulty a few hours after the procedure.

CONCLUSION

The results following hydrostatic dilatation of cardiospasm are so gratifying to both patient and doctor that it seems worth while to again call attention to this fact.

2000 Van Ness Avenue.

DISCUSSION

William J. Kerr, M.D. (University of California Hospital, San Francisco).—It has given me a great deal of pleasure to read Doctor Nagel's instructive paper on "Cardiospasm." There is not much doubt that most of the patients described by Doctor Nagel, in reporting his experience in fifteen cases, have reached the stage where forceful dilatation of the cardiac sphincter is perhaps necessary in their treatment. The condition is somewhat analogous to the pylorospasm occurring in infants, where the tissue becomes extremely rigid and would remain permanently so unless some mechanical measures were employed to relieve it. In my opinion, these two conditions are examples of structural change which results from long-standing functional disturbance.

If one can recognize patients who have a tendency to cardiospasm, and can approach them from the standpoint of functional disturbance, going into their psychological problems and treating them first in an attempt to remove the cause of their trouble or to make the situation in which they find themselves comprehensible to them as a cause for their symptoms, I am sure that a good deal can be done to prevent the later stages which Doctor Nagel rightfully suggests should be treated by forceful dilatation. It may be necessary to make use of sedatives and antispasmodic drugs, and to treat the autonomic nervous system either on the parasympathetic or, perhaps, on the sympathetic side; but this must be handled in an individual manner on the patients as they present themselves. If one follows the directions which have been given by the author, there is very little probability of injury to the tissues around the lower end of the esophagus, and one is not likely to have mediastinitis or other local infections arise following trauma to the tissues and perhaps extension of infection from the lumen of the esophagus or stomach.

William Dock, M.D. (Stanford University Hospital, San Francisco).—The treatment of cardiospasm by forceful dilatation, with a dilator of large caliber, is one of the most satisfactory therapeutic procedures in all medicine, as those of us who have followed Doctor Nagel's cases, or cases similarly treated elsewhere, are well aware. While the treatment must be used with strict care as to its details, and preferably only after much experience in assisting at the operation, the actual discomfort and risk to the patient are not great enough to justify other forms of therapy except under unusual circumstances. Mild cases unable to obtain such therapy may be controlled by allowing them to pass a mercury-weighted Ewald tube before and after meals, as described by Arthur Hurst in 1924, and very long-standing cases with tortuous gullets may require gastrostomy, retrograde dilatation and other procedures; but the majority of instances met with in practice are best managed by the technique described here. It should be noted that the disturbance affects the lower esophagus, and is due to its failure to relax as the peristaltic wave comes down. A tube passes through easily, and is not gripped as the spastic anal sphincter grips the examining finger. But only forceful overdilatation can be relied on to give more than transient relief.

THE LURE OF MEDICAL HISTORY†

MEDICAL CONDITIONS, PRACTICES, AND FOUNDATIONS IN THE CONTINENTAL COLONIES*

By Harold Hanzlik†
San Mateo, Calif.

PART II‡

INDIAN CONTRIBUTIONS

HOWEVER, Governor Winthrop's son, J. Winthrop, Jr., copied some worth while things from his red-skinned friends. A short discussion of these will indicate the contributions of the Indians. Doctor Winthrop praised their use of tobacco, saying, "The juice of the green leaf healeth green wounds, although poysened" (Packard). The juice referred to by Winthrop contains nicotin, which acts as an antiseptic, but, if used too liberally, as a strong poison. Winthrop adopted this remedy for his formulary. The Indians, like the colonists, knew about cauterizing wounds to prevent infection. The Indians used cauterization in a very novel way to keep prisoners from running away. Winthrop states that the Indians cut away half of a prisoner's foot, then took the skin and wrapped it over the wound and cauterized it, thus preventing the prisoner from running because he had only half a foot. The Indians also knew about cascara, a drug official in modern pharmacopeias, and used it both for painting themselves and as an emetic for the sick.

However, the Indians were worse off than the colonists when it came to epidemics. An old English writer states, "They (Indians) were also considerable heretofore, about 3,000 men. . . . But they also were almost totally destroyed by the great sickness (plague) before mentioned, so that at this day they are not above 250 men besides women and children" (Blanton). The reason the Indians suffered was that they lived in much filth. They sometimes housed as many as nineteen persons in one tent. It is no small wonder, therefore, that they had great epidemics and sickness. Malaria was common among them because they drank water from stagnant pools in which the mosquito laid its eggs. On the other hand, the colonists did not suffer as much, because they did not walk among the natives during the epidemics. In all probability the epidemics were not contagious. It is more likely the colonists were cleaner, and kept themselves covered more, thus reducing the chances for mosquito bites and malaria. There is no doubt that the colonists received some valuable remedies, as well as some worthless ones, from the Indians. Sweating in tents was extensively employed by the Indians, and this practice was adopted by the colonists and their doctors; but its proper use was apparently not correctly understood. And disease, of course, also was not understood, and only scattered references to this phase are made by colonial writers.

MEASLES

Governor Winthrop's descriptions of diseases are brief, and therefore little is actually known about the prevailing sickness of the Colonial times in New England. However, a most prevalent disease at that time was measles, which was not limited to the Massachusetts colony, but was found also in the Carolinas, Virginia, and in the middle states. For, in Philadelphia, there was quarantine against measles as early as 1736, and perhaps earlier. New York also passed laws, in or about 1650, prohibiting the docking of ships that carried measles. Once, however, ships got into port without knowledge of the local authorities and as a result there soon appeared an epidemic. The careless attitude of the officials and people often made the work of these early physicians extremely difficult. They were forced to combat not only disease, but also the puritanic and straight-laced virtues of the God-fearing populace.

ON THE TEACHING OF ANATOMY

About 1763 there appeared a certain young man, named Dr. William Shippen, who tried to teach a few loyal followers something about human anatomy. It appears, however, that his teaching of anatomy was periled considerably by some Philadelphia citizens, who demanded that he stop disgracing God and nature by making autopsies on human beings. The good doctor took no heed of these protests, with the result that he was very nearly lynched. If he had not been protected by a friend he might not have continued his work and never have achieved the fame which later was his. The wrath of the people at times knew no bounds. When Cotton Mather and Dr. Zabdiel Boylston had completed their inoculation experiments, they were threatened and openly attacked. Sometimes the doctors had to make all their calls at night, and they always were on their guard against attacks. Doctor Shippen was forced to dig up graves in order to obtain subjects for his work on anatomy. Boylston secretly practiced inoculation experiments on his negro servants and immediate family.

INOCULATION EXPERIMENTS OF ZABDIEL BOYLSTON

Here it should be noted that Boylston was considerably ahead of the English physician, Edward Jenner, who is generally credited with having introduced vaccination for smallpox. Jenner makes no reference to Boylston or Mather in his paper entitled "Vaccination Against Smallpox," published in 1798, although he may have done so in his first paper, written in 1796, which was never published. Nevertheless, Boylston was later recognized for his work on vaccination in Jenner's country, for he was introduced to the Court and made a Fellow of the Royal Society. It is of further interest that Boylston was a cousin of Cotton Mather's, and it was Mather who suggested to Boylston to try vaccination for smallpox. Mather, in turn, got the idea while browsing through English literature, where he found that vaccination was practiced extensively in Turkey during the Crusades. Thus, it seems clear that the colonists and their physicians were not lacking in powers of actual observation and appreciation of significant phenomena for good health and protection of their people. In fact, they were more alert and progressive than were their colleagues abroad, who were more advantageously situated, but their rewards were pitifully small.

FINANCIAL REMUNERATIONS

It may be of interest to consider briefly the remuneration that these early doctors received for their professional services. The case of Dr. James Oliver, practitioner of "physic," is interesting in this connection. It seems that Doctor Oliver charged only modest sums for his medicines and visits. It is pathetic to find that the good doctor often had no money for making visits, for patients paid little or nothing. For instance, one J. Hancock paid Doctor Oliver, but the doctor received "no pounds, no shillings, and sixpence." Although Doctor Oliver often attended as many as twenty or thirty patients daily, and more during epidemics, he received the total sum of only seven pounds and two shillings, or something over $35, for all his work. Truly, the life of the colonial doctor was far from the proverbial bed of roses, and his practice was anything but lucrative. Perhaps some of the colonial doctors never received their just dues because of the unpalatable medicinal concoctions which they prescribed for their patients. In fact, these mixtures were often so revolting to take that the patients were forced to expectorate them and, therefore, no good came of them. The treatment seemed worse than the disease, and the patient recognized that he recovered without the doctor's medicine and thus denied the value of medical services. To make matters worse for the colonial doctors, there was the competition from midwives, who, in a way, were better appreciated because of their personal services.

INFLUENCE OF MIDWIVES

It may be reasonably doubted if midwives should be classed professionally with medical practitioners. However, by the middle of the seventeenth century they were regarded as being equally important and, therefore, they may be considered here. The other two classes of practitioners were physicians and surgeons. In any event, the midwives considerably affected the lives of the colonists and the work of the early physicians. During childbirth, no female patient was allowed to be attended by men. As a result, midwives were expected to take care of the mother as well as the child. Some of these midwives, among whom one of the most outstanding was Mrs. Ann Hutchinson, who founded a colony in Rhode Island, were highly proficient in this trade, and made it the sole business of their lives. The great class of midwives was built up and reigned supreme in obstetrics during the seventeenth and eighteenth centuries. Their extinction resulted only in the latter part of the eighteenth and the middle of the nineteenth centuries, when it was found that they often carried the germs of the dreaded puerperal fever. Undoubtedly their creed was, "let nature do the work." The result of this was that the proportion of children born dead in the Colonies was only a little less than the proportion of children that survived. Oftentimes the midwife was careless, the child was miscarried, and the mother died of puerperal fever. At times, of course, there were factors which could not be controlled or prevented. In one case in particular, when Mrs. Ann Hutchinson was acting as a midwife for a woman, the child born was a monstrosity, and Mrs. Hutchinson was required to appear before a Massachusetts court. She was charged with bewitching the child because she had muttered something before its birth. If she had not escaped to Connecticut, she would have been hanged. Similarly, in the early histories of Virginia, New York and New Jersey, midwives were often persecuted for something which they could not help or control. Again, the crude practices of these midwives make one wonder that the colonists survived as well as they did.

The important thing to note here is that the midwives, though often uneducated and generally untrained in the medical work they were doing, nevertheless played an important part in the lives of the colonists. They also constituted a fair percentage of the population, and were always in demand. So far as the colonists were concerned, the midwives were on the same plane as physicians and surgeons, despite their lack of learning. However, they contributed nothing real or lasting to medicine proper, except possibly their dangerous practices, which gradually caused the people to turn to the physicians. According to Mumford, one of the first male physicians to attend a woman during childbirth was a man from the Colonies. His name is not given by Mumford, but he points out that the physicians of these small settlements were wise enough to teach the people the importance of a physician taking care of the mother as a patient. In this respect, they were at least even with, if not somewhat ahead of, the doctors of the mother country. England had not yet entertained the thought of banishing midwives, but the colonists had dropped them as a class. Not only did the colonists lead in this regard, but also in the practice of medicine proper. They were discarding most of the ineffective remedies of the old formularies, and in their place were substituting more desirable and effective drugs.

COLONIAL FOUNDATIONS

A prominent American physician has said that the physicians of the continental colonies were among the leaders in medicine of the world during the seventeenth century, and it is not difficult to agree with him. There is much evidence of a real scientific interest among the colonial physicians, and, if it had been properly sustained, American medicine would have progressed faster and farther. As it happened, there was stagnation for more than seventy-five years after the colonists, and a domination by a spirit of commercialism until about forty years ago, when medicine in this country was again gripped by a scientific spirit which continues with increasing importance.

Looking back at those early times, it seems fair to conclude that by the time of the American Revolution, medicine in the continental colonies had a pretty fair foundation upon which could be laid the cornerstone of modern American medicine. We owe a great deal to these colonists and their physicians, who came here unprepared generally for diseases, many of which were new to them. Through their own ingenuity, and adaptations from various sources, they worked out methods for successfully combating and controlling the maladies. As already indicated, the colonists had to be more practical because they had few medical books or guides from England, and those that came were often out of date. The colonists, therefore, had to start by making first-hand observations on patients, and then, with the help of some Indian, old English concoctions, and of a few of their own, they gradually ruled out valueless cures and treatments. Many of these were, unquestionably, primitive. However, these and more may be legitimately excused, as well as praying over inveterate maladies attributed to demoniacal possession and other questionable methods, which today would cause amazement. These people may be excused, because they learned from first-hand experiences, by a sort of trial-and-error method. Of course, many times the patients got well because they had been helped by nature, rather than by the treatment. Be that as it may, the colonial physicians were conscientious, ever alert, practical men, who sought—and many times in vain—to save their friends, neighbors, and relatives from the clutches of death. They were humanitarians and more.

In reviewing the achievements of the seventeenth and early eighteenth centuries, there is to be found a long list of honored names, and a precious record written in private memoirs, in public charities, and in permanent contributions to medical science. Through their earnest endeavors, our predecessors, the colonial physicians, were among the leading, and in some things *the* leading, medical practitioners and investigators of these centuries. Because of the basic interests held by these old colonial practitioners, many of whom were also preachers, blacksmiths, and other tradesmen, American medicine has been built up to the highest degree of efficiency of all nations. It has become highly specialized to suit the needs of the many diseases now known, and of conditions which have developed with time. However, much of this is due to the firm and original foundations, especially the will for self-improvement, passed on to us by those old colonial practitioners.

The founding of the following important institutions and organizations in their time will bear witness to the colonists' great foresight and wisdom: The first hospital in Long Island (1663), College of William and Mary (1693), Yale College (1701), the Philadelphia Hospital (1721), the Medical Society of New York (1749), Columbia University (1756), University of Pennsylvania Medical School (1765), the first medical school in this country, Columbia Medical School (1768), Princeton College (1776), the first American pharmacopeia published by William Brown in Philadelphia (1778), Harvard College (1636) and Harvard Medical School (1782). In 1799 Congress passed the first quarantine act. Attempts at state regulation of medical practice were begun in New York in 1760, and in New Jersey in 1772; some kind of control also being exercised in Massachusetts and New Hampshire in 1781. In that early era of our country, that student of medicine and immortal surgeon, Dr. John Collins Warren, came into the world (1778), a man who will always be remembered for making, in 1846, the first completely painless surgical operation with ether anesthesia at the Massachusetts General Hospital.

Thus, everything considered, the continental colonists and their physicians were not only not lacking in appreciation of the great medical discoveries and developments in the Old World, but they actually began and made many of their own. They laid the foundations for great institutions and opportunities in this country, and these same institutions and influences have continued to expand and develop down to the present day. All this testifies to the remarkable wisdom and foresight of these colonists. Indeed they builded more and better than they realized. For today, American medicine leads all countries of the world in its high achievements, discoveries, and devotions to the public health and welfare. These colonial contributions in medicine† must be regarded as of the first order, for the seeds of some of them have given richly deserved harvests. They have affected institutions and teachings of medicine not only in this country, but throughout the world. Hence, it can be said truly that American colonial medicine made a real, substantial, and lasting contribution to all populations, in all countries, and for all time.

CLINICAL NOTES AND CASE REPORTS

A SELF-RELEASED LOCK-BOLT FOR FRACTURES OF THE FEMORAL NECK*

By E. W. Cleary, M.D.
and
Gordon M. Morrison, M.D.
San Francisco

A DEVICE which locks into the head fragment so firmly that the reduced fractured surfaces of the neck may be impacted securely and permanently together, is much to be desired.

One of the writers, Doctor Morrison, has invented a device which has proved so satisfactory that this preliminary report is in order.

This instrument is a hollow bolt of stainless steel, three and one-half inches long and one-quarter inch in diameter. The penetrating end has a slot three-quarters inch long and one-eighth inch wide, holding two levers hinged on a single cross-pin. While the bolt is being inserted, these locking levers lie completely within the slot. When the bolt is in place, the locking levers are pushed out by a threaded pin one-eighth inch in diameter, which traverses the hollow in the bolt to a position transverse to the long axis of the bolt. The protruding end of this pin has a knob by which it may be easily turned. The protruding end of the bolt is fitted with a loose-fitting nut. When the lock levers are out, and this nut is turned up tight against the cortex, the reduced surfaces are held so firmly together that no cast, splint or other external fixation appliance is necessary. The patient may be freely turned in bed, and may be

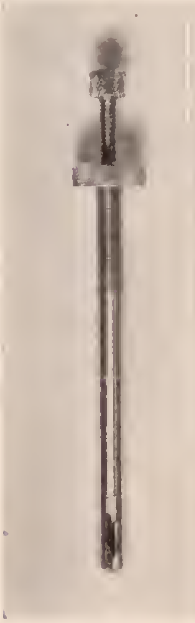

Fig. 1a

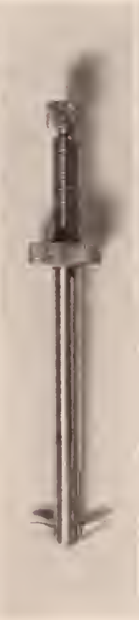

Fig. 1b

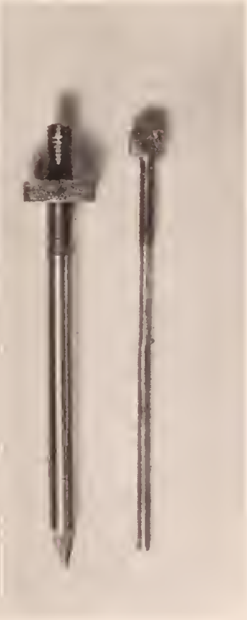

Fig. 1c

Fig. 1a.—Showing slotted end with levers folded within slot. Bolt is inserted in this position.

Fig. 1b.—Bolt with internal member screwed down, which forces levers out of shaft and locks them in a transverse position.

Fig. 1c.—Internal member has been withdrawn. The levers are folded over the end of the bolt, as in extraction of bolt.

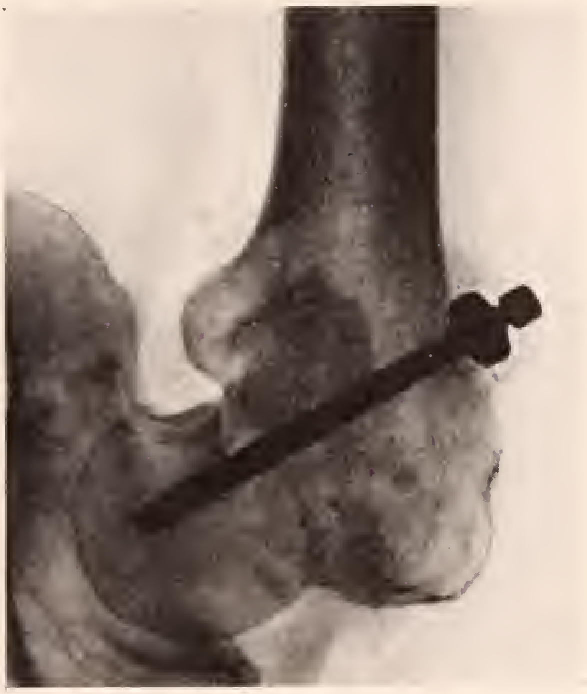

Fig. 2 (Case O. W.).—Bolt transfixing femoral neck. Transverse members are not seen, as they are in the A. P. plane.

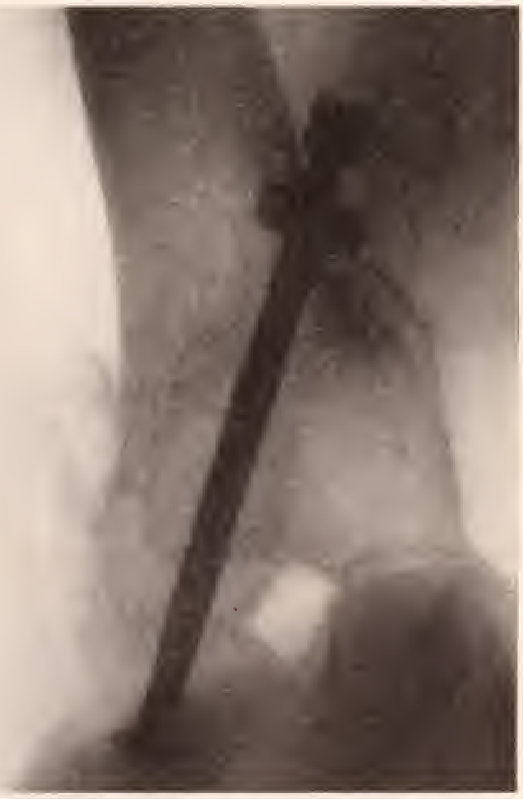

Fig. 3 (Case O. W.).—Lateral, showing bolt in femoral neck with levers in transverse position. (The apparent bending of the bolt is caused by the use of a curved cassette in taking this picture.)

gotten up on crutches as soon as the wound has healed.

When the bolt is to be withdrawn, the center pin is unscrewed and the locking levers rotate back beyond the end of the bolt and flush with its surface, thus offering no possible obstacle to withdrawal.

Our procedure is to reduce the fracture under local anesthesia by Leadbetter's maneuver, check reduction by heel-palm test, and confirm by A-P and lateral x-rays. These are taken with four Michel clips, so placed in the skin about the hip that the clips and their shadows in the x-rays enable us to aim the one-quarter inch drill used to make way for the lock-bolt. We expose the trochanter for the drill under local anesthesia. X-rays check the position of the drill, which is withdrawn and the bolt immediately inserted. The bolt is locked and tightened as above described.

DOUBLE UTERUS WITH FEATURES OF SPECIAL INTEREST

REPORT OF CASE

By Carl H. Talmage, M.D.
Sanitarium

The case of double uterus here reported represents failure of fusion of the Mullerian ducts from the pelvic outlet upward, associated with partial obstruction of the introitus. It is remarkable that the patient was not aware of any pelvic abnormality, though she had been married for eleven years.

Another feature is the development of fibromyomata in both uteri, with resultant pressure symptoms. The anatomical features are similar to the case reported by Dr. Joseph B. De Lee, except that bilateral fibromyoma were present instead of a pregnancy.

REPORT OF CASE

Mrs. F. H. R., white, age forty-three. The family history was irrelevant. The patient had the usual diseases of childhood, and has since had the following: alveolar abscess, renal calculus, aet. thirty-one. She had tonsillectomy and thyroidectomy.

Menstruation began at twelve. She had regular periods of three to five days' duration, with twenty-eight-day interval. The flow has become more profuse in recent years, without associated pain or headache. During the past year, menstruation is described as very profuse and followed by weakness and pallor.

She was married at the age of thirty-two. Due to fear of childbirth, and a desire to lead an active life outside her home, she had abstained entirely from sexual relations and, consequently, there have been no pregnancies.

Generalized abdominal pain, associated with distention and excessive amounts of gas, came on one month previous to admission. This was most severe two to five hours after meals, and also kept her awake at night. Fasting and the use of enemas gave a degree of relief, and she had fasted three days when she was admitted. There had been swelling of the ankles, which started at the age of sixteen, and this swelling was more marked in recent years. Recently she has slept with the foot of her bed elevated to reduce the swelling. Pain and stiffness of joints of fingers had been noted. Nocturia once had become a usual occurrence.

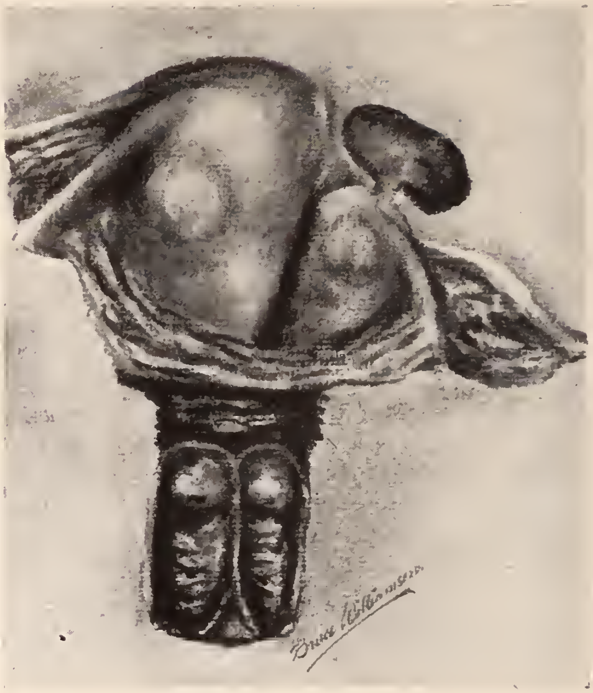

Fig. 1.—Diagrammatic drawing showing anatomic features and relationships.

Examination showed a pale but well-nourished white female. There is a transverse scar on the neck. The findings of the heart and lungs were essentially normal. Blood pressure was 130/75. Upper abdominal findings were normal, but there was hyperesthesia and resistance in the lower abdomen, which was more marked on the right. A mass seven centimeters across could be felt in the lower right quadrant. There was puffiness of the ankles. No swelling of the joints of fingers could be detected. Vaginal examination was unsuccessful, because the introitus was so small that one finger could not be introduced without pain. No other abnormality of the external genitalia was noted at this time. Bimanual examination was done with the finger in the rectum. A mass was outlined to the left which was interpreted to be the uterus displaced to that side. On the right was a larger mass, which was quite hard. There was no induration of tissues, but the masses palpated were firm and irregular. It was not determined whether the two masses were attached or separate.

Blood count was reported as follows: Hemoglobin, 50 per cent; red cells, 3,380,000; white cells, 5,800. The differential showed a lymphocytosis. The urine findings were normal.

Operation.—The patient entered the hospital August 12, 1935, and laparotomy was performed the following day. Midline incision above the pubis was made, and exploration revealed a large uterus lying in the right side of the pelvis. On the left another enlarged uterus with fibroid pedunculated from the fundus was found. The uteri were not united above the cervix, and a strip of peritoneum passed from the bladder to the cul-de-sac between them. Each uterus had one round ligament, and one fallopian tube with normal ovaries in relation to the tubes.

The procedure consisted of removal of the fibroid from the left uterus to improve exposure, followed by removal of that uterus, leaving the cervix *in situ*. The large uterus on the right was next removed, leaving the cervix. Fallopian tubes and ovaries were left in both sides. After careful ligation of uterine and ovarian vessels, the round ligaments were sutured into the stump of the cervix on each side, and the bladder fold of peritoneum was sutured over the raw areas. Appendectomy was done, after which the abdomen was closed by my usual technique. Permission to do plastic on the introitus had been denied, so it was not done at this time.

Permission was subsequently obtained, and on August 20 examination and plastic procedure were carried out. Two openings were found inside the labia minora, with a vertical septum between them. The opening on the right would admit the tip of the finger, but the left was smaller. The hymen was not ruptured. The openings were enlarged, and the septum was found to extend the entire length of the vagina, and a small virgin cervix was found at the apex of each vagina. The septum was severed between clamps, and sutures were placed to prevent bleeding.

The pathologist reported that the right uterus measured 11 x 12 x 9 centimeters and weighed 454 grams. The left uterus measured 7.5 x 7 x 5 centimeters and, together with the pedunculated fibromyoma, weighed 220 grams. The pedunculated fibromyoma measured 8 x 5.5 x 5 centimeters and weighed 94 grams. Numerous other fibromyoma were found in both uteri; the largest one measured eight centimeters in diameter.

The patient had an uneventful convalescence. Examination four months later revealed satisfactory healing. The vagina admitted two fingers and is of normal depth. Satisfactory coitus was reported. Blood count was near normal.

FUNDAMENTAL PRINCIPLES IN FRACTURE SURGERY

By H. W. Spiers, M.D.
Los Angeles

THE treatment of fractures in recent years has been assuming more and more the center of the surgical stage. The x-ray spotlight is focused on the fracture surgeon. The age of high-speed transportation for rich and poor alike is producing an ever-increasing number of serious fracture problems. It behooves even those who see these cases only occasionally to be prepared in the essentials of successful treatment.

There seem to be four fundamental principles in the treatment of all fractures. They are:

1. Reduce by traction and countertraction.
2. Place the distal fragment in line with the proximal fragment.
3. Immobilize until firm union takes place.
4. Immobilize the joints proximal and distal to the site of the fracture.

Proper consideration and coördination of these principles will, in the large majority of cases, keep the fracture surgeon on the high road to success.

Nature's invariable and involuntary response to bony structural damage is muscle spasm. It is nature's method of splinting the part. Overriding and malalignment is due to, in a large part, and maintained by, muscle spasm. There are several ways of overcoming muscle spasm:

(*a*) Anesthesia—general, spinal, block, or local.
(*b*) Temporary traction by hand, by traction tables, frames, and the like.
(*c*) Continuous traction—skin or skeletal.

To correct overriding of the fragments, traction and countertraction with, or without the assistance of anesthesia, would seem to be and is a mechanical necessity. The distal fragment must be pulled by the fixed proximal one until the normal length is restored.

The distal fragment should be placed in line with the proximal one. Proper alignment is mechanically essential if the part is to be restored functionally unimpaired. A study of fractures will soon convince one that the proximal fragment, attached to its fulcrum, is still a lever responsive to certain, though changed, muscle-pulls. In general, it assumes a fairly fixed position. The position of this fragment is not readily changed. On the other hand, the distal fragment is the free one in most instances. It is readily manipulated and aligned. Therefore, the second fundamental principle requires consideration in proper treatment. End-to-end apposition of fragments is not necessarily essential to a satisfactory functional or cosmetic result, but it is desirable. Alignment is essential. Variation from normal alignment of the shaft of a bone always means mechanically defective function. Malalignment of the crankshaft of your automobile means bearing trouble promptly. The same applies to the extremities or the trunk. This is particularly true of the lower weight-bearing extremity. This principle is being more and more evaluated in the care of fractures of the spine. Restore the normal curves, and normal function will be more surely restored.

The sequence of events that takes place in establishing bony union is quite definitely known. Disturbance of this sequence seems, to a degree, to be resented by nature. Injudicious mobilization of fractures during the early stages of union is, in too large a number of cases, responsible for the delayed and nonunions increasingly seen. The fracture site must be immobile until firm union takes place. The third fundamental principle requires careful consideration in the plan of treatment.

Fixation of the joints proximal and distal to the fracture site, in general, is a mechanical necessity. If one fragment is free to move, immobilization and alignment requirements are violated. Special instances, as Colles's fractures and the like, allow violation of this fourth fundamental. It is largely applicable in fixation by splints, braces, casts, and the like. Certain traction methods allow for function of one or both of the proximal and distal joints, but they must be considered a special and exceptional method, and thought of as such.

A word about the plan of treatment: To no small extent does the successful treatment of a fracture depend upon the plan as outlined at the beginning. In general there are many ways of handling each fracture problem. Certain serious fractures must be hospitalized. Some require recumbency. Others can be made ambulatory. Often a patient must be protected against himself, thus requiring "foolproof" care. The social, economic, and many other factors require consideration. Once a plan has been laid out, follow it through until its inadequacy has been proved. Often complications require a change, but with the change see that a new, well-thought-out plan is established.

In conclusion: It is well to think through each fracture problem and plan its treatment in accord with the fundamental principles in the care of all fractures if an ultimate high percentage of success is to be obtained.

2007 Wilshire Boulevard.

BEDSIDE MEDICINE FOR BEDSIDE DOCTORS

An Open Forum for brief discussions of the workaday problems of the bedside doctor. Suggestions of subjects for discussions invited.

SCARLET FEVER

I. ETIOLOGY AND DIAGNOSIS

E. B. Shaw, M.D. (384 Post Street, San Francisco).—*Etiology.*—Although the etiologic relationship of the hemolytic streptococcus to scarlet fever has been almost indisputably established, the problems entailed in diagnosis and treatment have thereby not been notably simplified. There are so many differences of opinion regarding the significance of bacteriologic and immunologic studies of the disease that it is a difficult matter for the clinician to apply with complete consistency all of these laboratory observations to the management of the disease.

A great many strains of the hemolytic streptococcus may be productive of the syndrome called scarlet fever. These strains vary widely in their biologic and immunologic characteristics, and the only property which they possess in common is their capacity to produce a soluble toxin capable of inciting the characteristic rash of the disease. This rash-producing toxin may best be identified by a skin test performed with a filtrate of a suitably prepared and diluted broth culture of the streptococcus isolated from infected patients. When this toxic filtrate is injected intracutaneously into susceptible human subjects, a characteristic skin reaction, the equivalent of the Dick test, is produced in twenty-two to twenty-six hours. To what extent this rash-producing toxin is responsible for all of the clinical manifestations of scarlet fever is at present uncertain, although there is reasonable evidence that many of these symptoms are incited by this toxin. Not only are different strains of streptococci concerned with the pathogenesis, but at least two distinct toxins have been identified in different cases of the disease.

No matter what importance we may ascribe to the soluble toxin in the pathogenesis, too close a parallel must not be drawn between scarlet fever and a disease such as diphtheria, which is due almost entirely to the activity of an exotoxin. The diphtheria bacillus behaves within the body almost purely as a saprophyte, exerting nearly all of its disease-producing activity by means of a soluble toxin. The hemolytic streptococcus, on the other hand, is capable of a far greater degree of parasitism than the diphtheria bacillus; and although certain effects are unquestionably due to its soluble exotoxin, it is able to produce a far greater degree of locally destructive and invasive activity. The diphtheria bacillus exerts little or no pathogenic activity upon a patient demonstrably immune to its soluble toxin, as shown by a negative Schick or Kellogg test. Innumerable clinical experiences, however, illustrate that a patient who is naturally immune, or has been immunized artificially or by means of active disease against the rash-producing toxin of the scarlet fever streptococcus (demonstrated by means of a negative Dick test) may be infected by streptococci acquired through scarlet fever exposure, the resultant disease often being no less severe in course, complications, and sequelae than scarlet fever, lacking only the diagnostically significant rash.

The attempt to apply bacteriologic information to the problem of diagnosis is equally difficult. The hemolytic streptococcus may be demonstrated in nearly every case of scarlet fever if cultural studies are carefully carried out, and it is possible, although impractical, to demonstrate that these cultures will produce the characteristic toxin. The persistent absence of hemolytic streptococci from the local infectious focus, which is usually the throat, in a patient suspected of having scarlet fever, has some weight against the diagnosis; but if one attempts to utilize positive cultures as evidence in favor of the diagnosis, he is immediately confronted with the fact that a great many patients, showing little evidence to support a clinical diagnosis of scarlet fever, will also yield cultures of hemolytic streptococci, which are indistinguishable from scarlet fever strains. Not infrequently, in institution or family epidemics, numerous patients will develop throat infections, among whom only a few may develop the rash and full-blown characteristics of scarlet fever; these latter will sometimes not be those most seriously ill. A positive diagnosis of scarlet fever can be made only on clinical evidences, and not on the basis of bacteriologic findings. The public health significance of positive bacteriologic findings during epidemics is obviously another matter, and is most difficult of satisfactory solution.

Diagnostic Features of Scarlet Fever.—The diagnostic features of typical scarlet fever scarcely need be enumerated. Most commonly the first symptoms appear within a very few days after exposure, when the patient develops signs of severe tonsillitis or pharyngitis. The absence of tonsils is far from complete protection against scarlet fever. The precise symptoms of onset are of little critical significance; there is slight to extreme elevation of temperature and pulse, accompanied by varying degrees of prostration. The original throat infection is often severe in character, there is much swelling, redness, and exudation of the local tissues. The rash usually appears within twenty-four hours, as a blush resembling sunburn, which rapidly spreads over the chest, abdomen, and back, being particularly marked on the lateral aspects of the body, and in the folds of the axilla and the groin. The rash may be most evanescent in character, but typically persists from four to seven days, becoming, meanwhile, somewhat more papular and elevated in character. The face, especially the circumoral region, is usually free from rash, and over the skin of the neck and of the extremities the rash is more scattered and somewhat more papular in character. Not uncommonly the papillae of the skin of the dorsal aspects of the distal phalanges of the fingers and between the eyebrows become distinctly prominent. During the next few days, changes in the coating of the tongue and enlargement of the lingual papillae characteristically produce at first the strawberry, and then the raspberry appearance. General lymphadenopathy commonly occurs. There is typically deepening of the pigmentation in the skin folds of the body, particularly at the bend of the elbow. Increase in fragility of the capillaries is readily demonstrable by the application of a tourniquet about the arm. The rash fades with varying degrees of rapidity, and is usually succeeded by some desquamation which begins in the groin and axillae and is most typical during the third week in those cases in which there is pronounced exfoliation of the skin of the fingers and toes. In many typical cases, desquamation is not marked or seemingly does not occur, and although typical desquamation is strongly positive evidence for the diagnosis, its absence is of little value as against the diagnosis.

The diagnosis of classical scarlet fever presents little difficulty, and seldom requires other than clinical evidences to establish. The disease differs from measles, German measles, and others of the exanthemata far more than it resembles them, and differentiation is of little practical difficulty. Drug reactions, particularly those due to arsenicals and the barbiturates, are sometimes productive of scarlatiniform eruptions which are best differentiated on the basis of history and the absence of evidences of local streptococcus infection.

The greatest diagnostic problem is presented by patients in whom the entire disease is very mild and with atypical rashes accompanying either mild or severe local infections. In these cases the diagnosis must rest almost entirely on clinical grounds, although the persistent absence of hemolytic streptococci in cultures is against the diagnosis. The physician should take care that his mistakes be made in the direction of safety, and should be prepared to make a positive diagnosis in the presence of only a few positive signs, never insisting that the clinical picture be present in its entirety. It is especially important that the diagnosis be made early, for at this time symptoms and signs will almost surely be more suggestive than later; moreover it is this stage at which communicability is greatest. In the presence of throat infections and a scarlatiniform rash, the burden of proof should be that the disease in question is *not* scarlet, and this diagnosis should be discarded only if a positive alternative diagnosis can be made.

Duke-Filatow's disease (Fourth disease) has been differentiated as a separate exanthem with many of the characteristics of scarlet fever, in which only a mild infectious course is observed. One should be most suspicious of the clinical criteria for this diagnosis; it should seldom (and I think never) be made, and is untenable unless hemolytic streptococci are consistently absent from cultures. Scarlatiniform eruptions accompany hemolytic streptococcus infections not only of the throat, but also those of the middle ear, of the accessory air passages (in which a curiously protracted "prodromal" stage and a virulent course are sometimes seen), of infected wounds anywhere in the body, of infected cutaneous burns, and of infections of the uterus after delivery. If one admits the etiologic connection between the hemolytic streptococcus and the eruption of scarlet fever, all of these cases should be regarded as scarlet and cared for with proper regard to isolation. It should be remembered, however, that there is a greater likelihood of dissemination of infected mouth and nasal secretions than of infected discharges from these other foci. It should be particularly borne in mind that following scarlet fever, purulent discharge from ears, nose, suppurating glands, or any other focus, are infectious as long as they may persist, and quarantine should be accordingly protracted. The causative organism may persist in the pharynx for a much longer period than the usual quarantine period of three weeks. As the local infection subsides, the opportunity for the dissemination of an infective dose of streptococci is greatly diminished and the present length of quarantine is, therefore, practically adequate. Certainly insistence on negative cultures prior to release from quarantine would prolong this period interminably in many cases, and seems unnecessary on the basis of clinical experience. If negative cultures were required for release it would raise the embarrassing problem of what should be done with the many healthy individuals who carry hemolytic streptococci in their throats, or with the many patients who have hemolytic streptococcus throat infections without other evidences of scarlet fever. It does seem desirable, however, that the physician exercise some control, with respect to the public health, over those patients known to have been exposed to scarlet fever who have developed throat infections without rash, although it is most difficult to maintain an absolute quarantine for these patients.

Certain skin reactions have been proposed as of practical aid in diagnosis. (1) Patients who have scarlet fever should have had a positive (susceptible) Dick reaction prior to attack, and during the early stages of the disease. The Dick reaction will usually become negative as the disease progresses to recovery. There is, however, considerable variation in this orderly sequence of events. The Dick reaction is more difficult of precise interpretation than the Schick reaction and, possibly for this reason alone, is distinctly less reliable. Clinically indisputable scarlet fever has been known to occur in those with previously negative Dick reactions. (2) The Schultz-Charlton reaction depends on the ability of convalescent serum or the serum of immunized horses, to neutralize the rash-producing toxin. Such a serum injected intracutaneously into a heavily erupted area during the early stage of the rash will produce a locally persistent area of blanching. This reaction has some diagnostic significance but is of little practical value, inasmuch as blanching is best produced in typical eruptions and is hardly demonstrable in scattered atypical rashes where it would be of critical value. The utility of this test is further complicated by the fact that in using an immune horse serum for the blanching reaction, a zone of erythema may be produced by the serum which will obscure the blanching; furthermore, unpleasant manifestations of serum disease may be produced by even this small dose of horse serum.

* * *

II. SYMPTOMS AND PROGNOSIS

Albert G. Bower, M. D. (136 North Central Avenue, Glendale). — *Symptoms.* — This disease shows most variation in its manifestations of any of the common exanthemata. While usually occurring within two to four days after a single known contact, its incubation period is erroneously believed to be much longer, probably because non-immune persons incurring more or less constant exposure in quarantined households are often bebelieved to be incubating the disease before the actual infection finally results. However, the incubation period may at times be longer.

The disease must be classified clinically according to its symptoms if we are to have a clear understanding of its clinical, therapeutic, and public health aspects. It may be classified on a purely clinical basis into three types: ordinary or simple; septic or scarlatina anginosa; and toxic, malignant, or hemorrhagic scarlet fever. After the particular type is clinically established, it may again be roughly subdivided into mild, moderately severe, or severe. Naturally, in such a protean disease, there will arise at times an overlapping of symptoms that causes some difficulty in establishing a clean-cut differentiation concerning the classification of an individual case. Fortunately, this is not usually the case. In over a thousand cases observed in Southern California during the past year, it was rather easy to place over 95 per cent under the heading of simple. The septic case, while relatively rare, is next in number to the simple, while in this state, the toxic variety is very rare. The emphasis attached to classification is due to the fact that it furnishes the logical key to rational treatment. In few places in the temperate zone, is scarlatina as relatively mild as it is in California, and particularly in Southern California. Climate appears to exercise a moderating influence, as contrasted with other parts of the country with more vigorous changes in season.

Attention is invited to the danger, from a public health standpoint, of the very mild or abortive cases of the simple form, which are accompanied by the mildest of evanescent sore throats and ephemeral rashes in which a physician is rarely called, and which usually escape quarantine to spread the disease among susceptible contacts, who generally do not escape so lightly. With this exception, little will be said about the symptoms of the simple type. All physicians are familiar with the sudden prodromal invasion, the vomiting, the anorexia, the hot, dry skin, the smart rise in temperature, the malaise, the circumoral pallor with flushed cheek, the coated tongue, and the occasional headache, chill, or convulsion in smaller children. Cough is uncommon. The severity of these invasion symptoms may be used as a fairly accurate gauge as to the severity of the ensuing eruptive stage, which commonly follows in twenty-four hours. The rash usually occurs on the chest and spreads over the entire body within a day. It lasts from a few hours to a week or longer, but is usually fading rapidly at the end of three or four days. The rash on the palate and tonsils, and the strawberry or raspberry tongue usually complete the picture. The pulse is high and this persists until the rash fades. The fever averages 103 degrees. In the uncomplicated case the patient improves in well-being with the appearance of the rash. While commonly described as an erythema, with the exception of the face, a careful scrutiny of a typical scarlet fever rash discloses that early it consists of miliary punctate macules, which later become papular, vesiculate, and frequently pustulate. In the first phase the skin feels hot and velvety; later it affords a "goose flesh" sensation. Pastia's lines appear in the folds of the elbow. Skin tests are unreliable in establishing the diagnosis. A leukocytosis of 10,000 or more is usually present.

With the subsistence of the rash, the desquamative stage ensues about the eighth to the tenth day. It may be limited to a few branny scales at the ends of the digits and on the hands and soles, or less frequently may involve all of the epithelial structures of the body. It may last only a few days, or continue for two months, but averages two weeks. The treatment of this form of disease is entirely symptomatic and supportive.

In the septic variety, all symptoms are exaggerated. The patient is terribly sick, and septic from the onset. Fever is high, often ranging from 103 to 107, and is of the fluctuating septic type. Attention is early invited to the exceedingly severe throat symptoms with thick, leathery greyish streptococcus membranes, which may extend to the nares or down to the trachea, and may only be distinguished from diphtheria by smear and culture. This type of the disease is practically nonexistent in individuals who have had a tonsillectomy. All the various stages in the unsuccessfully treated cases persist longer and are more severe, provided the patient survive. The throat remains sore longer. The sinuses and middle ear are early involved. The glands swell rapidly, and may suppurate. Purulent discharge from the nose is common. Extension from the involved middle ear to cause mastoditis is not unusual. Albumin, casts, and red blood cells are commonly present in the urine. The course of this type is uninfluenced by scarlet fever antitoxin, but the result of adequate immunotransfusion from a compatible convalescent donor, or of intravenously administered pooled, convalescent scarlet fever, human serum, is often one of the most gratifying and spectacular sights one may be permitted to see.

The malignant or toxic variety is, fortunately, most uncommon with us. Onset is exceedingly severe, and is ushered in by convulsion and hyperpyrexia, or by sudden chill. The rash is hemorrhagic or purpuric in tendency. The nervous system is profoundly involved from the onset, and if the patient survive, there is a rapid tendency to enter the syndrome known as the typhoid state, with delirium, coma vigil, and carpholgia. Hematuria occurs early. The tendency to unusual throat, ear, and upper respiratory involvement is absent. The picture is one of overwhelming toxemia, and the treatment should include the use of properly administered antitoxin, the result of which is often as spectacular here, as it is disappointing in septic and simple types. In fact, in the simple type, the urticaria produced by use of antitoxin is usually as bad, or worse than the disease.

In the days of pre-aseptic surgery, scarlet fever originating from wounds was a well-recognized clinical entity. In observing several thousand cases, about the only survival of this type we have seen is that complicating septic abortion. In these cases, pooled convalescent serum and commercial strepcococcus antiserum have been of great benefit, the antitoxin disappointing.

Among the commoner complicating symptoms of scarlet fever, in general, may be mentioned those ascribed to nephritis, otitis media, and mastoiditis, severe cervical adenitis, sinusitis, arthritis, endocarditis, and occasionally sinus thrombosis, brain abscess, and chorea.

Prognosis.—The chances of recovery or death in this community vary with the type of the disease and with the severity of the type. All toxic cases present a bad prognosis, if not treated early. All septic cases of any severity present a guarded prognosis, because of the ear and sinus complications, as well as those of the kidney. The prognosis in the common type, except in its severest form, is usually very good, bad prognostic omens being due almost entirely to complications involving the ear, nose, or throat. During the past year, in over a thousand cases hospitalized the total death rate in all types was just under two per cent. Very high white counts, 50,000 or over, are of bad portent. In late years the death rate has tended to show a steady decline, being highest during the coldest weather. Scarlet fever, as commonly seen, is most dangerous in infants under one year, and the majority of deaths occur in children under six years. It is extremely fatal to the few old people who take it.

Among unfavorable factors may be listed: severe membranous sore throat, cutaneous or internal hemorrhage, nephritis, mastoiditis, and sinus thrombosis.

* * *

III. TREATMENT

Edward J. Lamb, M.D. (1515 State Street, Santa Barbara.)—*Preventive Treatment.*—Hospitalization is no doubt the most reliable method to check the spread of this disease. Home care cannot be credited with the necessary technique to prevent its spread. In the home care of a scarlet fever patient, the nurse and attending physician should use as careful technique as possible; a gown should be worn in the sick room, the hands should be washed in 4 per cent lysol solution and rinsed in 50 per cent alcohol solution. Eating utensils should be segregated and boiled. Discharge from mouth, throat, etc., should be immediately burned. Quarantine should be instituted as long as there is any discharge from nose, throat, mastoid, or suppurating glands, since infection is not from desquamation, but rather from discharge.

Active Immunization.—Most hospitals are immunizing their staff of nurses and internes by an intramuscular injection of diluted toxin. Three injections are given one week apart. In private practice it is not commonly done, the reason being the reaction and the question of the length of the durability to the immunity.

Nursing Care. — As in any acute illness, the patient should be confined to bed in a well-ventilated room. The air should be fresh, but also warm to prevent chilling. Great care should be taken that the patient is at no time exposed to a draft. During the early stages of the disease no bathroom privileges should be allowed. The patient should be kept in bed as flat as possible for at least three weeks. Sponge-baths or cooling lotions, such as calamin lotion, may be applied to the skin for relief of itching.

The diet should be light and fruit juices should be forced. With small children disinclined to drink sufficient fluid, we have found that feeding plain milk chocolate not only adds to the caloric intake and sugar requirement, but also stimulates a thirst for fluids. Weak beef or chicken broth may also be given for precarious appetites. Personally, I feel that this amount of protein in the diet would not be an important factor in the incidence of nephritis. The bowels should be kept active by enemata or mild laxatives.

An ice collar is applied for an extremely red and sore throat. It has been our policy to give no mouth gargles for fear of inciting an otitis media. In case of profuse nasal discharge, continuous warm saline irrigations are most beneficial. Antipyretic medication is of benefit for elevated temperature. Codein may be given for restlessness.

The frequency and severity of serum reaction have limited the use of antitoxin to only those early cases showing a marked toxemia. When given, it is by the intramuscular route.

Scarlet fever convalescent serum may be used to great advantage without severe reaction. The dose is from 20 to 100 cubic centimeters of pooled serum given intravenously; the dose depending on the patient's age and the severity of the disease. This convalescent serum may be repeated daily if necessary. The results in toxic cases have been striking when this serum is given within the first day or two of the disease.

Regarding complications: The treatment of the patient should be with the point of view of preventing complications.

Inspection of the temperature and pulse record will reveal evidence of beginning complications such as otitis media, mastoiditis, adenitis, arthritis, and endocarditis.

Otitis media. Usually demands myringotomy, especially if there is any sign of bulging of the ear drum and an elevated temperature. Persistent purulent discharge from the canal warrants a roentgenogram study to detect the possibility of mastoid involvement.

Daily excursion of temperature from normal to five or six degrees above normal suggests the likelihood of a mastoiditis or sinus thrombosis. Caution should be taken of the possibility of bilateral mastoiditis or bilateral sinus thrombosis. The treatment, of course, is surgical in the hands of a competent surgeon.

Nephritis. A frequent complication, this may be apprehended by daily urinalysis. Nephritis may not occur until the second or third week. Kidney function tests and determination of biochemical values of the blood, as well as objective signs of edema will dictate the type of therapy. The usual non-salt diet, together with active cathartics and hot packs, will promote elimination and conserve kidney function.

Adenitis. In early stages, ice-bag or cold applications. Lugol's solution (Miii, b. i. d.) for five or six days seems to have an alterant effect. If fluctuation occurs, hot compresses, incision, and drainage are indicated.

Myocarditis. Stimulation may be necessary for a weak and rapid pulse. Strychnin, grain 1/200 to grain 1/100, or camphor in oil, is often found valuable.

Endocarditis and pericarditis. The patient should be kept at absolute rest in horizontal position, with ice-bag to precordia. Salicylates may be given by mouth.

Arthritis. Apply olei gaultheria and olive oil, equal parts, to joints and cover with cotton and flannel bandage. If heart is not depressed, salicylates should be given.

Malpractice: Ankylosis of Wrist Following Treatment of Infection.—A nurse, while attending a child afflicted with streptococcic infection of the throat, November 5, 1930, pricked the thumb on her right hand deeply with a pin. Infection of the thumb developed and the defendant, a physician, was consulted. The nurse was removed to a hospital and the hand placed in a hot saline solution to localize the infection, and hot wet compresses were applied. Later, incisions were made and gradual subsidence of swelling and a lowering of the temperature resulted. On November 22 and 23, however, the nurse's hand gave evidence of ankylosis and the defendant applied a banjo splint to put the hand in a position of functioning. A cast was applied around the splint and the forearm. Claiming that a resulting stiffness of her fingers and wrist was due to the defendant's negligent treatment, the nurse brought suit against him. The trial court gave a judgment for the plaintiff, and the defendant appealed to the Supreme Court.

There was a conflict in the evidence, said the Supreme Court, as to whether, in the application of the banjo splint, the defendant retroflexed the hand at an angle of about 90 degrees or at an angle of from 40 to 45 degrees. The plaintiff contended that the defendant had applied to the hand a splint holding the hand in an exaggerated reflexed position; the hand being drawn back at an angle of about 90 degrees, and that the cast was applied around the splint and the forearm so tightly that it interfered with the circulation and with proper drainage. The defendant and the physician who administered the anesthetic prior to the application of the splint testified that the hand was placed in the splint at an angle of from 40 to 45 degrees. Without passing on the evidence, the Supreme Court was compelled to reverse the judgment of the trial court because of the court's refusal to instruct the jury as follows:

> If under the evidence and these instructions you should find in favor of the plaintiff you can only allow her damages for so much of her disability as you believe from the evidence is due solely to the negligence of the defendant, and not for any disability that you may find was due to the infection.

Under the circumstances of the present case, said the court, since the defendant was not responsible or liable for the original injury, but liable only, if at all, for subsequent negligent treatment, those phases should have been carefully separated by instructions in order that the jury might not be allowed to award damages on mere speculation and conjecture.

The hospital record, continued the court, kept in the ordinary course of business was admissible in evidence as an exception to the hearsay rule where the particular entry in question was identified as having been made by a nurse who worked at the hospital and who attended the plaintiff, although the nurse had subsequently left the hospital and her present whereabouts could not be accounted for. An instruction given by the trial court that the jury was not bound by the testimony of expert witnesses was not violative of a constitutional prohibition against judges commenting on the evidence.

For the error committed, the judgment of the trial court was reversed and the cause remanded for a new trial. (*Murgatroyd* v. *Dudley* (Wash.), 50 P. (2d) 1025.) *Medicolegal Abstract, Journal of the American Medical Association.*

Do You Know About the Volta Bureau?—"We consulted several specialists, and all of them confirmed our fears, but none offered any solution of our problem." Thus the mother of a small deaf child wrote to the Volta Bureau. The sentence might be quoted verbatim from many letters written by parents of deaf or hard-of-hearing children, or by hard-of-hearing adults.

The knowledge that deafness is present and that it is incurable comes with the force of a major calamity. It is so crushing in its effect that something positive in the way of help must be offered immediately if the individual is not to spend desperate years in a bewildered effort to adjust himself. The parents of a deaf child must be told that the child can be taught to speak and can be successfully educated, and that this education may be begun at home immediately, even if the child is not more than two years old. The parents of a child whose hearing is only slightly impaired must be given advice as to his adjustment. The hard-of-hearing adult must be told about lip reading, about hearing aids, about social efforts in his behalf.

The Volta Bureau was established for the purpose of furnishing all this information to all who ask for it. Its services are free. Alexander Graham Bell, the son of a hard-of-hearing mother, the husband of a deaf wife, the lifelong friend of everyone handicapped by deafness, used the money received as a prize for inventing the telephone to found the Volta Bureau so that anyone confronting the problems of deafness might be assured of help. Advice is given as to schools and preschool training, lip-reading instruction, hearing aids, social contacts, psychologic difficulties. While the Volta Bureau is not equipped to do employment service, it gives information in regard to the fields of activity that are open to the deaf and the hard-of-hearing.

The *Volta Review*, a magazine for parents and teachers of the deaf and for the hard-of-hearing, is on the reading table of many physicians. Pamphlets dealing with all phases of deafness except medical problems are available to all who ask for them. Lists of such pamphlets and sample copies of the magazine will gladly be sent free of charge. The Volta Bureau is located at 1537 Thirty-fifth Street, N. W., Washington, D. C.

Anybody may have personality. All that is necessary is a quality or a defect sufficient to dominate the mental faculties, which exist in an uncommon form in juxtaposition to the common form of other individuals.—L. Laurent.

CALIFORNIA MEDICAL ASSOCIATION

This department contains official notices, reports of county society proceedings and other information having to do with the State Association and its component county societies. The copy for the department is submitted by the State Association Secretary, to whom communications for this department should be sent. Rosters of State Association officers and committees and of component county societies and affiliated organizations, are printed in the front advertising section on pages 2, 4 and 6. Articles listed under the caption, "This Month's Topics," have been contributed by the Association's Secretary.

ASSOCIATION ACTIVITIES

FALL COUNCIL MEETING

The fall Council meeting which, by by-law provision must be held in the southern part of the State, will convene in the building of the Los Angeles County Medical Association on Saturday and Sunday, September 26-27, 1936.

* * *

INDIVIDUAL EFFORT FAILS

Very few individuals produce to their full capacity by themselves. Fifty, thirty years ago, this statement could be controverted with little difficulty. Today it is an axiom. No matter what position we occupy or what vocation we follow—profession, business, industry, or what not—we are interdependent upon our fellows. The greater our lack of interdependence the greater will be our inability to produce to full capacity. Non-dependence limits our capacity, fetters progress, confines us to a very contracted circle and concludes life with few, if any, worthwhile achievements.

The thinking individual requires no citations to cause him to realize that in order to accomplish the most, the best, and to attain the highest goal, he must depend upon others and upon groups and units of associates engaged in like vocation or professional endeavor. The successful, accomplishing individual, will be found united with his fellow workers and by their help, in his dependency, aid him to attain and scale the higher heights that ever lie on before. That man reaches his maximum of productive capacity.

Physicians, prone to become lone individualists, many times fail to recognize that they could do better, go farther and record capacity producing results, if they would admit dependency and unite with the guild of their profession. Great would be his profit.

Turn back for a moment—the men who stand out in medicine's progress—N. S. Davis, Senn, Osler, Kelly, Halsted, Welch Billings, Vaughan—name any of yesteryear's leaders, and you will find them all engaged in the midst and dependent upon their associates as they assumed and discharged obligations and duties in the ranks and offices of organized medicine. The recognition they received would not have been acquired otherwise.

While it is not possible for all to attain a place in the world or national limelight as did they, the axiom holds true in state and county endeavor and accomplishment. One need to but turn to your own state and county archives for verification.

The point of this comment is, that you are dependent upon your county and state membership affiliation to forge ahead and produce to your fullest capacity. The degree, the manner in which you take unto yourself the assistance of that dependent affiliation, will determine your professional and personal success. Appraise, therefore, your membership and realize that without it you are but mediocre in your capacity to produce.

They who have ambitions, the desire to succeed, are not content with mediocrity. Your active county and state medical organization rôle places before you a ladder that will enable you to attain and hold a reputation for producing in full capacity.

* * *

DOCTOR, READ YOUR MAIL

The Council, some six months ago, sought to obtain the opinion and attitude of members upon two important pending questions. A questionnaire was sent out and with it was a postal card upon which questions were propounded for the member to answer. Replies were received from approximately 50 per cent of the members.

This month the mailman brought in two of these cards with mail date August 22—over six months after the questions had been submitted. Apparently these members, either just going or returning from vacations had "cleaned up" their mail and sent in their belated, now useless, answers. This leads to this comment—Doctor, Read Your Mail.

It is realized that most doctors' mail is loaded with many circulars, form letters, advertising material, and what not—much of which merits consignment to the waste basket. However, midst all such second- and third-class matter there is often some important mail—medical meeting announcements, notices of special clinical meetings, and postgraduate opportunities. Again, your mail will contain important announcements related to medical organizational work and a call for your advice and assistance. You, Doctor, are the personal loser if you miss these pieces in your mail.

It is recognized that you are busy, but that is no excuse for piling your mail unopened on your desk, window-sill, or in a drawer, to be sorted at some distant leisure moment. Such an attitude certainly will cause you to miss many an important statement and announcement.

No need of further comment. The closing suggestions are:

1. Doctor, read your mail *daily*.

2. If too busy, instruct your secretary, nurse, office girl, wife, son, or daughter to open your mail and call your attention to important items.

3. If someone else opens your mail, give implicit instruction that they are to place before you each day any and all announcements and communications, be it first- or second-class mail, from your county and state medical organizations.

Some important communications are going to be sent to you this fall. They will require your prompt attention. Therefore, Doctor, read your mail, or cause it to be read for you.

AMERICAN MEDICAL ASSOCIATION FELLOW AND MEMBER

There continues to be confusion as to the difference in these two classifications in our national organization.

Member.—By virtue of membership in a county and state medical organization the individual automatically becomes a member of the American Medical Association. This membership carries with it no privileges. A member cannot register or participate in any of the activities of the American Medical Association annual meeting.

Fellowship.—To become a Fellow the individual must be a member of his county and state organization. He must make *application* for fellowship. He pays annual dues of $7, for which he receives a weekly copy of the *Journal of the American Medical Association.* He is entitled to register at the annual meeting and participate in its activities.

Confusion: Many members subscribe and pay $7 a year for the *Journal of the American Medical Association.* For that reason he believes he is a Fellow. *He is not* because he has not filed an application for fellowship. He may become a Fellow by applying and have all the rights, including the official journal, for the same price he is now paying for his journal subscription. However, an application has to be made.

The new directory of the American Medical Association has just been issued. Fellows are indicated by a cross within a circle. Consult one of these directories in your local library or hospital. If you are a Fellow you will find this encircled cross following your name. If you are not recorded as being a Fellow, it is suggested that you write to the secretary of the American Medical Association for a fellowship application blank and make formal application.

If two or more Fellows occupy joint offices, one or more of them may, by the asking, receive one of the American Medical Association special journals in place of the official journal. By this arrangement, in place of receiving two or more weekly official journals the office will receive one official weekly journal and, in addition, one or more of the special journals, depending upon the number of Fellows sharing a common office.

Every member should be a Fellow of the American Medical Association. Are you?

* * *

HAVE YOU A PAPER?

County societies are resuming their meetings following a summer recess. We are often appealed to by program committees or county secretaries to suggest a speaker for their county meetings. In order that these appeals may be promptly answered, a register of available guest speakers, with their subjects, is being prepared.

Members who are willing to accept invitations to appear on the programs of neighboring county societies are invited to send in their names and titles of their papers to the State Secretary. May we have this coöperation?

* * *

NARCOTIC REGULATIONS

Through ignorance of the law, or inadvertently, reputable physicians may become violators. It is, therefore, desirable to direct attention from time to time to certain provisions in narcotic laws that must be observed at all times.

The outright sale of narcotics to addicts or the issuance of fraudulent or fictitious prescriptions constitute criminal acts.

Physicians licensed to issue narcotic prescriptions or to administer these drugs must keep a record for two years, giving name and address of the person, the date, the character and the quantity of the drug, the purpose for which it was given. Such record shall be open to enforcement inspectors.

Ambulatory treatment of narcotic addiction is prohibited.

All prescriptions must be written in their entirety by the physician. Prescriptions written by your secretary, nurse, or druggist, and then signed by the physician is a violation.

The telephoning of a narcotic prescription is banned by the act.

Do not prescribe a hypodermic syringe or needle without a definite pathology.

Physicians are urged to write to the Division of Narcotic Enforcement, State Building, San Francisco, for a copy of the state law in order that you may guard against failure to properly comply with the law. Federal regulations may be secured from the Internal Revenue Bureau, San Francisco.

Demands of practice are prone to make one forgetful or careless. Hence the foregoing reminder. Enforcement officers are charged with a duty. They have no discretion but to enforce the law. Physicians have no discretion but to observe the law.

* * *

WHY BECOME A MEMBER?

Our Association is very desirous of having every eligible physician in California affiliated as a member through the local county medical society. Officers of these constituent units have time-consuming official duties that frequently prevent them from contacting eligible nonmembers. There are eligible nonmembers willing to join, but they wait till they are invited to do so. There are others who would join if they were enlightened as to the benefits of membership and what this organization is doing in their behalf.

To extend an invitation and to point out the benefits of membership is the duty and obligation of every member who knows or contacts a nonmember. Your officers and Council request that you assume and discharge this obligation. To assist you in doing so, a few reasons are advanced for you to transmit to the nonmember to obtain his application.

Under present conditions, and under conditions that will probably arise, it is impossible for a physician to do himself justice unless he is an active member and takes an active part in organized movements.

The public is learning to look askance upon the physician who is not a member of his county medical society. They conclude that there must be something wrong with him. Nonmembers do not gain or hold community confidence.

Educational Benefits.—County, district, and state meetings, with scientific discussions and clinical presentations; regional postgraduate clinics; postgraduate courses at medical colleges; medical libraries; monthly copy of California and Western Medicine.

Legislation.—Representation in legislative councils and chambers that opposes untoward legislation and sponsors desirable legislation related to public health welfare. Opposition to pernicious initiatives that seek to impose impossible conditions upon physcians and seeks to obtain political and lay domination of medical practice and care.

Public Education.—Through lectures, institutes, press releases, and through contact and advisory services, sound public opinion is inspired in regard to all questions concerned with public and private health.

Committee Activities.—Through standing and special committees and the Council, public, professional, and personal interests are conserved and professional qualifications and standing are advanced.

Membership Dues.—State dues, $15 per year plus county dues that vary from $3 to $20 per year, except in Los Angeles and San Francisco counties. Note: Social club's dues range from $60 to $200 per year for the privilege of playing golf, bridge, athletics, and buying food and drinks. These benefits are not comparable to the personal benefits derived from medical organization membership.

These are but seven features and are a few reasons as to why an eligible physician should become a member. Members can enlarge upon industrial recognition, insurance companies' preferences, lower malpractice insurance rates, hospital staff appointments, and national benefits.

It is hoped that these comments will induce every member to determine to obtain membership applications from among his medical associates. Do so now and turn them in to your county secretary.

"SKEET SHOOTERS," ATTENTION!

The golf tournament, feature of annual meeting entertainment programs, will find a counter-attraction at our 1937 Del Monte session. "Skeet" members have come to the fore and are developing plans for a skeet shoot. Dr. Alfred L. Phillips has been designated as chairman and organizer.

Members interested are requested to write to Doctor Phillips, Farmers and Merchants Bank Building, Santa Cruz, and give him the information requested in the following letter:

July 21, 1936.

Dear Doctor Warnshuis:

In talking with members of the California Medical Association from all over the State, I find that there are many who enjoy trap or skeet shooting. It occurs to me that an organization of these members along similar lines as our golf organization might make an added attraction at our annual meetings.

In order to determine how much enthusiasm there is for this sport, I would suggest that notice of such a proposal be published in CALIFORNIA AND WESTERN MEDICINE with a questionnaire to be filled out by those interested. If the response warrants, a tournament can be arranged for the next annual meeting at Del Monte, at which time a more permanent organization could be started.

The necessary information could be obtained from answers to the following questions:

What gauge gun do you shoot?

Do you prefer skeet ( ) or trap ( ) shooting?

I would anticipate with much interest the response to this proposal.

(Signed) ALFRED L. PHILLIPS.

* * *

ENDOWMENT RESERVES

Colorado medical men have perfected and incorporated a subsidiary group for the purpose of receiving, holding and investing financial funds and using the income earnings for organizational purposes. This subsidiary organization is about the same and is possessed of like powers as the Trustees Of The California Medical Association. Colorado has, however, initiated an active campaign for contributions, and reports receipt of certain amounts of gifts and bequests. We congratulate the Colorado profession on its foresightedness and its success in completing their organization. Other states may well do likewise. As far as we know and have learned, Colorado, Califonia, and Michigan are the only states that have provided for the receiving, holding, and operation of an endowment reserve that will hold its principal intact in perpetuity.

In recent issues it has been suggested to our members that they give earnest consideration to contributing to our principal fund and to transmit their subscriptions to the state office. Up to the present no such bequests or contributions have been received. This further comment is being made for the purpose of stimulating endowments. Members have had time for consideration and determining what amount they can and will contribute. May we now have an expression of their conclusions? One hundred $500 contributions equals $50,000. One hundred $1,000 subscriptions equals $100,000. One hundred $2,000 subscriptions amounts to $200,000. Ten $5,000 bequests means $50,000, and five $10,000 bequests creates a like amount. The total would be $450,000. This sum would yield annually between $18,000 and $20,000 for enlarged organizational work and accomplishments. Members and the public would reap and profit thereby. May this Association obtain that response is fervently hoped for by all who are concerned with our future. Will *you* remit the amount you are able to contribute?

* * *

ENDORSEMENTS OF LEGISLATIVE PROPOSALS

To County Secretaries:

Candidates for the 1937 Legislature possibly will begin to draft bills which they propose to introduce in the legislature. Officers and members of county medical societies will be approached for expressions of opinion, comment, or endorsement of such legislative proposals.

Our Council and Legislative Committee urgently advises and requests that county societies and individual members *consistently* refrain from expressing opinions and thereby placing themselves on record, possibly to subsequent embarrassment and disadvantage.

All proposed legislation related to public health and medical sevices is carefully studied and reviewed by our Legislative and Public Policy Committee. Following such study, recommendations are made to our county societies and members.

In all legislative, health and medical matters, be guided by the recommendations of our Legislative Committees, which will be transmitted from our Association headquarters. In plain words: Do not endorse or comment upon any proposed legislation related to public health, medical care or services until you have obtained full information from Association headquarters and have ascertained its recommendations. Individual members are urged to conform to this advice and request.

By direction of Council's Executive Committee.

F. C. WARNSHUIS, *Secretary*.

Do You Know?

That autopsies were performed on the three assassinated Presidents of the United States?

Nonmembers pay higher premium rates for malpractice insurance protection than do members of county medical societies?

Consultation with irregular practitioners has been declared unethical by the Judicial Council of the American Medical Association.

X-ray films are the property of the radiologist.

If you endorse the driver's license of a minor you are liable for the damage that that driver occasions while driving an automobile.

That for twenty-five cents you can obtain a package containing recent articles on a given medical subject from the Packet Library, American Medical Association, 535 North Dearborn Street, Chicago. Just write in, stating subject, and packet will be sent to you, to be returned in one week.

A Line of Type

1. The practice of medicine is a journey, not a destination.
2. Favorite prescriptions tend toward careless prescribing.
3. Your Association membership certificate rates framing and display in your office.
4. Journal advertisers are your patrons deserving your patronage.
5. Constructive suggestions are welcomed by county and state officers.
6. Publicity hounds have little claim for recognition of their professional ability.
7. Develop a hobby in order to enjoy a fuller life.
8. Take time to tell the nonmember why he should apply for membership.
9. Cynicism, subtly employed, is often mistaken for argument.
10. Self-complacency receives a jolt from a look within.

The load of tomorrow added to that of yesterday, carried today, makes the strongest falter. Shut off the future as tightly as the past. No dreams, no visions, no delicious fantasies, no castles in the air, with which, as the old song so truly says, "Hearts are broken, heads are turned." To youth, we are told, belongs the future, but the wretched tomorrow that so plagues some of us has no certainty, except through today. Who can tell what a day may bring forth. Though its uncertainty is a proverb, a man may carry its secret in the hollow of his hand. Make a pilgrimage to Hades with Ulysses, draw the magic circle, perform the rites, and then ask Tiresias the question. I have had the answer from his own lips. The future is today—there is no tomorrow! The day of a man's salvation is *now*—the life of the present, of today, lived earnestly, intently, without a forward-looking thought, is the only insurance for the future.—Sir William Osler.

C. M. A. DEPARTMENT OF PUBLIC RELATIONS†

Political Activity

The recent nominating conventions of our nation's two leading parties and the approaching national, state, and local elections in November should, we trust, cause every citizen to give some time and thought to party platforms, qualification of candidates, and matters which concern public health welfare and professional interests. Organized medicine does not seek to discourage partisanship on the part of its physician members. Organized medicine does not lend itself to political or candidate partiality. As an organization we do not unite as a unit with any particular party or party candidates. Let that be clearly understood.

In the political campaigns of this fall, matters which concern public health and physicians may become issues. It is upon these issues that organized medicine has an obligation and a right to become not only vocal, but politically active. Having ascertained a candidate's opinion and attitude upon these questions, organized medicine is justified in endorsing or opposing a candidate or candidates.

When as a unit we do endorse or oppose a candidate, the public, the party, and the candidate should be distinctly informed that the position assumed is not to be construed as carrying with it organized medicine's endorsement or opposition to any party or its platform. The position that is assumed is based solely upon a candidate's position in regard to public health or medical measures, and in the interest of public welfare. It is a non-partisan attitude.

Whatever benefits the medical profession also benefits the public. Politicians seemingly do not understand that in this as in all of our other public activities our main concern is public welfare. That in questions concerning public health and medical care, organized medicine is the only and most competent group capable of determining what is best for all citizens.

We cannot expect the public to accept what we advise as being right because we say so. Our reasons must be stated fully and clearly so that all may understand and be guided accordingly.

We have a right to ask candidates to declare themselves upon questions in which we have an interest. We have a duty to enlighten candidates as to the right attitude that should be assumed in regard to the questions of the campaign in which we have a vital interest. We repeat, it is our right and obligation to support or oppose a candidate when our judgment indicates the position we assume. In exercising that right and in discharging that obligation we are non-partisan.

* * *

Legislation—What of the Future?

The constitutional amendments and initiatives that will appear on the November ballot Number 24. Not a single one of them has any reference to the practice of medicine, public health, medical care or medical service. It is, therefore, not deemed advisable to print the entire twenty-four proposed initiatives, as they will be sent to each voter in the voters' handbook.

It will be noted that the proposal to admit part- and full-pay patients to county hospitals, the dog-pound regulation (antivivisection), and "cult" and health legislation all failed to qualify or seek a place on the ballot. Voters will not be called upon to pass on these questions.

This is very gratifying. We are disposed to believe that our public health education program is beginning to be productive and that an informed public perceives the pernicious objects of these proposals. The Hall of Medical Science at the San Diego Exposition, visited by over a million persons, press releases, lay talks, press items on scientific medicine, the functioning of the Public Health League, the educational activities of county societies, members taking time to inform their patients and friends as to medical practices and principles—all these and other measures undoubtedly are molding and directing sound public opinion in regard to public and private health. We repeat, an informed public will not be misled by the specious arguments of proponents for unsound practices. Educational measures are recording results.

The time has not come, will never come, when our Association and its county units can restrict an aggressive program of public health education. Our efforts must go on and on unceasingly. Our responsibility and obligation are fixed and permanently so. Public minds and opinions must be kept abreast of medical progress. The stormy days encountered in the past decade were mainly due to the fact that in our zeal to take unto ourselves the discoveries made by our science, we left the public far behind because we neglected to keep it abreast and informed as to our progress. Such a state of affairs cannot be permitted to reoccur.

In place of relaxing our efforts we are impelled to extend and increase them. That is our purpose. To that end, and for the purpose of enhancing present results, county societies and state and county committees are requested to direct a program that embraces:

(*a*) Series of public health meetings, sponsored by lay groups and addressed by speakers from our Speakers' Bureau.

(*b*) Local public health institutes.

(*c*) Furnishing legislators with dependable public health welfare information in order to obtain sound legislation.

(*d*) Extend individual understanding as to proved medical practices and the manner in which it does conserve welfare.

(*e*) Expose the unsound claims of uneducated individuals who seek to profit by means of their bizarre representations.

By these means we shall hasten the day when California will be rid of charlatanism and pseudo-disciples in the field of health welfare and medical care. To that end do we direct our efforts. For that purpose every member is called upon to participate in this feature of organizational activity.

* * *

Forestry Medical Corps

UNITED STATES DEPARTMENT OF AGRICULTURE
FOREST SERVICE
CALIFORNIA REGION

San Francisco, July 1, 1936.

California Medical Association,
Four Fifty Sutter Street,
San Francisco, California.

Dear Doctor Warnshuis:

Your letter of June 27, addressed to Mr. Show, is received.

I wish to express my appreciation to you and your associates for your splendid efforts in connection with the organization of the Forestry Medical Service of the California Medical Association.

It goes without saying that your organization should prove exceedingly invaluable in time of need and, while I trust that it will not be necessary to call upon your membership often, yet it is gratifying to know that you are ready if occasion demands.

A copy of this letter is being sent to Mr. Charles G. Dunwoody of the California State Chamber of Commerce for his information.

Very truly yours,
S. B. SHOW, *Regional Forester.*

760 Market Street.

---

† The complete roster of the Committee on Public Relations is printed on page 2 of the front advertising section of each issue. Dr. Charles A. Dukes of Oakland is the chairman, and Dr. F. C. Warnshuis is the secretary. Component county societies and California Medical Association members are invited to present their problems to the committee. All communications should be sent to the director of the department, Dr. F. C. Warnshuis, Room 2004, Four Fifty Sutter Street, San Francisco.

Forestry Medical Service

Long ago Californians organized voluntary fire departments to answer the alarm at any hour, day or night. Long ago, too, they formed Vigilante Committees to poise the scales of justice when injustice cried out. Today, again Californians have seen a need and set up a voluntary organization to meet it. Ultimately, its possibilities know no end—in time or in space.

If your child gets burned you call the doctor. If the occupants of your car are injured you call the Health Department. If a major catastrophe (like an earthquake or a flood) strikes whole cities, what do cities do? If they do not have well-organized "Major Disaster Councils," they are apt to turn helplessly to a thousand-and-one arms of mercy that do their work as best they can in a welter of confusion. People die or suffer needlessly.

The Forestry Medical Service of the California Medical Association is an army of 485 knights of mercy, scattered over the state, mobilizable in an hour after the call goes out, ready to give their skill, their time, and their transportation costs, in aiding burned or injured fire-fighters in California forests. This is their prime object, but they—and the balance of the six thousand membership of the California Medical Association who are virtually reserves in the Forestry Medical Service—are ready at a signal to meet any public emergency.

The whole thing stems from an oldish idea cherished by Director Charles G. Dunwoody of the Conservation Department of the California State Chamber of Commerce, which has long aided and abetted the organization and manipulation of fire-fighting crews throughout the fire-hazard sections of the state. Last year, the problem was presented to the California Medical Association which, like the real service body it is, took it up wholeheartedly.

Almost immediately applications for membership in the voluntary medical corps began to pour in. Only doctors of highest professional standing and qualities of endurance were accepted. Last summer, their first in action, thousands of burned and injured fire-fighters were treated (at no cost to themselves or Government agencies) by these men who left their homes, brought their own instruments, paid their own transportation, and often underwent great discomfort, or even danger, to reach the suffering. During the great Malibu fire in Southern California, for example, 2,200 cases were treated.

The doctors are aided by a smaller group of lay helpers (also volunteers from the district) who act as stretcher-bearers and liaison officers, and by Red Cross nurses and ambulance units.

The whole is coördinated, like so much clockwork, from the twentieth floor of the Four Fifty Sutter Building, San Francisco, where the California Medical Association has its headquarters. Dr. Frederick C. Warnshuis, Association Secretary, is chief medical officer of the Service. Under him are six regional medical officers, under them are thirty-six county medical officers, and under them are the 485 Service members. If a call comes from a federal or state forest officer, the chief medical officer sends out some of his men. If the fire is a bad one he may need them all. If it is a very bad one he may need to contact the regional medical officer, who will send reinforcements from another county. In the event of a major catastrophe, medical and first aid would stream in from the whole state, if need be.

And because these doctors are not just fire-time heroes, they give winter instruction in first aid and first-aid equipment.

"To our knowledge," says Doctor Warnshuis, "the Forestry Medical Service of the California Medical Association is the first and only thing of the kind in any country or time. Other western states are planning to follow the lead."—From *Sunset Magazine.*

There is an idea abroad among moral people that they should make their neighbors good. One person I have to make good: myself. But my duty to my neighbor is much more nearly expressed by saying that I have to make him happy if I may.—Robert Louis Stevenson.

COMPONENT COUNTY MEDICAL SOCIETIES

VENTURA COUNTY

The May meeting of the Ventura County Medical Society was held at the Ventura County Country Club on Tuesday, the 9th.

Following dinner, Doctor Achenbach presented Dr. Mark Glaser of Los Angeles, who gave a paper on the *Differentiation of Psychoneurosis and Malingering.* He then showed two reels of films, illustrating these two types of cases.

Doctor Shore entertained us with pictures of his recent hunt for mountain lions.

Business Meeting.—It was voted as follows:

That the delegate be instructed to support the plan for hospital insurance which was approved by the Council of the California Medical Association at Coronado.

That the Society present $25 to the Public Health League of California.

One of the members was contacted by Mrs. Young, who is attempting to start a nurses' registry and physicians' exchange, and asked him to have the Society lend its official weight to the plan. Since it is a private enterprise, to be operated for profit, the members felt the Society should have no connection with the enterprise.

Doctor Coffey announced that Mr. Ben H. Read, speaker for the next meeting, would like to have the dentists present also. The following committee was appointed to invite the dentists: Doctors Rey of Oxnard, Drace of Ojai, Osborn of Fillmore, Gronhovd of Santa Paula, and Hendricks of Ventura.

* * *

The June meeting of the Ventura County Medical Society was held at the Ventura County Country Club, Saticoy, on Tuesday, the 9th.

This was a joint meeting of the dentists and physicians of Ventura County. There were thirty-four present. More interest was shown, in regard to legislative matters, than at any previous meeting.

Following dinner, Mr. Ben H. Read addressed the group upon the subject of *Legislation.*

The following members were appointed to the Legislative Committee by President Shore: Doctors Coffey of Ventura, Rey of Oxnard, Strong of Santa Paula, Osborn of Fillmore, and Drace of Ojai.

As the hour was late, the meeting was adjourned without holding the usual business meeting.

A. A. Morrison, *Secretary.*

CHANGES IN MEMBERSHIP

New Members (32)

Alameda County.—Harry Abrons, Dudley P. Bell, James F. Brady, Malcolm B. Hadden, Morton S. Havemann, Kenneth B. Jenkins, Joseph H. Milliken, Daniel F. Sullivan.

Los Angeles County.—Harvey E. Billig, Jr., Sidney B. Brownsberger, Behle B. Burns, J. Harold Cantarow, George H. Douglass, G. R. Dunlevy, Basia Gingold, Arthur F. Hall, Jr., Frederick Kellogg, Barney M. Kully, Max A. Levine, Herbert V. Mellinger, Lyle A. Mourer, Dwight T. Randall, Clinton A. Roath, Jr., Julius R. Scholtz, Sidney G. Sonneland, Kenneth D. Wright.

Monterey County.—Rudolph O. Griess.

Placer County.—Daniel Louis Hirsch, Harold L. Karo.

Sacramento County.—Edgar C. Haag, Harry O. Lovell.

San Diego County.—James W. Callaway.

Transferred (3)

J. F. Neilson, from San Luis Obispo County to Ventura County.

C. C. Vardon, from Los Angeles County to Alameda County.

Clinton A. Wilson, from Santa Barbara County to Los Angeles County.

In Memoriam

Buskirk, William Henry. Died at Los Angeles, August 7, 1936, age 56. Graduate of the University of Michigan Medical School, Ann Arbor, 1904. Licensed in California in 1920. Doctor Buskirk was a member of the Los Angeles County Medical Association, the California Medical Association, and a Fellow of the American Medical Association.

+

Chase, Raymond E. Died at Glendale, July 14, 1936, age 58. Graduate of the University of Southern California School of Medicine, Los Angeles, 1901, and licensed in California the same year. Doctor Chase was a member of the Los Angeles County Medical Association, the California Medical Association, and a Fellow of the American Medical Association.

+

Dougherty, Edwin Everett. Died at Los Angeles, July 17, 1936, age 60. Graduate of the Indiana University School of Medicine, Bloomington, 1910. Licensed in California in 1914. Doctor Dougherty was a member of the Los Angeles County Medical Association, the California Medical Association, and a Fellow of the American Medical Association.

+

Hicks, John Robert. Died at Tulare, August 1, 1936, age 65. Graduate of the Central College of Physicians and Surgeons, Indianapolis, 1897. Licensed in California in 1914. Doctor Hicks was a member of the Tulare County Medical Society, the California Medical Association, and the American Medical Association.

THE WOMEN'S AUXILIARY TO THE CALIFORNIA MEDICAL ASSOCIATION[†]

MRS. ANDREW J. THORNTON..............................President
MRS. ROBERT M. FURLONG..
....Editor and Chairman of Publicity

County Auxiliary Reports

Los Angeles County.—The final meeting of the Auxiliary year was held in the Association building on June 2, at which time our loyalty was somewhat divided in that we regretfully ushered out of office our past president, Mrs. John V. Barrow, and her group of directors, who have served for more than two years, while at the same time we eagerly welcomed our charming new president, Mrs. Clifford A. Wright, and her board, who will direct our affairs for the ensuing year. In Mrs. Barrow's farewell address, in which she outlined the various activities of the past year, she stressed the fact that while there had been progress, we had, in fact, only arrived upon the threshold of a great future and that the big opportunity lay before us. That the Auxiliary has felt it a great privilege to work under the inspired leadership of our president was evidenced by the applause at the conclusion of Mrs. Barrow's remarks, the whole assemblage standing in acknowledgment of their appreciation. Upon being installed as the newly elected president, Mrs. Wright presented her board: Mrs. Simon Jesberg, first vice-president; Mrs. E. M. Pallette, second vice-president; Mrs. Eric E. Larson, recording secretary; Mrs. J. F. Friesen, treasurer; Mesdames J. Martin Askey, W. H. Leake, Mark A. Glaser, F. B. Settle, A. T. Newcomb, and John P. Nuttall, directors. Mrs. James F. Percy, who attended the American Medical Association convention in Kansas City, gave a very newsy report of the women's activities there, announcing that Mrs. Philip Schuyler Doane had been honored by election to office as third vice-president of the National Woman's Auxiliary.

As a very lovely climax to our last program of the year, Mrs. Alfred Swan, artist and resident of China for fifteen years, made an old Chinese saying, "Carry a picture in your heart," a reality for each one as she portrayed the beauties of China, using her own paintings to illustrate her talk. Gowned in an exquisite Mandarin coat and surrounded by old Chinese embroideries, Mrs. Swan transported us into the land of crumbling architecture, yet enduring in spirit, because the Chinese believe only culture is worthy of preservation, and this they have done. "There are as many different stories told about China," said Mrs. Swan, "as there are people who have returned from there, and that is because they have different eyes; but I shall show you China through the eyes of a painter." She started her pictorial journey from Peking, unlike any other Chinese city, since it was built by Ghengis Kahn, a Mongol, who revered space, and therefore planned a city of wide thoroughfares and of spacious courtyards. The curved roof, so characteristic of Chinese architecture, derives its origin from the outline of the tent, the early home of these nomadic tribes, and this heritage led them to blend and harmonize their architecture rather than to dominate and to conquer nature, as is our habit. From North China we traveled southward, with Mrs. Swan's beautiful pictures guiding our way. We were left with an admiration for the Oriental, whose philosophy would inspire the lowliest peasant to place a tablet over the doorway of his mud hut, bearing the inscription, "The home of ten thousand joys."

A membership breakfast was held in the beautiful gardens of Mrs. William A. Swim, attended by 150 members and guests. At this time fifty new names were added to our list, thus making our county membership the largest in the United States.

Mrs. Harold E. Crowe, *Corresponding Secretary.*

* * *

Honoring Mrs. John Vincent Barrow and her retiring executive board, Mrs. Clifford Andrews Wright, newly elected president of the Woman's Auxiliary to the Los Angeles County Medical Association, will entertain at a garden tea today. Among honor guests will be Mesdames William A. Swim, Walter H. Boyd, Arthur J. Annis, H. E. Schiffbauer, W. O. Leach, Philip Stephens, C. D. Hubbard, Ray Miller, Franklin Farman, Mark A. Glaser, and Harold Crowe.

Hostesses assisting Mrs. Wright who are members of the new executive board are: Mesdames Simon Jesberg, Edward M. Pallette, Eric A. Larson, J. F. Friesen, John P. Nuttall, J. Martin Askey, W. H. Leake, F. B. Settle, A. T. Newcomb, and Robert L. Carroll.

Others are: Mesdames James F. Percy, Philip Schuyler Doane, Frank E. Detling, Samuel D. Ingham, W. H. Olds, Joseph Robinson, Lillian Bellah, A. Brockway, Peter McArthur, Irving R. Bancroft, and Ross Moore.—*Los Angeles Times,* June 30, 1936.

It is only rarely that a child is better than his home influence. He may be smarter than his parents or more successful or more beautiful, but his moral strength and his habits of life and his intellectual leanings will largely be those that he inherited and that he acquired or developed in his home. Since we cannot make the world over in a day, there is our point of beginning.

Begin to think of your child as the descendant of a thousand generations that have made on it an indelible mark of tendencies, instincts, passions, ambitions, habits and abilities or disabilities. This link in the long chain of your heredity is in the forge and on the anvil of home environment. It can be molded, shaped, strengthened, or it can be left weak and full of flaws. Are you going to make a stronger link in the long chain or a weaker one?—From "The Harvest of the Years," by Luther Burbank and Wilbur Hall.

[†] As county auxiliaries of the Woman's Auxiliary to the California Medical Association are formed, the names of their officers should be forwarded to Mrs. Robert M. Furlong, chairman of the Publicity and Publications Committee, Linden Lane, San Rafael. Brief reports of county auxiliary meetings will be welcomed by Mrs. Furlong and must be sent to her before publication takes place in this column. For lists of state and county officers, see advertising page 6. The Council of the California Medical Association has instructed the editor to allocate two pages in every issue for Woman's Auxiliary notes.

MISCELLANY

Under this department are ordinarily grouped: News Items; Letters; Special Articles; Twenty-five Years Ago column; California Board of Medical Examiners; and other columns as occasion may warrant. Items for the News column must be furnished by the fifteenth of the preceding month. For Book Reviews, see index on the front cover, under Miscellany.

NEWS

Coming Meetings

American Medical Association, Atlantic City, New Jersey, June 7-11, 1937. Olin West, M. D., 535 North Dearborn Street, Chicago, secretary.

California Medical Association, Del Monte, May 2-5, 1937. F. C. Warnshuis, M. D., 450 Sutter Street, San Francisco, secretary.

Nevado State Medical Association, Reno, September 25-26, 1936. Horace J. Brown, M. D., 20 North Virginia Street, Reno, secretary.

Rocky Mountain Tuberculosis Conference, Albuquerque, New Mexico, September 28-29, 1936. Arnold Minnig, M. D., 638 Metropolitan Building, Denver, Colorado, secretary.

Medical Broadcasts*

The American Medical Association broadcasts have been discountinued for the summer months. A new series is under consideration for the autumn and winter of 1936-1937.

San Francisco County Medical Society. — The radio broadcast program for the San Francisco County Medical Society for the month of September is as follows:

Tuesday, September 1—KYA, 6 p. m.
Tuesday, September 8—KYA, 6 p. m.
Tuesday, September 15—KYA, 6 p. m.
Tuesday, September 22—KYA, 6 p. m.
Tuesday, September 29—KYA, 6 p. m.

* * *

Los Angeles County Medical Association.—The radio broadcast program for the Los Angeles County Medical Association for the month of September is as follows:

Tuesday, September 1—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, September 5—KFI, 9 a. m. Subject: The Road of Health.
Saturday, September 5—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, September 8—KECA, 10:30 a. m. Subject: The Road to Health.
Saturday, September 12—KFI, 9 a. m. Subject: The Road of Health.
Saturday, September 12—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, September 15—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, September 19—KFI, 9 a. m. Subject: The Road of Health.
Saturday, September 19—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, September 22—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, September 26—KFI, 9 a. m. Subject: The Road of Health.
Saturday, September 26—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, September 29—KECA, 10:30 a. m. Subject: The Road of Health.

Recent Exhibits in the Crummer Medical History Room of the University of California Medical School. These exhibits have included a display of material relating to the development of modern dental practices and anesthesia. This was arranged for the meeting of the American Dental Association held in San Francisco the early part of July.

During the Sylvatic Plague Conference held at the University of California Medical School in June, there was a special exhibit of material relating to plague in California. In this exhibit, in addition to scientific publications, there were pamphlets and news items relating to the controversy as to whether plague actually existed.

Physicians at University of California Summer School for Research. — Three distinguished physicians have joined the pharmacy laboratories of the University of California Medical School for research work throughout the summer.

Dr. S. A. Peoples, fellow in the Maudsley Hospital of London, and noted psychiatrist, is making a study of depressants on the central nervous system, as is Dr. P. K. Knoefel, former National Research Council Fellow at the Medical School.

Dr. George Emerson, head of the department of pharmacy in the University of West Virginia, is engaging in laboratory work on the problems of anesthetic shock.

Doctor Peoples has just been appointed assistant professor of pharmacy in the University of Louisville, and will take up his duties there in the fall.

Salesmanship Is Vital to Public Health. — A physician or surgeon should go to school all of his active life in order to keep adequately informed on the latest procedures, and the University of California Medical School will do what it can within its resources to bring this about.

This is the first declaration of policy of Dr. Williams McKim Marriott, who has just taken over his duties as dean of the school, succeeding Dr. Langley Porter, retired.

Not only should the doctors be kept fully informed professionally, but "the Medical School has a job of salesmanship on its hands to fully acquaint the public with what it is doing," Doctor Marriott said.

"It is the province of the Medical School to provide advanced education, in so far as possible, through organized postgraduate work. Naturally, we would like to see the time when doctors will not have to go East or to Europe for further study. We would like to give them the same advantages right here at home. While I was in the Medical School of Washington University, St. Louis, I had many students from California, and I presume that this is true in other eastern centers. It would be a fine thing if we could keep them here instead."

Regarding public health salesmanship, any such program must be dictated by extreme caution and conservatism, "which should make it all the more effective," he said. The school should be civic-minded as well as health-minded, with fullest coöperation being extended to such organizations as chambers of commerce and service clubs, in driving home the message of good health and well-being.

While in St. Louis, Doctor Marriott was a member of the board of directors of the Convention and Publicity Bureau of the St. Louis Chamber of Commerce. He has taken a temporary home in San Francisco with Mrs. Marriott and their 12-year-old son, McKim Marriott.

---

* County societies giving medical broadcasts are requested to send information as soon as arranged (stating station, day, date and hour, and subject) to CALIFORNIA AND WESTERN MEDICINE, 450 Sutter Street, San Francisco, for inclusion in this column.

Rocky Mountain Tuberculosis Conference.—This year's session will be held at the Franciscan Hotel, Albuquerque, New Mexico, on September 28 and 29, 1936. Listed among the speakers are the following Californians, with their subjects:

When Should Artificial Pneumothorax Treatment Be Discontinued? by Munford Smith and Howard W. Bosworth of Barlow Sanatorium, Los Angeles.

Anesthesia to the Tuberculous, by Arthur E. Guedel, Professor of Anesthesiology, University of Southern California.

Tuberculosis in the Aged, by John W. Shuman, Associate Professor of Medicine, College of Medical Evangelists, Los Angeles.

Does Tuberculin Deserve a Place in the Therapy of Tuberculosis?—Thirty Years in Retrospect, by Harry C. Warren, California Sanatorium for the Treatment of Tuberculosis, Belmont.

For further information, address the secretary-treasurer, Arnold Minnig, M.D., 638 Metropolitan Building, Denver, Colorado.

New Payment Plans Outlined.—In an effort to help both the doctor and the patient, several new plans of payment have recently been announced by the Berkeley General Hospital. In order to avoid confusion in the minds of the profession, they are outlined below:

1. *Cash Payment in Advance.*—Traditional plan of collecting one week in advance.

2. *Patient's Installment Plan.*—The admission of responsible private patients with a small down payment and small weekly or monthly installment payments.

3. *Collection of Physicians' Fees.*—The extension of the installment plan to add doctor's professional fees to the patient's installment contract in any case where the doctor might feel that the hospital, because of the security behind its written agreement and its follow-up system, is in a better position to collect from the patient than he is. This medical credit service is entirely optional with the physician and is not taken up with the patient unless so requested by the physician.

4. *Part-Pay Medical and Dental Clinics.*—This plan is not open to private patients, but provides only for the care of deserving patients who, upon strict social service investigation, and with the consent of the last attending physician, have been found eligible for out-patient care or hospitalization by the clinic staff at reduced part-pay rates in small installment payments.

Interstate Postgraduate Association of North America.—The twenty-first International Assembly of the Interstate Postgraduate Medical Association of North America, under the presidency of Dr. David Riesman of Philadelphia, Pennsylvania, will be held in the public auditorium of St. Paul, Minnesota, October 12, 13, 14, 15, and 16, with preassembly clinics on Saturday, October 10, and postassembly clinics Saturday, October 17, in the hospitals of St. Paul.

The aim of the Program Committee, with Dr. George Crile as chairman, is to provide for the medical profession of North America an intensive postgraduate course covering the various branches of medical science. The program has been carefully arranged to meet the demands of the general practitioner, as well as the specialist. Extreme care has been given in the selection of the contributors and the subjects of their contributions.

In coöperation with the Minnesota State Medical Association, the Ramsey County Medical Society will be host to the Assembly and has arranged an excellent list of committees, who will function throughout the Assembly.

An invitation is extended to all members of the profession who are in good standing in their state or provincial societies to be present and enjoy the hospitality of the medical profession of St. Paul. A registration fee of $5 will admit each member of the medical profession in good standing to all the scientific and clinical sessions.

A list of the distinguished teachers and clinicians who will take part on the program will be sent on application to the managing director.

Special railroad rates will be in effect.

For further information write Dr. W. B. Peck, managing director, Freeport, Illinois.

County Hospital Head Retires.—Norman R. Martin, executive superintendent of the Los Angeles County General Hospital, retired from that post today.

Martin, who had served the county for two long periods since 1915, recently submitted his resignation to the Board of Supervisors because of ill health.

He joined the county service in 1915, when he was named superintendent of charities. At that time he supervised all relief work and had charge of the county hospital and the county farm.

In 1917 he was named executive superintendent of the county hospital, in addition to his duties as superintendent of the charity department. He held the two offices until 1923, when he retired to enter private business.

In 1931 he returned to county service again as executive superintendent of the new hospital, and supervised the occupancy of the new unit.

He won national prestige for his administrative work in the big institution. And today, as he retired, he received hundreds of tributes from fellow workers at the institution and many private citizens.—*Los Angeles Evening Herald and Express,* August 15, 1936.

Pacific Association of Railway Surgeons.—The thirty-fourth annual meeting was held at Reno, Nevada, September 4 and 5. Headquarters were at the Riverside. The program included the following papers:

Address of the president, Dr. D. H. Moulton.

Industrial Aspects of Lead, Arsenic, and Mercury; Carbon Tetrachlorid, Benzine, etc., Dr. Verne R. Mason of Los Angeles.

The Traumatic Faker, William Raines, Esq., of Los Angeles.

Fracture Symposium: The Newer Methods of Treatment.

Historical Notes on the Development of Orthopedic Surgery (illustrated), Dr. L. D. Prince of San Francisco.

The Important Rôle of the (1) Eye and (2) Ear Specialist in Industry, (1) Dr. R. A. Woodhull, Los Angeles; (2) Dr. H. B. Graham, San Francisco.

The Radical Repair of Hernias, with Fascial Sutures (Motion Picture), Dr. H. G. Holder of San Diego.

Chlorid Depletion: Its Surgical Significance, Doctors Curtis E. Smith and Alson R. Kilgore of San Francisco.

The Hazards of Hypertension, Dr. Philip King Brown of San Francisco.

Coffey-Humber Malignancy Research, Doctors W. B. Coffey, F. D. Humber; H. H. Beard, Professor of Biochemistry, Louisiana State University.

Late Lues in Railway Employees, Dr. John M. Graves of San Francisco.

Mussel Poison Ban Extended to Southern Counties. Like Mata Hari, the famous woman spy of war-time Paris, the phosphorescent sea glow-worm of the southern coast of California is beautiful but dangerous, for it is one cause of the much-feared shellfish poisoning.

For several years the State Board of Health has enforced a rigid quarantine on sea mussels from Monterey County north to the Oregon line during the summer months. This year, however, owing to the death of two Los Angeles residents who ate mussels gathered from a Ventura County beach, the ban has been extended south of Monterey Bay for the first time.

The Ventura outbreak marked the first time that toxic mussels had been discovered south of Monterey. Now investigations are being conducted as far south as the Mexican border to prevent new attacks of this deadly poison.

The source of shellfish poisoning was unknown for many years, during which it was claiming lives every season. Then the Hooper Foundation of the University of California, after exhaustive research, found that the mussels were made poisonous by the presence in the water of microscopic animal organisms, or protozoa, swept to the surface of the ocean by off-shore currents. Further study revealed that the glow-worms, which produce beautiful marine displays off the Southern California coast, are also a source of the paralytic poison which may cause death within two hours after eating infected shellfish.

American Board of Obstetrics and Gynecology.—The next written examination and review of case histories of Group B applicants by the American Board of Obstetrics and Gynecology will be held in various cities in the United States and Canada on Saturday, November 7, 1936.

Application blanks and booklets of information may be obtained from Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh (6), Pennsylvania. Applications for this examination must be filed in the secretary's office sixty days prior to the scheduled date of examination.

A Newspaper Item of Interest to All Physicians and Surgeons Licensed in California.—The following article appeared in *Clinical Osteopathy*, Vol. 32, No. 1, p. 21, July, 1936. *Clinical Osteopathy* is published monthly by the California Osteopathic Association at 799 Kensington Road, Los Angeles. The excerpt follows:

CALIFORNIA DRUGLESS LICENTIATES MAY QUALIFY FOR PHYSICIANS AND SURGEONS

"At a meeting held June 29 to July 1 in Los Angeles, the California Board of Osteopathic Examiners adopted a resolution which opens the way for a number of drugless licentiates heretofore barred from obtaining a physician and surgeon certificate to obtain such certificate with a minimum of sacrifice of time from practice.

"Drugless licentiates who have completed the necessary premedical courses as prescribed by the State Medical Practice Act, and who comply with Section 10 of this Act, may now take a minimum of one trimester at the College of Osteopathic Physicians and Surgeons to qualify for the examination in additional subjects necessary to become eligible for a physician and surgeon certificate. These subjects are: biochemistry; advanced bacteriology and pathology; surgery; materia medica, pharmacology and therapeutics; general medicine, including clinical microscopy; advanced obstetrics and gynecology.

"This will be welcome news to drugless licentiates who have desired to obtain the physician and surgeon certificate, but have been unable to do so because of the unduly large sacrifice of time heretofore necessary to become qualified.

Public Health Administration in Sacramento.—Dr. Herbert F. True, City Health Officer of Sacramento, has issued the report of the Sacramento City Health Department for the year ending December 31, 1935. This report presents a careful and interesting account of the activities of an efficient municipal department of public health.

At a per capita cost of 78 cents, reduced to a net cost of 30 cents through revenues from fees, the people of Sacramento are provided with adequate safeguards to the health of the community. During 1935 no epidemics of food poisoning occurred in Sacramento, although many outbreaks occurred in various communities scattered throughout the state. Tuberculosis did not increase greatly in prevalence and, as a result of better housing and economic conditions, there was a marked lowering in the number of pneumonia cases. Rabies was kept under control, and Doctor True refers to the fact that the police dog is seen less frequently. Records show that the slashing, cutting injuries from this particular animal are of frequent occurrence. The infant mortality rate rose slightly and a limited outbreak of smallpox occurred. Diphtheria gained a considerable start in one school district, the health officer recording with regret 138 cases with four deaths. Doctor True believes that all of these cases and deaths were avoidable and makes the following comment: "Many parents who will give a child life insurance policy protection, and even fire protection against the loss of a home, neglect this health protection so vital to the little one." Scarlet fever and measles showed increases in prevalence, as was common throughout most of the cities and states.

The Sacramento City Department of Health is organized into twelve divisions—Administration, Public Health Nursing, Child Hygiene, Clinics, Dental Clinic, Emergency Hospital, Laboratories, Sanitation, Food and Market Inspection, Plumbing Inspection, Animal Welfare and Pound, and the Division of Cemeteries. It will be recognized that several of these activities are not ordinarily assigned to a department of public health, although some of the work done by each of such divisions may have a certain public health significance.

The department was entered for the fourth time in the United States Inter-Chamber Health Conservation Contest, advancing to sixth place from twentieth place in 1931, when the original entry was made.

In making a plea for private physicians to take part in the preventive portion of public health work, Doctor True makes the following quotation from an address by Dr. Howard Morrow, President of the California State Board of Public Health:

"Today many children die in the morning of life, and men and women die prematurely from diseases that are controllable or preventable by methods already available.

"These methods are not alone sanitation nor other impersonal procedures such as quarantine, food protection measures, etc., but include that most important need of a close coöperation between patient and physician.

"The full-time public health officer is in a most favorable position to lead in calling the attention of the public to the value of this close physician-patient relationship and to urge its establishment and continuance."

LETTERS

Concerning contribution of California Medical Association to Lane Library.

July 23, 1936.

Dr. Frederick C. Warnshuis
California Medical Association
450 Sutter Street
San Francisco, California

My dear Doctor Warnshuis:

Doctor Chandler sent me the check from the California Medical Association and I wish to thank you again for all your kindness to us. We appreciate the generous donation of the Association and are very grateful for the help they are giving us.

Very sincerely,
Louise Ophüls,
Librarian, Lane Medical Library.

Concerning California Medical Association contribution to Barlow Medical Library.

Los Angeles, July 22, 1936.

Frederick C. Warnshuis, M.D.
Secretary, California Medical Association
Four Fifty Sutter Street
San Francisco, California

My dear Doctor Warnshuis:

I take great pleasure, in behalf of the Barlow Medical Library, of accepting the check of the California Medical Association representing the per membership contribution to the Library.

Very sincerely,
E. Vincent Askey, *Secretary.*

Concerning placement of the Department of Professional and Vocational Standards of the State of California on the mailing list of California and Western Medicine.

Sacramento, August 6, 1936.

Dear Doctors: Answering your letter of July 23, 1936, advising me that you had placed my name upon the complimentary mailing list to receive your publication, I wish to express my thanks for your thoughtfulness. Being charged with a certain degree of supervision over the activities of medical groups, I am naturally interested in up-to-date editorial and Association news, and regard the action of the California Medical Association as furnishing me another source of information which will be both interesting and valuable.

Again thanking you, I am

Very truly yours,

William G. Bonelli, *Director.*

Concerning Federal (United States Public Health) regulations on psittacosis (interstate shipment of psittacine birds from California).*

Copy

United States Public Health Service

USPHS No. 0425—General (Psittacosis).
X 1950—California Bird Breeders' Association.

July 30, 1936.

Mr. Gilbert C. Lee, President Emeritus
Southern California Bird Breeders' Association
Room 200, 110 Center
Los Angeles, California.

Sir:—This office is in receipt of your letter of July 24, requesting, on behalf of the California Bird Breeders' Association, that Section 15½, Interstate Quarantine Regulations, governing the interstate transportation of psittacine birds, be rescinded.

With respect to your statement that no state other than California has complied with the law in regard to the laboratory examination of birds, your attention is invited to language of Section 15½ of the Interstate Quarantine Regulations relating to the certification of interstate shipments, which requires that inspections of bird-breeding establishments shall be supplemented by "such laboratory examinations of birds . . . as may be deemed necessary to enable the certifying authority to determine that the birds offered for shipment are free from psittacosis infection." While the Public Health Service has received no specific information which would indicate that the health authorities of states other than California are not making laboratory examinations of birds in connection with the certification of interstate shipments, it may be pointed out that the regulations do not *require* such examination in every instance, but leave to the discretion of the state health authority determination as to whether laboratory examination of birds may be necessary. It has been expected that each state health officer would be guided in this respect, to a considerable extent, but the history of the establishment in relation to the presence or absence of psittacosis infection in the past. In this connection it may be stated that within the past few years the only outbreaks of human psittacosis traceable to parrakeets shipped in interstate commerce were directly attributable to infected stock originating in California. There has been no evidence to indicate that the infection is present in any other state.

The Interstate Quarantine Regulations place upon the bird-breeding establishments and the transportation companies the responsibility of seeing that the requirement with respect to the age of birds that may be shipped in interstate commerce be observed. If you will furnish this office with the names and addresses of bird breeders and the names of the transportation companies who have violated the regulations by shipping or accepting for shipment birds under the age limit specified, I shall be very glad to initiate at once an investigation of this matter and to refer to the Department of Justice any violations of the regulations which can be proven.

I note your statement that Section 15½ of the Interstate Quarantine Regulations works great hardship upon bird breeders by virtue of the fact that the California Department of Public Health has taken 20 per cent of the birds of each breeder for laboratory examination. As this office has repeatedly pointed out to your Association, the promulgation of Section 15½ of the Interstate Quarantine Regulations, with the rigid requirements and activities of the California Department of Public Health directed toward cleaning up psittacosis in California, probably saved the bird-breeding industry in your state. At the time the latest amendment to the regulations was promulgated and the State Department of Public Health adopted its present procedure in connection with certification, a number of states were demanding that the Public Health Service set up an embargo against *all* interstate shipments of psittacine birds, and were considering the establishment of individual state embargoes against such shipments. It is my belief that if the bird breeders of California are wise they not only will refrain from complaining of the restrictions which have been placed upon the breeding and shipping of parrakeets and other psittacine birds, but accept the activity of the State Department of Public Health as being one of the most helpful things that could be done for the industry, and give their fullest coöperation in meeting the requirements which, after all, have been set up for the protection of the industry as well as the public. The Public Health Service has full confidence in the activities of the State Department of Public Health directed toward keeping infected birds out of interstate traffic. That the effort toward this end has been effective is indicated by the fact that no outbreak of human psittacosis has been reported outside of California since the State Department of Public Health adopted its new procedure. It is believed that the recent history of psittacosis in California and in other states where fatal outbreaks of the disease were directly traceable to infected birds from California fully warrant the procedure adopted by the State Department of Public Health in connection with the certification of interstate shipments.

While it is regrettable that psittacosis infection in aviaries in California has made it necessary to impose certain restrictions on interstate shipments for the protection of the public, and it is realized that the application of these restrictions has worked a hardship upon the bird breeders, one must not lose sight of the public's right to be protected from the hazard of illness and possible loss of life. I do not consider it advisable to recommend the rescinding of Section 15½ of the Interstate Quarantine Regulations at this time.

Very truly yours,

(Signed) Thomas Parran,
Surgeon-General.

cc: to Dr. W. M. Dickie,
Director, California State Board of Health.

Concerning "abortion racket."

Board of Medical Examiners
State of California

San Francisco, August 3, 1936.

To the Editor:—Referring to the clipping from the Los Angeles *Times* of July 27, 1936, commenting on what we term the Pacific Coast abortion racket, wherein is related that "Los Angeles politicians *has* guaranteed 'arrest protection' to the operators of illegal surgery clinics. . . . It is reported that at a price of several thousand dollars a month they had arranged to 'fix' not only police and officers of the State Medical Board, but members of the District Attorney's office as well."

This article strikes us as a smoke screen in an endeavor to discredit the Board of Medical Examiners.

---

The so-called abortion racket of Pacific Coast magnitude has been under investigation by the Board of Medical Examiners, through its executive officer, for the past two years. We have communicated the facts to the District Attorneys' offices of the counties of Alameda, Los Angeles, and San Francisco.

The promoters became rather firmly entrenched. Offices have been maintained in Seattle, Portland, San Francisco, Oakland, San Jose, Los Angeles, Hollywood, and San Diego. The denouement came early in June this year in the form of a San Francisco grand jury indictment of some thirty-one individuals, said to be connected with this ring, whose names were printed in California and Western Medicine (News Items), July, 1936, page 112. Then followed a raid made by Assistant District Attorney McMahon of San Francisco County, accompanied by police officers of the San Francisco Homicide Squad, when office records, equipment, etc., were seized in San Francisco and Oakland. They then journeyed to Los Angeles, where, accompanied by a representative of the District Attorney's office, offices were raided, and within the past two weeks offices in San Diego have been raided.

Practically all of the indicted individuals have been arraigned in the San Francisco courts, and we understand the trial is set in the Superior Court of San Francisco for early in October.

Under date of July 13, 1936, the Los Angeles District Attorney advised that he had been informed the local police department intended within a week or two to submit evidence to the Los Angeles County grand jury.

It is a matter of common rumor that the asserted promoter of this ring has openly boasted of his "protection." Before the curtain finally falls we anticipate that his boasts will be proven false.

The latest rumor is that endeavors will be made by the defense to have continuances granted from time to time in hopes that when the trial is finally held important witnesses will have "disappeared."

In so far as the Board of Medical Examiners is concerned, rest assured that no "protection" can be obtained at any price by those engaged in violation of law. Our board, individually and collectively, has always endeavored to perpetuate those high ideals which have marked the ethical practice of medicine in America, as well as to enforce the provisions of the Medical Practice Act. True, we have occasionally found that the Board has been "sold out" by some unscrupulous employee, but as soon as the discovery is made, no time has been wasted in ousting such employee.

The interest of the Board of Medical Examiners will continue in the active prosecution of the so-called Pacific Coast abortion ring until its final determination in the courts. We have had most commendable support from District Attorney Matthew Brady and his assistant, Mr. McMahon, of San Francisco, which promises to result in the complete eradication of this organized racket.

Very truly yours,
C. B. Pinkham, M.D.,
Secretary-Treasurer.

* * *

SURGERY RING TO BE PROBED

Charges that a syndicate of Los Angeles politicians has guaranteed "arrest protection" to the operators of illegal surgery clinics are to be investigated next week by the county grand jury.

Plans for the jury inquiry were disclosed by police and District Attorney's aids when it was learned that a group of surgeons, asserted members of a state-wide illegal operation "ring," had undertaken to renew activities in Los Angeles after having been driven out of business several months ago.

Reopening offices in a downtown building, which they had hurriedly evacuated upon the threat of police raids, the surgeons boasted to prospective patients, it was reported, that, at a price of several thousand dollars a month, they had arranged to "fix" not only police and officials of the State Medical Board, but members of the District Attorney's office as well. — *Los Angeles Times*, July 27, 1936.

SPECIAL ARTICLES

THE AMERICAN BOARD OF INTERNAL MEDICINE, INC.

The American Board of Internal Medicine, Incorporated, February 28, 1936, completed its organization on June 15, 1936. The officers chosen were: Walter L. Bierring of Des Moines, chairman; Jonathan C. Meakins of Montreal, vice-chairman; and O. H. Perry Pepper of Philadelphia, secretary-treasurer. These officers, with the following six members, constitute the present membership of the Board: David P. Barr of St. Louis, Reginald Fitz of Boston, Ernest E. Irons of Chicago, William S. Middleton of Madison, John H. Musser of New Orleans, and G. Gill Richards of Salt Lake City.

The term of office of each member will be three years, and no member can serve more than two consecutive three-year terms.

The organization of the Board is the result of effective effort on the part of the American College of Physicians in conjunction with the Section on Practice of Medicine of the American Medical Association, and these two organizations are represented in the membership of the Board on a five to four ratio, respectively.

The American Board of Internal Medicine had previously received the official approval of the two bodies fostering its organization, as well as that of the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

The purpose of the Board will be the certification of specialists in the field of internal medicine, and the establishment of qualifications with the required examination procedure for such certification.

While the Board is at present chiefly concerned with the qualification and procedure for certification in the general field of internal medicine, it is intended to inaugurate immediately after July 1, 1937, similar qualification and procedure for additional certification in certain of the more restricted and specialized branches of internal medicine, as gastro-enterology, cardiology, metabolic diseases, tuberculosis, allergic diseases, etc. Such special certification will be considered only for candidates who have passed at least the written examination required for certification in general internal medicine. The operation of such a plan will require the active participation and coöperation of recognized representatives from each of such special fields of medicine.

Each applicant for admission to the examination in internal medicine will be required to meet the following standards:

General Qualifications

1. Satisfactory moral and ethical standing in the profession.

2. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies will not be required.

Professional Standing

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.

2. Completion of an internship of not less than one year in a hospital approved by the same council.

3. In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

Special Training

1. Five years must elapse after completion of a year's internship in a hospital approved for interne training before the candidate is eligible for examination.

2. Three years of this period must be devoted to special training in internal medicine. This requirement should include a period of at least several months of graduate work under proper supervision in anatomy, physiology, biochemistry, pathology, bacteriology, or pharmacology, particularly as related to the practice of internal medicine.

This work may be carried on in any domestic or foreign medical school or laboratory recognized by the Council on Medical Education and Hospitals of the American Medical Association as offering appropriate facilities for this type of postgraduate experience; or it may include a period of at least several months of graduate work under proper supervision in internal medicine or in its restricted and specialized branches in any domestic or foreign hospital, clinic, or dispensary, recognized by the above Council as offering appropriate facilities for this type of postgraduate experience.

3. A period of not less than two years of special practice in the field of internal medicine or in its more restricted and specialized branches.

The American Board of Internal Medicine does not propose to establish fixed rules for the preliminary training of candidates for certification in this field. Broad general principles for training, however, may be outlined, although such suggestions as are made must, of necessity, be subject to constant changes reflecting the dynamic nature of the specialty.

A sound knowledge of physiology, biochemistry, pharmacology, anatomy, bacteriology, and pathology, in so far as they apply to disease, is regarded as essential for continued progress of the individual who practices internal medicine. The mere factual knowledge of medicine and its basic sciences is not sufficient. The candidate must have had training in their use in furthering his understanding of clinical medicine. This implies practical experience under the guidance of older men who bring to their clinical problems ripe knowledge and critical judgment. Preparation to meet this requirement adequately may be even more difficult to obtain than the so-called scientific training. It may, however, be acquired in the following ways:

(*a*) By work in a well-organized hospital outdoor clinic conducted by competent physicians.

(*b*) By a prolonged period of resident hospital appointments likewise directed by skilled physicians.

(*c*) By a period of training in intimate association with a well-trained and critical physician who takes the trouble to teach and guide his assistant rather than to require him only to carry out the minor drudgery of a busy practice.

4. The Board does not consider it to the best interests of internal medicine in this country that rigid rules as to where or how the training outlined above is to be obtained. Medical teaching and knowledge are international. The opportunities of all prospective candidates are not the same. Some may have the opportunity of widening their knowledge by a period of study abroad. Others, at the other extreme, may be restricted to a comparatively narrow geographic area and their detailed training must be obtained in short periods scattered over a long time. Although it is laid down that at least five years must elapse between the termination of the first interne year and the time when the candidate is eligible to take the examination, a longer period is advisable. The Board wishes to emphasize that the time and training are but means to the end of acquiring a broadness and depth of knowledge of internal medicine which the candidate must demonstrate to the Board in order to justify it in certifying that he is competent to practice internal medicine as a specialty. The responsibility of acquiring the knowledge as best he may rests with the candidate, while the responsibility of maintaining the standard of knowledge required for certification devolves on the Board.

Method of Examination

The examination required of candidates for certification as specialists in internal medicine will comprise: Part I (written) and Part II (practical or clinical).

Part I: The written examination is to be held simultaneously in different sections of the United States and Canada, and will include: (*a*) Questions in applied physiology, physiological chemistry, pathology, pharmacology, and the cultural aspects of medicine. (*b*) Questions in general internal medicine.

The first written examination will be held in December, 1936, and candidates successful in this written test will be eligible for the first practical or clinical examination which will be conducted by members of the Board near the time for the annual session of the American College of Physicians at St. Louis in April, 1937. The second practical examination will be held at Philadelphia near the time of the annual session of the American Medical Association in Atlantic City in June, 1937.

The fee for examination is $40, which must accompany the application, and an additional fee of $10 is required when the certificate is issued.

Application blanks and further information can be obtained by addressing the office of the chairman, Walter L. Bierring, M.D., 406 Sixth Avenue, Des Moines, Iowa.

CALIFORNIA STATE DEPARTMENT OF PUBLIC HEALTH

Report to Governor's Council

A monthly report of the California State Board of Health presents a survey of the major activities of the department during the preceding thirty days. Members of the California Medical Association who wish to orient themselves concerning the nature and scope of the State Health Department's work can do so by perusing the July 27, 1936, report submitted to Governor Frank F. Merriam's Council by Dr. W. M. Dickie, Director of Public Health. The present members of the California State Board of Public Health are: President Howard Morrow of San Francisco, Vice-President Edward M. Pallette of Los Angeles, George H. Kress of Los Angeles, William R. P. Clark of San Francisco, Gifford L. Sobey of Paso Robles, Gustave Wilson of Sacramento, and Walter M. Dickie of Sacramento, executive officer. The report follows:

BUREAU OF ADMINISTRATION

Activities of the Director.—The director spent the entire month of June in the northern part of the State. Conferences were held in San Francisco relative to prosecutions under the Pure Drugs Act; the development of nursing courses in training schools; the enforcement of wine standards; the regulation of the packing of dog foods; the development of a crippled-child program under Social Security; the development of full-time county health units; regulations pertaining to the packing of fish and fish products; organization of courses in the Western School of Public Health; the enforcement of regulations for the control of custard fillings in bakery goods; the enforcement of standards for jams and jellies; a proposed research study into dysenteries and diarrheas in California; and many other subjects including those pertaining to interdepartmental matters.

Among those officials from outside of the State who conferred with the director during the month of June were the following. . . . (Names deleted to conserve space.)

BUREAU OF EPIDEMIOLOGY

Food Poisoning.—At this season of the year, outbreaks of food poisoning occur commonly. Most of these outbreaks are of bacterial origin and are due to exposure to contamination and to holding at temperatures favorable to the growth of bacteria. Several such outbreaks were investigated during the month of June. One of them involved eclairs purchased from a bakery, laboratory examinations of which revealed a heavy contamination with staphylococci, the ordinary pus germ. Nineteen cases were involved in this outbreak, and the proprietor of the bakery involved was given instructions in the prevention of similar contaminations of this food product. Another outbreak involved a students' camp which housed 190 persons. No particular food product, however, was incriminated. It is important at this season of the year that all food products, particularly those containing cream-custard fillings, should be manufactured under the cleanest of conditions, and unless they are eaten immediately after their manufacture they should be stored at low temperatures.

Septic Sore Throat.—An outbreak of septic sore throat, scarlet fever, and diphtheria in an orphans' home was investigated. There were twenty-one cases of septic sore throat, six cases of scarlet fever, with four suspects, two cases of diphtheria, and six carriers. Milk was produced from the home herd, under filthy conditions, and one of the milkers had suffered from sore throat before the epidemic started. Instructions for the production of a better milk supply were given.

Typhoid Fever.—Outbreaks of typhoid fever were investigated in three different sections of the State. Two of them involved drinking water. One of these found its source in raw river water containing sewage, and the other came from a well located close to a dilapidated privy. The third outbreak involved an infected milk supply.

Typhus Fever.—A father and son living near the Mexican boundary developed chills and fever followed by an eruption, the cases developing into typical typhus fever. It is possible that the disease was transmitted by rat fleas. Typhus fever is endemic in Mexico, where it has prevailed over a long period of years. It runs a long and uncomfortable course. Fortunately, it is not of frequent occurrence in California, but isolated outbreaks occur occasionally.

Other Investigations. — Among other investigations undertaken during June were those involving infectious mononucleosis, leprosy, coccidioidal granuloma, suspected smallpox, tularemia, and plague.

General Health Conditions.—Measles, chickenpox, and German measles decreased in prevalence during June. The statistics for influenza indicate an increase. This is more apparent than real, however, as the figures represent cases that occurred earlier in the year, but which were not reported promptly. Epidemic poliomyelitis (infantile paralysis) continues at a normal level and shows no indication of increased prevalence at this time.

BUREAU OF FOOD AND DRUG INSPECTION

Imported Eggs.—Forty-six cases of imported egg products were inspected during June, and fees for the same were collected as provided in the law. A complaint charging the use of imported eggs without proper labeling was dismissed in a San Diego justice court upon recommendation of the District Attorney's office, because of the firms' willingness to comply with the law at all future times.

Egg Noodles.—Inspections were made of alleged egg noodles shipped into California from the Hawaiian Islands. Laboratory investigations disclosed that the product contained no eggs, but was artificially colored with coal-tar dye. The shipment of 3,500 pounds was quarantined.

Used Containers.—A survey of used containers, both glassware and cooperage, was continued during June. Special attenton was given to pickle manufacturers who use second-hand barrels. Coopers, in general, have indicated a willingness to coöperate in keeping containers unsuitable for food products from reaching the hands of the food packers. Second-hand bottle-washing places were inspected and warnings given with reference to the use of trade-marked bottles.

Drug Inspections. — Samples of hair tonics, laxatives, and a wide variety of so-called homeopathic remedies were inspected. Various so-called health institutions were investigated, and one was cited to appear to show why prosecutions should not follow for the advertising of certain remedies and treatment prohibited under the Statutes of 1919.

Wine Inspections.—Approximately seventy-five official samples of wines were submitted to the laboratory during June. Difficulties were encountered with owners of small wineries, as their cellars are not equipped to care for wine properly. Several actions against wineries are pending, many of whose products are mislabeled. Upon receipt of laboratory findings of substandard wine, the Attorney-General's office prepares the libel order, which is handled through the Superior Court, and at the same time an order is issued to show cause why the questionable material should not be destroyed or other disposition made.

Other Inspections.—Other inspections carried on during June covered canned goods, dog, food, lima beans, alimentary paste, "chicken turnovers," dried fruit, jams, and jellies.

Food Materials Destroyed. — During June more than 40,000 gallons of red wine and claret were destroyed because they were substandard and unfit for human consumption. Almost 1,000 sacks of onions were destroyed because of decay, and 177 cases of canned goods, damaged by fire, also met with destruction. Every effort was made to salvage these products for human consumption.

Prosecutions. — Eleven cases were prosecuted by this bureau during June. These involved violations of the Pure Food and Pure Drug Act. Fines ranging from $10 to $25 were imposed.

BUREAU OF CANNERY INSPECTION

Animal Food.—On June 3, definitions and standards for the commercial packing of dog food in California were established by the State Board of Public Health. Representative samples of each pack under the new regulations were submitted to the laboratory, together with a copy of the formula used by the canner. This procedure was followed so as to assist the packers in determining that each formula met the necessary specifications. A system of coding has been introduced for the purpose of marking all goods packed in California and shipped outside of the State. In general, the packers of animal foods are coöperating in placing the industry on a sound basis.

Asparagus.—Seasonal packing of asparagus was completed in June. The federal control instituted on the packing of this product did not interfere with the volume, and a full packing season to the end of June was enjoyed by the industry. As a whole, the asparagus of 1936 is of very good quality.

Miscellaneous Products.—Among other food products packed during June under the supervision of the Bureau of Cannery Inspection were the following: artichokes, peas, health foods, hominy, lima beans, mushrooms, olives, pork and beans, puree, tomato soup, specialties, vegetable salad, tuna, and mackerel.

BUREAU OF SANITARY INSPECTIONS

Rodent Survey.—The rodent survey carried on by this bureau was continued during June in sections of Sonoma, Santa Cruz, Monterey, San Luis Obispo, Modoc, and Lassen counties. A total of 3,130 rodents was collected and examined. Intensive rodent-control activities are under way in Modoc and Lassen counties under the supervision of county agricultural commissioners coöperating with the State Department of Apriculture and federal officials. Rodent-control activities were also carried on in sections of Contra Costa, Alameda, and San Mateo counties. Totals of 18,000 acres were inspected and 60,000 acres were reinspected. . . .

Ocean Beaches.—At the request of Oakland city officials, investigations of complaints relative to the pollution of ocean beaches, both north and south of San Francisco, were investigated. It was found that twelve beaches were more or less littered with garbage and refuse of all sorts. Identification of material picked up on the beaches indicated that most of the refuse came from the boats which dumped Oakland garbage at sea. It was arranged to have all waste matter removed at the expense of the city, and crews of men were transported to clean the beaches thoroughly. Investigations were started to determine why refuse from the Oakland garbage boats floated ashore at this time. Ordinarily this waste is dumped at considerable distance from the shore line and is carried out to sea by strong currents.

Highway Eating Places Inspected.—Food supply places and service stations along the Yuba Pass Highway in Nevada and Placer counties and United States Highway

No. 50 in El Dorado County were inspected, with the following results:

Food-supply places inspected	72
Number satisfactory	38
Number with minor defects	22
Number unsanitary	12
Service stations inspected	48
Number satisfactory	31
Number with minor defects	11
Number insanitary	6

BUREAU OF LABORATORIES

Bacteriological Laboratory.—Following is the diagnostic detail of examinations made in this laboratory during the month of June:

Slides, prepared and examined for the diagnosis of diphtheria, tuberculosis, gonorrhea, malaria, rabies culture identification	3,107
Plate cultures made, examined and selected colonies transplanted during examination for typhoid, paratyphoid, dysentery, food poisoning, plague, unknown determinations, etc.	729
Culture tubes inoculated (fluid and solid media) for testing sugar reactions and other cultural characteristics during identification of unknown cultures isolated in blood, stool and food examinations, and sent in by other laboratories	908
Animal inoculations for virulence tests, Kellogg tests, tuberculosis of kidneys, meningitis, standardizing vaccines, making immune serums, etc.	478
Precipitation tests, principally for syphilis	4,422
Complement-fixation tests, principally for syphilis, but also for identification of cultures and immune serums	3,558
Agglutination tests, each one involving the making of eight different serum dilutions, centrifuging and examining; required for Widal tests for typhoid, undulant fever, typhus, tularemia, and for identification of cultures, etc.	492
Total of procedures	13,694
Number of cases represented	4,624

Biologics.—The following biologics were made in the bacteriological laboratory and distributed during the month of June:

Vaccine issued by the Bacteriological Laboratory during the month of June, 1936:	Cubic Centimeters
Triple typhoid	1205
Typhoid	600
Agglutinating antigens:	
Typhoid	355
Paratyphoid alpha	250
Paratyphoid beta	275
Brucella abortus	69
Tularense	57
Antigen for diagnosis of syphilis:	
Kolmer	100
Kahn	955
Kline	10
Tubes of culture media	204
Antisera:	
Typhoid	4
Paratyphoid alpha	1
Paratyphoid beta	1
Flexner dysentery	4
H R Y dysentery	2
Shiga dysentery	2
Sonne dysentery	3
Suipestifer	1
Aertrycke	1
Amboceptor	20

Ophthalmia neonatorum prophylactic outfits distributed during the month of June, 1936:	
Number of ampoules	5122

Chemical Laboratory.—During June two hundred official samples and thirty-one unofficial samples of foods and drugs were examined in this laboratory. These consisted mostly of wines, alimentary paste, flavoring extracts, and miscellaneous products. Out of the 231 samples examined, 136 were determined as illegal. In addition to these, fifteen samples were analyzed for state institutions, all but one of which were determined as legal.

Water and Sewage.—During June, 139 bacterial examinations and 148 chemical examinations of water were made in this laboratory. In addition, there were fourteen bacterial examinations of oysters and three bacterial examinations of clams.

BUREAU OF REGISTRATION OF NURSES

Activities of the Chief.—The biennial conventions of the American Nurses' Association, the National Organization for Public Health Nursing, and the National League of Nursing Education were attended in Los Angeles on June 21 to 27. It is estimated that 11,000 nurses from all parts of the United States were in attendance. Meetings were valuable from an administrative standpoint. The attendance of the chief and inspector of the bureau was profitable. During the month, studies of facilities for teaching medical nursing were made in one hospital. Classes were visited and commencement exercises attended at several schools of nursing. Preparation of examination questions and compilation of statistical material occupied a considerable portion of the month.

BUREAU OF SANITARY ENGINEERING

Sewage Disposal

New Projects.—Discussion of sewage disposal projects which have been dormant for quite a while have been revived at Placerville and at San Diego. Two of the state institutions, Sonoma State Home and Napa State Hospital, have projects which have been discussed with the Bureau with a view to inclusion in the next biennial budget. Bond issues or proceedings are in progress for sewer systems or changes in sewage disposal at Decoto, Carmel, Eureka, Shafter, and Ione. At Avenal, discussions are on over public ownership of an existing private sewer system and its extension to serve outlying areas. All these matters have been under discussion with the Bureau. Application was filed by the city of Stockton for additions to its sewage disposal facilities, and permit has been granted. The new sewage-treatment plant at Camarillo State Hospital was inspected, also the new plant at Santa Maria.

Complaints.—Sewage disposal at Napa and Napa State Hospital was investigated on account of complaints by fishermen against pollution of Napa Slough. The Bureau has made tests to measure the degree of pollution and has outlined a project for Napa State Hospital. Other complaints concern sewage disposal at St. Helena, pollution of Mokelumne River by winery wastes, and sewage disposal difficulties at Gorman. At the request of the County Health Officer, a question as to how far a home owner might be expected to sewer to connect with the public sewer system was looked into at Rodeo.

Community Sanitation.—With the close of this biennium there have been 9,844 privies constructed under this program. The project represents a contribution by home owners of $194,343.17, and 90,650 man days' labor contributed by WPA.

Special Mention.—Sewage disposal at Steckel Park near Santa Paula was reported on. Tests made at Belvedere Cove on account of the sewage menace to swimming.

Routine Inspections.—Routine inspections were made at Pacific Grove, Del Monte, Golden Gate Park, and Porterville.

Water

New Projects. — At the request of the Sonoma State Home, a new water treatment, involving a rearrangement of water supply, was blocked out for Sonoma Farm Colony. National City is building a new water-softening plant and has applied for a permit. It is noteworthy that this is the third large city to go in for water-softening in California within recent months, the others being San Mateo, where two kinds of water-softening plants are used, and Santa Barbara.

Filtration of the water supply of Kern County Park was discussed with the county surveyor. A filter plant at Summer Home Park to filter Russian River water was put into service this month. It is understood to be doing very good work on this river water.

Complaints.—Complaint was received from the city of Firebaugh against picnic grounds and a dance hall on a small piece of ground on the river bank above the Firebaugh intake. The complaint was referred to the County Health Officer. At Salinas the question was up as to getting an abandoned water well in a public street sealed up so as to prevent pollution of the underground water strata. A complaint against an open reservoir at San Carlos was referred to the sanitary inspectors. Another complaint was received against the poor grade of water in Grass Valley.

Special Mention.—Considerable time was spent on a new water supply for Locke, where recently a serious typhoid outbreak was traced to leakage of sewage into the water-supply well. An extensive survey into the condition of Monterey Bay as a source of water supply for the sardine canneries, was started by the Bureau this month. Tule River was surveyed on account of complaints of pollution by resorts. National Ice and Cold Storage Company bottled water, San Francisco, was inspected on request of the United States Public Health Service for use on common carriers. Further tests were made on Lake Elsinore in connection with the heavy algae infestation that has affected this lake for several months. A communication was addressed to the water department of San Francisco, with respect to covers on the city reservoirs.

Routine Inspections.—Routine inspections made at Santa Cruz, Napa State Hospital, and Sacramento filtration plant.

Mosquitoes.—Advice was given on mosquito control in Bakersfield and Marysville.

Shellfish. — After considerable effort, some men who were digging clams from highly polluted mud flats near San Quentin Prison were apprehended and the case dealt with through the Division of Fish and Game. Several sources of shellfish in San Francisco and Los Angeles were inspected for approval for use on interstate carriers, at the request of the United States Public Health Service. Difficulty with the safety of clams shipped from Oregon required considerable investigation and correspondence with the Oregon State Health Officer. Clams and other shellfish were checked up on in Marin County, Richmond, San Rafael, and San Francisco markets. The Bureau is endeavoring to get certain sewers in South San Francisco changed so as not to menace oyster beds in that locality.

Swimming Pools. — Swimming-pool filters were discussed for an orphange near Danville, also an unusual pool proposed in Contra Costa County. Plans for severing a cross-connection in the swimming pool at Beverly Hills were submitted and reviewed.

Miscellaneous.—A comprehensive paper by Abel Wolman, Chairman, National Water Resources Committee on Federal Activities in this field, was discussed by the Bureau at Los Angeles. Also two papers on sewage-disposal subjects were prepared for the University of Southern California Civic Training School. Several conferences were necessary in connection with the question over the status of public health engineers under the Engineers Registration Act. A conference was held with the Public Health Service over the future certification of waters used on common carriers. The Bureau is finding that this is becoming a very time-consuming chore. At the request of the City Health Officer of Berkeley, rinse waters in several laundries were studied for contamination and other characteristics, with a view to possible regulation. A report on sewage disposal in the central valleys was prepared for the Central Valleys Water Project. Considerable time was spent in preparing for instruction to be given by the Bureau at a sanitary school to be held at the University of California in July and August.

Laboratory.—Rendered opinion on 139 samples of water, fourteen samples of oysters, and two samples of clams.

BUREAU OF VITAL STATISTICS

More Births.—During the first four months of 1936 there were 26,250 births registered in California, as compared with 25,495 such events registered during the first four months of 1935. This represents a gain of 755 births.

More Marriages.—During the first five months of 1936 there were 20,604 marriages performed in California, as compared with 19,419 during a similar period of 1935. This represents a gain of 1,185 marriages.

Search of Records.—There were 1,567 searches of vital statistical records made by the Bureau during June and 620 certifications were sent out. The balance of the searches represent verifications and affidavits to amend records already on file.

BUREAU OF CHILD HYGIENE

Activities.—The Chief of the Bureau of Child Hygiene spent ten days out of the State attending the conference of Chiefs of Bureaus of Child Hygiene in Washington, D. C., under the auspices of the Federal Children's Bureau. At this conference material was presented for building new programs for maternal and child health. During the course of the conference the Chief spoke to its members on the California plan for health supervision of the children of migratory families. She discussed the supervision and administration of bedside nursing delivery service with the group at Maternity Center Association in New York, which has had this type of program in active service for some years. She also visited two full-time county health units in Kentucky to observe the interrelationship of child health with the full-time health unit there.

After returning, the Chief made field trips in order to organize the work for the new staff being added to the Bureau, and had many staff conferences with members, outlining and planning their work. On these field trips a two-day health conference was conducted at which eighty-five children were examined. A pediatrician joined the staff on June 2. She spent three days in the office during the course of the month, discussing with the Chief plans of work and arranging necessary materials. During the rest of the month she visited nine counties, inspecting six hospitals with maternity departments, four homes, and two county hospitals. In addition, she conducted fourteen child health conferences, examining 374 children, working with eleven nurses, and interviewing four health officers. A public health nurse joined the staff on June 15 and was assigned, temporarily, to the inspection of maternity homes and hospitals. She visited three counties during the course of which she made five investigations and inspected four licensed maternity homes and five licensed hospitals. During the month, distribution was made of 3,859 pieces of literature included in which were 373 sets of postnatal letters and 517 sets of prenatal letters.

BUREAU OF TUBERCULOSIS

Activities of the Chief.—During June the Chief of this bureau inspected the following tuberculosis hospitals: Olive View and Los Angeles General in Los Angeles County, Santa Barbara County Hospital, Monterey County Hospital, Santa Clara County Hospital, the San Francisco Hospital, the San Mateo County Hospital, and the Hassler Health Farm.

Meetings were held with the County Board of Supervisors of Monterey County and with the boards of supervisors of Tulare and Kings counties. Many conferences were held with health officers, county physicians, school executives, and other officials. A large part of the Chief's time was devoted to preparation for a survey of migratory labor in California, with special reference to tuberculosis problems among migrants. Statistical reports of tuberculosis morbidity and mortality in Monterey County were prepared. Preliminary reports of conditions pertaining to the health of migratory laborers in Riverside and Kern counties were received.

HEALTH OFFICERS OF THE STATE OF CALIFORNIA BY COUNTIES

June 15, 1936

Alameda County	Dr. I. O. Church, Oakland
Alameda	Dr. Peter Paul Baron
Albany	Dr. Jack L. Stein
Berkeley	Dr. Frank L. Kelly

TWENTY-FIVE YEARS AGO†

EXCERPTS FROM OUR STATE MEDICAL JOURNAL

Vol. IX, No. 9, September, 1911

From Some Editorial Notes:

Purely Personal.—The secretary of the Society and the editor of the *Journal* is tired, very tired. He has been ordered away to take a complete rest and to think as little as possible about the Society, its work, or its *Journal.* The Council has granted him a leave of absence for some months, and the Publication Committee has kindly undertaken to look after the publication of the *Journal,* under temporary editorship of Dr. D'Arcy Power. The work of building up and conducting the Society's affairs, while it has been at times hard and has involved a good deal of worry during the lean years, has also been most pleasant; to see something of real value grow from almost nothing has been a keen pleasure. Therefore, it is not without a distinct feeling of sadness that the secretary-editor obeys the instructions of his physician, closes his desk and leaves his office, to take the first real vacation in twenty years. To every member of the Society who has helped—and many have helped more than they know—the secretary-editor wishes to extend his thanks. . . .

(The above paragraph is from the pen of the late Philip Mills Jones, founder and editor of the official journal of the Medical Society of the State of California.)

From an article on "Clinical Observations on Migraine" by Herbert C. Moffit, M. D., San Francisco.

It is a pleasure in this gathering of specialists once again to acknowledge the great debt of the clinician to ophthalmology. No medical student of today should leave school and hospital without command of the methods of eye examination—the ophthalmoscope to the internist is as indispensable as the stethoscope. But during incursions into the borderland of your activity, the clinician not infrequently has chance to observe that the specialist, early in his career, builds too high a fence about his preserves and cuts off his view of the general broad field. A proper training in clinical medicine and neurology is essential to the interpretation by the ophthalmologist of many pupillary, muscle and fundus phenomena; the judicial habit of mind acquired at the bedside will curb tendencies toward narrow specialism and keep in check the enthusiastic advocate of eye strain as a source of all evil. . . .

From an article on "A Résumé of the Modern Operative Procedures in Ear Affections" by Dr. H. B. Graham, M. D., San Francisco.

It is not my purpose to give a complete description or discussion of the various operative procedures that are followed by the various otologists of today, but to review them cursorily in order to give my personal impressions concerning their value. . . .

From an article on "Some Types of Intestinal Indigestion Occurring in Young Children" by Langley Porter, M. D., San Francisco.

Any who have had experience in the examination of the stools of young children cannot fail to have been struck by the frequency with which free starch is found; nor can they have failed to notice that almost invariably the presence of this starch in the stools is accompanied by a very definite, although not uniform, series of clinical symptoms. . . .

---

† This column strives to mirror the work and aims of colleagues who bore the brunt of Association work some twenty-five years ago. It is hoped that such presentation will be of interest to both old and new members.

BOARD OF MEDICAL EXAMINERS OF THE STATE OF CALIFORNIA†

By Charles B. Pinkham, M.D.
Secretary-Treasurer

News

"Dr. Samuel A. Twain, Berkeley physician, today stood convicted on ten counts of failure to keep records of narcotic prescriptions. The doctor . . . was found guilty by a jury last night after forty-five minutes' deliberation. . . . Doctor Twain was arrested last December, and, in addition to charges of failing to keep records, was accused on two counts of illegal possession of narcotics. He was acquitted on this charge in May by a jury in Superior Judge Frank M. Ogden's court in Oakland." (Oakland *Tribune,* July 12, 1936.)

"Headquarters of an illegal operation ring, said by police to perform as many as twenty abortions daily, were raided at 327 Fillmore Street and 339 Waller Street. . . . Police Inspectors George Engler and Harry Husted said the Fillmore Street address, equipped with several beds and rest-room facilities, was the ring's appointment office. Interviews with a dozen women who visited there yesterday afternoon disclosed information which led the officers to the abortion 'hospital' at 339 Waller." (San Francisco *Examiner,* July 12, 1936.)

"At least one, and perhaps more, of the thirty-one defendants indicted in connection with the alleged operation of a state-wide illegal operation ring are prepared to turn State's evidence, it was indicated today. This was indicated when twenty-two of the defendants were arraigned before Superior Judge George J. Steiger on charges of conspiracy to commit illegal operatons and the commission of illegal operations. The court set October 13 as the trial date. . . . One defendant named in the indictment, Norman Powers, failed to appear in court. He is sought. William Byrne, one of the defendants, was arrested as he left the courtroom on a charge of wife abandonment on a complaint sworn to by William Heistuman, 3842 Fulton Street, his father-in-law." (Press dispatch dated San Francisco, July 10, 1936, published in the Oakland *Tribune,* July 10, 1936.)

"Twenty-three defendants in the coast-wide criminal operations ring faced Superior Judge George J. Steiger today to hear Assistant District Attorney John J. McMahon demand a swift trial 'because there are rumors of attempts to fix this case in San Francisco. . . . Reports have been circulating that R. L. Rankin, the central figure in this case, is trying to fix this case,' Mr. McMahon said. 'The story is that he " 'has a good *in* in San Francisco' " and will be able to stall this case. No such thing is going to happen. We want this trial to go on swiftly, and will oppose any continuances.' Rankin, one of the defendants, made no comment on Mr. McMahon's statement. Mr. McMahon also demanded that $2,500 bail of W. Norman Powers, another defendant, be forfeited when he failed to appear in court, despite the fact that Clarence Morris, defense attorney, produced a doctor's certificate stating Powers is ill in Seattle. 'I understand Powers is still carrying on his nefarious business in Seattle right now and that the medical certificate came from Rankin's own firm,' Mr. McMahon declared. Judge Steiger declined to forfeit the bail on Mr. Morris' promise that Powers would appear in court Monday." (San Francisco *News,* July 9, 1936.)

"The police homicide detail cracked down on three alleged abortion ring headquarters yesterday and arrested three men and five women. Acting on information from a woman informer, the police first closed in on a 'hospital'

WE'VE FAITH IN THE THINGS WE MAKE . . . . THAT EQUALS YOUR FAITH IN ALL OF THE THINGS YOU DO

MAYBE there's no other group in the world where perfect work is so constantly striven for . . . as in the hospital, medical field.

All that you do *is the best* that you can do and there's never a midway point that satisfies you.

It is the same with us.

We make BAXTER'S Intravenous Solutions in Vacoliters as fine as it is possible for us to make them. We've been doing that for years . . . more years, in fact, than any other manufacturer of solutions . . . doing nothing else, *to one end*, that BAXTER'S Intravenous Solutions in Vacoliters may be used by you with complete and utter confidence.

REDUCED RAILROAD RATES FROM ALL PARTS OF THE UNITED STATES AND CANADA

Law Pursues Feeble Germicides and "Health" Spray That Failed.—Disinfectants predominate in the list of prosecutions terminated during the past month under the Federal Insecticide Act, the Food and Drug Administration reports. Ineffective disinfectants are not only economic cheats but real health hazards, enforcing officials declare. Moth and ant preparations and agricultural insecticides are also included in the list. All defendants pleaded guilty.

James A. Haines, trading as the Haines Products Company, Carey, Ohio, was fined $50 and costs, total $70.50, for shipping in interstate commerce "H & D Health Spray," a product misbranded and adulterated under the provisions of the Insecticide Act. The "Health Spray" contained 94 per cent of water (a fact which was not mentioned on the label) and less of the active constituents than claimed. It was recommended as a disinfectant and germ destroyer for use by morticians, doctors, hospitals, homes, hotels, schools, state institutions, office buildings, beauty parlors, dry cleaners; steamship, cab, bus, and railroad companies.

It was further recommended for preventing the spread of colds, influenza, and other contagious diseases; to purify the air; to banish all odors, destroy moths, and drive out insects. The preparation was ineffective either as a germicide, disinfectant, or antiseptic; would not purify the air, banish odors, destroy moths, or drive out all insects, nor would it maintain or improve health, as the name would imply.

The American Pharmaceutical Company, a New Jersey corporation doing business in New York City, was fined $100 for shipping misbranded and adulterated "Solution Cresol Compound, U. S. P.," which failed to meet the requirements of the United States Pharmacopeia. The product was labeled so as to deceive and mislead the purchaser in that phenols other than U. S. P. Cresol, and fatty material other than linseed oil, were substituted for U. S. P. Cresol and linseed oil, and was further represented as containing only water as an inert ingredient, whereas it contained glycerin in addition to the water.

Three Misbranded Products.—A prosecution against Spratt's Patent, Ltd., Newark, New Jersey, resulting in a fine of $150, involved three misbranded products, "Spratt's Germicide," "Spratt's Antiseptic Germicidal Flea Soap," and "Spratt's Flea and Insect Powder," the last-named preparation being also adulterated. The Germicide contained inert substances, the labeling failing to bear the declaration of ingredients required by the Federal Insecticide Act.

The labeling also bore a number of false and misleading claims, among which were representations that the product was non-poisonous, would kill microbes of all kinds, would disinfect tainted land and kennels infected with mange, distemper or any contagious diseases. This preparation was also in violation of the Federal Food and Drugs Act because of false and fraudulent claims for gastritis, distemper, etc. The "Antiseptic Germicidal Flea Soap" was neither antiseptic nor germicidal, used as directed. It would not sterilize veterinary instuments, as claimed on the label, or be an effective treatment for ticks on dogs.

This product was also misbranded under the Federal Food and Drugs Act in that the label bore false and fraudulent claims of efficacy for use as a disinfectant and germicide for the treatment of wounds, ulcers, etc. The Flea and Insect Powder was both misbranded and adulterated, containing less than the amount of sulphur stated in the labeling.

As the result of an action brought in the Federal Court at Trenton, New Jersey, a fine of $575 was imposed on the Interstate Chemical Manufacturing Company of Jersey City, New Jersey, for shipping short-measure lime sulphur solution. The court suspended $500 of the fine, the remaining $75 to be paid in cash. The company was put on probation for six months with the stipulation that a report be made at the end of each month to the New York station of the Food and Drug Administration to the effect that an investigation had been made of formulas, labels,

Why Take a Chance?

You can be absolutely sure, doctor, when you recommend Heinz Strained Foods for babies and soft diet patients, that expected nutrient values are present. Chance—so large an element in home cooking—is eliminated. Fixed and uniform quality are assured at all times.

For one thing, Heinz Strained Foods bear the famous "57" Seal of Quality. This symbol of integrity has achieved its meaning through almost 70 years of constant endeavor to produce foods as fine, safe and wholesome as it is possible to make.

In addition, Heinz Strained Foods carry the approval of your own exacting profession. Each tin bears the Seal of Acceptance of the American Medical Association's important Council on Foods.

Depend on it, too, that baby will enjoy Heinz Strained Foods. They are as delicious as they are wholesome. Selective feeding tests have shown that infants actually seem to *prefer* these finer tasting foods.

So do not hesitate to recommend Heinz Strained Foods. You can do so confidently—with complete assurance that claims for their high quality and nutrient value are true in every respect.

NEW FREE BOOK of Heinz Nutritional Charts has just been published. You will find it helpful in prescribing to convalescents and soft diet patients as well as infants. Write for it care of H. J. Heinz Co., Dept. CW308, Pittsburgh, Pa.

and batch cards, to determine that the products manufactured were in compliance with law.

"Safe" Product Contains Poison.—The Bonide Chemical Company, Inc., Utica, New York, violated the Insecticide Act by shipping in interstate commerce its misbranded "Antzis," and a fine of $50 was imposed. This product was put up in tubes (similar to tooth paste tubes) fastened to a display card bearing the statement, "I am safe to use about the home." The quoted statement was made the basis of a misbranding charge, since the product contained thallium sulphate, which is a deadly and dangerous poison. Further misbranding was alleged in that the labeling bore extravagant claims which could not be substantiated, to the effect that the preparation would kill pests anywhere, would destroy ant colonies in from three to five hours, and would be effective against cutworms, sow bugs, slugs, etc.

Dainty pink, lavender, and light green hexagonal, perfumed naphthalene blocks with small wire molded in them for suspension purposes, wrapped in cellophane, formed the basis of a prosecution case against the Exo-Nox Company (Ralph Frederick Tipton, sole owner), Cincinnati, Ohio. The labeling bore the direction, "Exo Used for Moths. Unwrap and Hang Up." The product used as directed was worthless for the control of moths. A fine of $10 was imposed.

Henry A. Fischel, Inc., of Philadelphia, Pennsylvania, was prosecuted for failure to place the ingredient statement required by the Federal Insecticide Act on "Florantin." The preparation contained inert substances and was shipped, bought and used for insecticidal purposes. A fine of $10 was imposed.

Caustic Poison Act.—A case brought in the Federal Court for the Southern District of New York against Merck & Company, Rahway, New Jersey, and New York, New York, for violation of the Federal Caustic Poison Act resulted in a fine of $25. The action involved "Creolin Pearson," a product containing over 5 per cent of

(Continued on Page 41)

HOW CAMP INTRODUCES NEW MODELS

An important factor in the Camp Professional Support Service is the thoroughly trained Camp field staff, whose duty it is to make themselves available to physicians and surgeons—either in professional offices, clinics or at medical conventions . . . so that the profession may be informed as to Camp supports, the various series and the use of each series.

Before a man or woman is added to the Camp field staff, he or she has usually had some form of professional training or experience. Some are graduate nurses. Others have studied medicine. Several have been associated with manufacturers who market other types of products to physicians. All, however, regardless of their previous experience, receive at the Camp factory a thorough course of training in the purpose of supports in general, and the design and construction of Camp supports and their application in particular. Before members of the field staff are granted territories, they work with experienced travellers for a period of a year, after which they are closely supervised.

As new considerations for better supports are presented—and this is being done continually—and finally amalgamated into the manufacture of a new series of supports typed to body build, it is necessary of course to inform those who sell Camp supports of these new developments. Frequent broadcasts from the Camp medical advisory board and the Camp designing staff are therefore sent to the Camp field staff. All members of the field personnel are called in for conference at district headquarters several times each year...and usually to the factory in Michigan during the summer for additional meetings and discussions.

Thus is maintained an informed field staff, available for consultation at any time and at any place—a staff whose sole responsibility in selling Camp supports is to foster that entente with the profession which S. H. Camp & Company has treasured jealously in the past twenty-seven years.

THE TREATMENT OF EARLY SYPHILIS

Basic Principles suggested by
Five University Clinics in collaboration
with the U. S. Public Health Service

- ● The use of an arsphenamine as the foundation of the treatment.
- ● The use of a heavy metal as an adjuvant (preferably bismuth intramuscularly).
- ● Continuation of treatment without a rest period for a period of a year after all symptoms and signs of the disease have disappeared.

The use of Neo-arsphenamine Merck in the Continuous Method of Treatment may be relied upon to produce satisfactory results.

NAME____________________ M. D. CITY____________________

STREET____________________ STATE____________________

FOR

Children's Colds

In prescribing Benzedrine* Inhaler for children's head colds, you are providing a first-aid remedy which may prove of constant service throughout the winter months.

At the first sign of a cold the child is instructed to use the inhaler to reduce congestion and to maintain the patency of the nasal passages. Benzedrine Inhaler has been shown to have no deleterious effect even on the delicate cilia of the nose. Since it is volatile it penetrates to areas usually inaccessible to liquid inhalants, and there is no oil to be aspirated and become a potential source of later trouble by accumulating in the lungs. (Graef: Am. J. of Path.; Vol. xi, No. 5, Sept. 1935.)

For the adult members of the family, Benzedrine Inhaler is as useful as it is for your young patients. Secondary reactions "are so infrequent and so mild as to be virtually negligible"(Scarano: Med. Record; Dec. 5, 1934); and even in very young children over-stimulation and other undesirable reactions do not occur with the proper dosage.

ESTABLISHED 1841

MULFORD
VACCINE VIRUS - SMALLPOX VACCINE

SMALLPOX VACCINE, Mulford

SMALLPOX VACCINE MULFORD has pioneered in the biological field. Since its introduction in 1898, continued research and the accumulating experience of thirty-eight years' production have developed a product in keeping with current scientific knowledge.

There has been progress in product and package—from the technic of scab vaccination, through the old-fashioned dry ivory points, dry glass points, glycerinized glass points, to the Mulford Improved Capillary Tube-Point. The latter is a sterile, sealed vaccine container and inoculating instrument all in one, ready for immediate use with any of the approved technics—multiple pressure, puncture or scratch.

Smallpox Vaccine Mulford is subjected to exhaustive tests which assure its potency and purity before release. For this reason it produces a high percentage of successful vaccinations in non-immune individuals. It is supplied in Capillary Tubes, 5's and 10's, and in Improved Capillary Tube-Points, singles, 5's and 10's.

carbolic acid and the labeling failing to state the word "Poison," suitable treatments for use in case of accidental personal injury, and the common name of the dangerous caustic or corosive substance contained in the product.

Two patent medicines found themselves in the toils of the law. "Kojene," was a water solution of oxyquinolin sulphate and sulphur dioxid flavored with wintergreen, falsely and fraudulently represented as a treatment for pyorrhea, trench mouth, gingivitis, soft, spongy, bleeding gums, old sores, skin affections, tonsillitis, pharyngitis, most common throat infections, for relieving soreness and preventing infection. "Bowman's Lax-tiv Pills," was merely a combination of plant laxatives including aloe, but bore broad claims for the restoration of health and the prevention of disease.

Good education is not a by-product of listless living.

For Acidity and Allied Conditions, we suggest ADAMS SPRINGS MINERAL WATER

● MANY physicians recommend the water in conjunction with the treatment of stomach, liver and kidney trouble.

ADAMS MINERAL SPRINGS is one of the seven known iron and maganese bi-carbonate springs in the world, and the only one in Western America.

It is not a cure-all, but it overcomes acid excesses in the body, and is a very mild but wonderfully effective eliminator. The bowels function without spasm, the kidney output is greatly increased, and there is *marked* drainage of bile from the gall bladder and liver.

There is also some constitutional upset for a few days, particularly in gall bladder cases. But this is soon over and your patient begins to show improvement and is now in condition to profit by any medication you may prescribe. If the case is an operative one, you have improved your patient and made of him a better risk.

We will be pleased to cooperate in any way whatever, and samples of water are yours for the asking.

The Pacific Rattlesnake.*—Judging from experience on two annual outings with the Sierra Club, a few rattlesnakes are almost certain to be encountered on these trips, arousing uneasiness and fear. It is the purpose of this article to discuss pertinent facts concerning the occurrence, habits, and characteristics of these reptiles, precautions against being bitten and emergency treatment of bites, and to correct some common errors of belief; since more accurate knowledge allays fear and minimizes danger.

Rattlesnakes are the only poisonous snakes of any consequence in California. All other snakes occurring in the state are harmless, if not, as in many cases, distinctly beneficial, and the members of an outdoor organization should be among the leaders in their protection. Snakes are not "slimy," and they are not necessarily "cold," their temperature varying with the immediate environment. There is in fact scarcely any animal cleaner to handle than a snake. Even rattlesnakes are useful destroyers of rodents; but they are sufficiently dangerous to the human race that one can scarcely plead for their conservation.

A number of species and subspecies—i. e., a number of fairly distinct kinds—of rattlesnakes occur within the geographical boundaries of California. Most of them are found only in the warmer and drier regions, some only in the "desert" localities, while but a single one occurs in the northern part of the state and in the Sierra Nevada proper. This is the Pacific rattlesnake. It has been long known to science as Crotalus oreganus; but more recently as a result of the careful studies of L. M. Klauber of San Diego, it has been shown to be a variety, or subspecies, of the widespread prairies rattlesnake, and accordingly is designated by him as Crotalus confluentus oreganus. It may still be called the Pacific rattlesnake, and it "occupies all parts of California except the Colorado and Mojave deserts—from sea level up at least to an altitude of 8,600 feet in the Sierra Nevada." I believe but few, however, are found in the Sierra Nevada above 8,000, though an occasional stray individual may occur up to as much as 9,000 feet in favorable locations, such as southerly exposures. In San Diego County, Klauber says, it occurs on the tops of the highest peaks. One was killed by members of the 1931 outing party at the edge of the meadow just below the Neall Lake Camp of that year. A party of more than 200 persons is almost certain to find some in areas visited below 8,000 feet. Pate Valley seems to be a rather favorable locality.

This species may be designated as moderately large, possibly, though not commonly, up to five feet in length. A mature specimen is not thick-bodied in proportion to its length, a recorded forty-two-inch individual being four inches in circumference. It is rather dark in general coloration, with a well-marked diamond pattern on the body, and with yellow, olive-green, brown, or gray ground coloration.

While a rattler of the size attained by the Pacific rattlesnake must be accounted a dangerous reptile, an inventory of its characteristics contains much that is reassuring to the cool-headed mountaineer capable of intelligent thinking. It is well, first of all, to realize that rattlesnakes are never hunting humans—they do not hunt trouble. While they seem to place some reliance in their powers of defense, and thus in some instances stand their ground if disturbed, they do not show the calm indifference of the skunk to threatened danger, but generally seek safety in retreat. The act of striking is often, if not usually, a reaction of fear rather than of anger or pure viciousness. In fact, an ordinary harmless racer almost invariably puts up a wilder and apparently more vicious fight than a rattler.

(Continued on Page 44)

KARO
BEFORE AND AFTER OPERATIONS

WATER BALANCE
(24 HOURS)

Intake	*Outgo*
Drinking Water (600 cc.)	**Urine (800 cc.)**
Beverages (600 cc.)	**Skin (700 cc.)**
Solid Food (700 cc.)	**Lungs (600 cc.)**
Metabolic Water (300 cc.)	**Feces (100 cc.)**

SURGEONS prepare patients pre-operatively to prevent acidosis and post-operatively to protect nutrition. Karo serves this dual purpose. Given with a soft diet before operation the patient will better resist surgical acidosis. And Karo forced with fluids after operation provides vital energy the patient craves.

Acidosis accompanies anesthesia and toxicity follows surgical trauma. Their effects may be moderated by the administration of Karo. It enriches the glycogen reserves thereby helping to prevent surgical acidosis, decrease post-anesthetic vomiting, stimulate the strained heart and combat shock.

After operation nutrition wanes when the patient cannot tolerate food. Karo with fluids helps maintain the water balance of the body and tides the patient over with basal energy. Karo provides 60 calories per tablespoon. It is relished added to milk, fruit juices and vegetable waters. Karo is a mixture of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor), well tolerated, not readily fermentable, and effectively utilized.

ACCEPTED
AMERICAN MEDICAL ASSN.

Corn Products Consulting Service for Physicians is available for further clinical information regarding Karo. Please Address: Corn Products Sales Company, Dept. SJ-9, 17 Battery Place, New York City.

"Two Generations of Appliance Makers"

(Continued from Page 42)

While general statements are difficult to make, because there are both specific and individual differences in rattlesnakes, the species under discussion is not the most excitable or dangerous. That distinction seems to belong to the desert diamond rattlesnake (Crotalus atrox) of Texas, Arizona, and the deserts of southeastern California. The Pacific rattlesnake in southern California is given credit for a very inoffensive disposition by Dr. Joseph Grinnell, who says: "In all our experience the rattlers of this region proved to be mild-mannered and inoffensive, seeking to make their escape in every instance, and only striking when worried to the last degree. Neither myself nor my companions had any 'narrow escapes' from being bitten that we were aware of." The following excellent advice from the same source as the above quotation may well be thoughtfully considered by outing enthusiasts: "There are lots of interesting things to be learned about rattlesnakes in their native haunts, and we would urge students having the opportunity to avail themselves of it by finding out everything possible. The only danger we can conceive of, that when a rattler is stepped upon unawares, is past as soon as you have caught sight of the reptile. You are at once on your guard. Retain your common sense. Don't go into hysterics and think you must batter the snake to death at once. For it won't run after you! Exercise reasonable caution, give your curiosity full sway, and see what you can find out."

Rattlers are popularly supposed to seek out exposed situations, where they may bask for hours in the sun, and yet those club members who were in Pate Valley in 1931 will remember that one was killed there by only a few minutes' exposure to the midday sun on a sandy area. The fact is that rattlesnakes are primarily nocturnal, or at least crepuscular, especially during the warmest months of the year. At these times they lie in shaded situations during the hottest period of the day, avoiding bare earth and exposed rock, where

the accumulated heat would soon be fatal. In spring and autumn, on the other hand, when the nights are too cold for activity, they warm themselves by day on sand or rocks in more or less exposed places, where they can withdraw to partial shade if the heat becomes too great. It is in cool periods, therefore, that mountaineers need to exercise the most care in hiking or climbing steep grades or more precipitous rocks where the danger of placing a hand on a rattler, or of meeting one literally "face to face" is greatest.

There is but little danger in hiking over level ground, or up slopes on which the hands need not be used to assist, so long as the hiker has even an ordinary amount of clothing on the lower limbs. The usual height at which the strike lands, from level ground, is about ankle to army shoe-top height. Therefore, oxfords or low sneakers afford but little protection. Basketball shoes give a small measure of protection, army or other leather shoes of that height considerably more. Canvas leggings offer additional safety, while fourteen-inch boots are practically completely safe, and leather puttees are as so much armor plate where the rattler is concerned. Perhaps no better evidence of the comparative lack of danger from rattlers is needed than the impunity with which so many of our hikers go about in shorts or bathing suits. The writer, after living many years in rattlesnake territory without ever having been struck at, still prefers the feeling of safety which comes from the wearing of leather boots or shoes.

Many are the stories which go the rounds as to these (and other) reptiles crawling into campers' beds, occupied or unoccupied, but this writer has yet to authenticate any such case, and he has spent many a night on the ground in the country of the rattlesnake. A friend who was a member of a Sierra Club annual outing some years ago tells of a rattlesnake being found in boughs placed beneath the bed of certain members of the party. Happily, such cases must be

(Continued from Preceding Page)

rare. If perchance you have heard that a horsehair rope placed on the ground so as to encircle the bed is a protection against rattlers, you may as well know that it is futile. A rattlesnake will crawl right over such a barrier—and why not? It can crawl with impunity across a barrier of cactus.

Rattlesnakes are often found at rest in a nice, neat coil, and so are popularly reported to have been "coiled to strike." That this is far from the truth may be readily demonstrated if only a little calm observation is made to replace hysteria. Disturb one rudely and the first thing it does is to rapidly unloose these coils, quickly assuming a posture which will be readily recognized as a fighting pose. If really angry or excited, the anterior one-third of the body is reared somewhat above the ground and bent into sharp but graceful curves like a letter "S," or a succession of them—that each bend is in the opposite direction from the one before or behind. If reared high, and very threatening, the head and neck may be tilted downward again from a higher curve farther back. The tongue plays in and out, and the rattle sounds a once-heard-never-forgotten buzz. The rattle may be within the curves and loops, or readily visible somewhere outside them. The posterior two-thirds of the body will be seen to be in coils or loops forming a firm base of support from which to launch the strike. A short stroke can be quickly made from almost any position by drawing the head back a bit, but the longest and most effective strike is doubtless that from the position described.

Now, a rattlesnake can not leap, and can not strike its own length. Its most effective stroke is the shortest, both the power that goes into it and the accuracy of aim diminishing with distance. One-third of its own length is about the greatest reasonably effective range, and certainly beyond half its length lies safety. Therefore you do not need a "ten-foot pole" with which to kill, or experiment with, a rattler.

Doctors Soiland, Costolow and Meland

An institution devoted to the study and treatment of malignant or benign tumors and allied disease by radiological and electro-surgical methods.

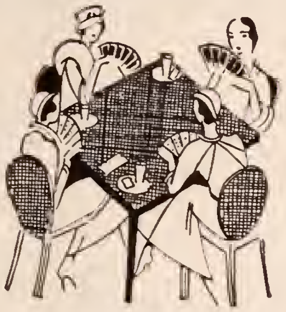
A. H. WARNER, Ph.D.,
Physicist

In a recent story in a popular weekly magazine a well-known writer drew for his readers a word-picture of a vicious brute of a rattlesnake, coiled ready for action, its head swinging from side to side, mouth wide open, and hissing venomously. In fact (and the writer hopes the reader will verify this at the next opportunity), the head swings only so much as is necessary to keep a watchful eye on the moving object which engages its attention. The rattlesnake never opens its mouth before launching the strike and the writer has never heard this kind of snake hiss. Of course, the hero of the story "blew off" the head of this dragon with his trusty six-shooter in spite of its active movements.

The "bite" of the rattlesnake is a combination of acts which takes place with astonishing speed, often too fast for the eye to follow. As the head moves forward the mouth is opened widely, an action which erects the fangs from their resting position against the roof of the mouth so that they point forward. The jaws are capable of opening until the lower jaw almost forms a line with the upper, instead of an acute or even obtuse angle. The forward-pointing fangs thus literally stab the victim, and are partially imbedded if the aim be accurate. A convulsive closing movement or "bite" instantly follows, and is, usually, as quickly released. But this biting movement compresses by muscular action the venom glands of the upper jaw, and portions of venom pass along the ducts to the bases of the hollow fangs and through the fangs into the wound, exactly as a hypodermic injection is made. Nature gave the rattlesnake a hypodermic needle long before man invented it. Removal of the fangs renders a rattlesnake comparatively harmless, but only temporarily. New fangs in a short time move into position to replace those extracted, a provision of nature to care for the losses which normally occur in striking prey. There is no method of removal of the poison glands. To take them out by an operation would nearly destroy the sides of the head.



MEETING of the BOARD of DIRECTORS

When women gather for conversation and bridge, that is when these directors of home life often make their decisions.

As an organization whose products are delivered into thousands of California homes, we have a keen appreciation of the value of this kind of "bridge table" conversation. We are often discussed. But, just as often the words of you—the family doctor and health counselor—are repeated.

It behooves Golden State to see to it that our products and services are so consistently above standard, so dependable and so worthwhile, that none but words of praise are linked with our name.

We believe there is a mutual value when the conversation links the advice of the doctor and the name Golden State Milk.

Perhaps you should, for your part, know more about the ideas and ideal of the Golden State organization; more about the research laboratories maintained; more about the quality safeguards which surround every Golden State dairy product.

May we suggest that one way to get acquainted would be to ask our deliveryman to serve your home with Golden State Milk. The milk itself will give you a new idea of how fine, how tasty, how full and rich milk can be. Then make it a point to visit your Golden State Milk plant. It will be time well and profitably invested.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.

2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.

3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.

4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.

5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

VITAMINS IN CANNED FOODS

III. VITAMIN A

• The most characteristic evidence of severe human vitamin A deficiency, and one which is increasingly rare in this country, is xerophthalmia. Night-blindness, one of the manifestations that usually precedes xerophthalmia, has been recognized as a deficiency disease since the time of Hippocrates who described the disease, and its cure by eating liver. Infrequent reports of this disorder, however, still appear in the American literature. Most if not all of the symptoms accompanying a deficiency of vitamin A are thought to be the result of an impairment of the epithelial tissue (1). In this connection, a new method for the quantitative determination of this vitamin is based on the keratinization of germinal epithelia (2).

That vitamin A exerts an influence on the growth of human infants and children is also generally accepted.

As early as 1919, a relationship between vitamin A in plant foods and plant pigments was postulated. Research since that date has indicated that beta-carotene and some related compounds may be considered as provitamin A (3).

The vitamin A potency of fruits and vegetables is apparently due to their carotene content, since vitamin A as such has never been found in plant tissue. Ingested carotene is believed to be converted into vitamin A by enzyme action in the liver of the animal (4), in which organ the vitamin is stored.

Vitamin A in the form of carotene may be present in yellow, green or red pigmented fruits and vegetables—in the two latter cases, the yellow color of carotene being masked by other pigments present. Color alone, therefore, is not always a reliable index of potential vitamin A potency.

Both vitamin A and carotene are relatively stable to heat but are subject to destruction by oxidation. However, foods of both animal and plant origin, when canned by modern methods, have been found to retain their vitamin A potencies in high degree (5).

In fact, in some instances, practically no loss of vitamin A potency can be detected by formal bio-assays (6).

Commercially canned foods, therefore, may be used with the knowledge that they will contribute to the American dietary amounts of vitamin A entirely consistent with those contained in the raw materials from which they were prepared.

This is the sixteenth in a series of monthly articles, which will summarize, for your convenience, the conclusions about canned foods which authorities in nutritional research have reached. We want to make this series valuable to you, and so we ask your help. Will you tell us on a post card addressed to the American Can Company, New York, N. Y., what phases of canned foods knowledge are of greatest interest to you? Your suggestions will determine the subject matter of future articles.

The Seal of Acceptance denotes that the statements in this advertisement are acceptable to the Committee on Foods of the American Medical Association.

½ or 1 c. c.? — DIPHTHERIA TOXOID
Alum Precipitated

Reactions which first followed the use of Diphtheria Toxoid (Alum Precipitated) were thought possibly due to the use of the ½ c. c. dose. As there is little if any added discomfort to the one c. c. dose Cutter's half c. c. dose was removed from the market and replaced by a full one c. c. dose. The fact that such reactions are now practically nil following the use of Cutter's Alum Precipitated Toxoid indicate the advantage of the larger dose.

There is no question of concentration as the size of the dose is determined simply by the amount of diluent added. The greater volume properly dilutes the alum with lessened chance for reaction.

Western Electric New Audiometer

MODEL 6A

The generally acknowledged standard for audiometric measurements — supersedes Model 2A — now incorporates the following improvements:

- Employs a heterodyne oscillator so that it can be set for *any frequency* up to 10,000 cycles per second.
- Improved facilities for both air and bone conduction measurements.
- No batteries required—operates on either alternating or direct current.
- Reduced size and weight—more elegantly finished.
- Price—$275 complete.
- Additional equipment may be furnished designed to measure the amplification necessary for a patient to obtain speech intelligibility. Indispensable in prescribing hearing aids.

LIVERMORE SANITARIUM

The Hydropathic Department devoted to the treatment of general diseases excluding surgical and acute infectious cases. Special attention given functional and organic nervous diseases. A well equipped clinical laboratory and modern X-ray Department are in use for diagnosis.

The Cottage Department (for mental patients) has its own facilities for hydropathic and other treatments. It consists of small cottages with homelike surroundings, permitting the segregation of patients in accordance with the type of psychosis. Also bungalows for individual patients, offering the highest class of accommodation with privacy and comfort.

GENERAL FEATURES

1. Climatic advantages not excelled in United States. Beautiful grounds and attractive surrounding country.
2. Indoor and outdoor gymnastics under the charge of an athletic director. An excellent Occupational Department.
3. A resident medical staff. A large and well trained nursing staff so that each patient is given careful individual attention.

Quinolor Lubricant.—In Quinolor Lubricant, the Squibb Laboratories are offering a new antiseptic lubricating jelly whose field of service is especially broad. It may be used as a simple household application or for scientific employment in the operating room. It is bacteriostatic and antiseptic, does not become rancid, is non-irritating and not injurious to the most delicate tissues. Upon the gloved finger for digital examination or upon catheters, sounds, nozzles, tubes or any similar instrument, it facilitates and renders painless their introduction. As an antiseptic, it may be employed as a protective dressing for superficial lesions.

Quinolor Lubricant yields a clear zone of 5 to 6 millimeters when subjected to the "cup test" against Staphylococcus aureus. Its antiseptic power is due to the inclusion of 0.025 per cent of a new antiseptic substance. Quinolor, which is produced by the chlorination of hydroxy-quinoline. Whether applied to moist or dry surface, Quinolor Lubricant spreads readily and smoothly and adheres tenaciously. It is soluble in water, may be removed without the use of soap, and does not stain clothing or linen.

Mead Johnson & Company Coöperates with the American Medical Association Council.—Voluntarily, we market only Council-accepted products because we have faith in the principles for which the American Medical Association Council on Pharmacy and Chemistry (and the Council on Foods) stand. We have witnessed the three decades during which the Council has brought order out of chaos in the pharmaceutical field. For over thirty years it has stood—alone and unafraid—between the medical profession and unprincipled makers of proprietary preparations.

The Council verifies the composition and analysis of products, and substantiates the claims of manufacturers. By standardizing nomenclature and disapproving therapeutically suggestive trade names, it discourages shotgun therapy and self-medication. It is the only body representing the medical profession that checks inaccurate and unwarranted claims on circulars and advertising as well as on packages and labels.

The Council coöperates, through the N. N. R. and in other ways, with the United States Pharmacopeia Board, testing and evaluating scores of new products which appear during the ten-year interim between pharmacopoeial revisions.

We are conscious of the fact that the Council has at times been criticized both in and out of the medical profession. We hold no brief for perfection in any human agency. But we subscribe to the fact that the work of the Council is sound in principle; and in this high-pressure day and age, we shudder to think of a return to the proprietary-medicine-quack-nostrum conditions of over thirty years ago, when there was Babel instead of Council.

AVAILABLE THROUGH ALL PHARMACIES

EMMENIN

The orally active, oestrogenic placental extract elaborated by Dr. J. B. Collip, Department of Biochemistry, McGill University.
(Canadian Medical Association Journal, February, 1930.)

IMPORTANT ANNOUNCEMENT . . .

By an improved technique developed in our laboratories, we have been able to render Emmenin entirely free from disagreeable taste and odor. This has been accomplished without loss of therapeutic activity, and the potency is ensured by carefully controlled biological assay.

DETAILS ON REQUEST

Emmenin is biologically assayed and standardized under direct control of the Department of Biochemistry, McGill University.

Chairman, Adolph A. Kutzmann, 1930 Wilshire Boulevard, Los Angeles.
Secretary, Lloyd E. Kindall, 400 Twenty-ninth Street, Oakland.

Officers of County Medical Associations

Alameda County Medical Association
2404 Broadway, Oakland
President, W. E. Mitchell, 2068 Allston Way, Berkeley.
Secretary, Gertrude Moore, 2404 Broadway, Oakland.

Butte County Medical Society
President, Leslie Freudenthal, Gridley.
Secretary, J. O. Chiapella, 131 Broadway, Chico.

Contra Costa County Medical Society
President, Harry G. Ford, 314 Tenth Street, Richmond.
Secretary, Thomas J. Dozier, 202 G Street, Antioch.

Fresno County Medical Society
President, Kenneth Staniford, 904 Mattei Bldg., Fresno.
Secretary, Henry A. Randel, Box 2308, Fresno.

Humboldt County Medical Society
President, Joseph S. Woolford, 350 E Street, Eureka.
Secretary, L. A. Wing, Eureka.

Imperial County Medical Society
President, Floyd A. Burger, Box 193, El Centro.
Secretary, Merritt C. Canfield, 204 Professional Building, El Centro.

Kern County Medical Society
President, L. H. Fox, 2025 Eighteenth Street, Bakersfield.
Secretary, C. S. Compton, 1911 Seventeenth Street, Bakersfield.

Kings County Medical Society
President, William F. Chamlee, Hanford.
Secretary, William A. Johnstone, Hanford.

Lassen-Plumas-Modoc County Medical Society
President, C. I. Burnett, Susanville.
Secretary, Fred J. Davis, Jr., Westwood.

Los Angeles County Medical Association
1925 Wilshire Boulevard
President, Harlan Shoemaker, 1930 Wilshire Boulevard, Los Angeles.
Secretary, E. Vincent Askey, 1925 Wilshire Boulevard, Los Angeles.

Marin County Medical Society
President, J. O. Hawkins, Cheda Building, San Rafael.
Secretary, Carl W. Clark, Albert Building, San Rafael.

Mendocino-Lake County Medical Society
President, Rudolph B. Toller, Talmage.
Secretary, J. J. Kirwin, Ukiah.

Merced County Medical Society
President, J. S. Webster, Mariposa.
Secretary, Fred O. Lien, Shaffer Building, Merced.

Monterey County Medical Society
President, John A. Merrill, 308 Spazier Building, Monterey.
Secretary, E. F. Kehr, Drawer DD, Carmel.

Napa County Medical Society
President, Laurence Welti, 1130 First Street, Napa.
Secretary, M. M. Booth, 1379 Main Street, St. Helena.

Orange County Medical Society
President, John D. Ball, 414 Spurgeon Building, Santa Ana.
Secretary, Glenn Curtis, 323 So. Pomona Street, Brea.

Placer County Medical Society
President, Louis E. Jones, Roseville.
Secretary, R. A. Peers, Colfax.

Riverside County Medical Society
President, E. P. Miller, 3780 Twelfth Street, Riverside.
Secretary, T. A. Card, Glenwood Block, Riverside.

Sacramento Society for Medical Improvement
President, Frank A. MacDonald, 822 Medico-Dental Building, Sacramento.
Secretary, Norris Jones, 1127 Eleventh Street, Sacramento.

San Benito County Medical Society
President, L. C. Hull, Hollister.
Secretary, L. E. Smith, Hollister.

San Bernardino County Medical Society
President, D. C. Mock, 215 Cajon Street, Redlands.
Secretary, A. E. Varden, 575 Fifth Street, San Bernardino.

San Diego County Medical Society
Fourteenth Floor, Medico-Dental Building, 233 A Street, San Diego
President, Benjamin F. Eager, 711 Medico-Dental Building, 233 A Street, San Diego.
Secretary, Winston C. Crabtree, 14th Floor, Medico-Dental Building, 233 A Street, San Diego.

San Francisco County Medical Society
2180 Washington Street, San Francisco
President, Philip K. Gilman, 2000 Van Ness Avenue, San Francisco.
Secretary, Stanley H. Mentzer, 2180 Washington Street, San Francisco.

San Joaquin County Medical Society
President, C. A. Broaddus, 907 Medico-Dental Building, Stockton.
Secretary, George H. Rohrbacher, Medico-Dental Building, Stockton.

San Luis Obispo County Medical Society
President, Lyman T. Wade, 759 Monterey Street, San Luis Obispo.
Secretary, E. D. Anderson, 1120 Morro Street, San Luis Obispo.

(Roster lists continued on advertising page 6)

San Mateo County Medical Society
President, Olin M. Holmes, 23 Second Street, San Mateo.
Secretary, J. Garwood Bridgman, 205 Third Avenue, San Mateo.

Santa Barbara County Medical Society
President, P. A. Gray, 317 West Pueblo Street, Santa Barbara.
Secretary, William H. Eaton, Health Department, Santa Barbara.

Santa Clara County Medical Society
President, R. Stanley Kneeshaw, 404 Medico-Dental Building, San Jose.
Secretary, Leslie B. Magoon, Medico-Dental Building, San Jose.
Assistant Secretary, Daniel Bilker, Medico-Dental Building, San Jose.

Santa Cruz County Medical Society
President, Frank E. Blaisdell, 409 E. Third Street, Watsonville.
Secretary, Samuel B. Randall, Farmers and Merchants Natl. Bank Bldg., Santa Cruz.

Shasta County Medical Society
President, M. D. Pratt, Fall River Mills.
Secretary, F. H. Olberg, Craddock Building, Redding.

Siskiyou County Medical Society
President, C. C. Dickinson, McCloud.
Secretary, E. F. Carlson, Fort Jones.

Solano County Medical Society
President, A. E. Chappell, 727 Sonoma Street, Vallejo.
Secretary, J. W. Green, Box 539, Vallejo.

Sonoma County Medical Society
President, Paul T. Quarry, 213A Exchange Avenue, Santa Rosa.
Secretary, C. M. Carlson, 1055 Fourth Street, Santa Rosa.

Stanislaus County Medical Society
President, Hans Hartman, 1005 L Street, Modesto.
Secretary, E. F. Hagedorn. Box 834, Modesto.

Tehama County Medical Society
President, Arthur H. Meuser, Corning
Secretary, F. J. Bailey, Red Bluff.

Tulare County Medical Society
President, J. C. McClure, Lindsay.
Secretary, Karl F. Weiss, Security First National Bank Building, Visalia.

Ventura County Medical Society
President, Fred A. Shore, 704 E. Santa Clara Street, Ventura.
Secretary, A. A. Morrison, 625 Main Street, Santa Paula.

Yolo-Colusa-Glenn County Medical Society
President, T. E. Cooper, Davis.
Secretary, Ray E. Nichols. Woodland.

Yuba-Sutter County Medical Society
President, Francis P. Wisner, 715 Hart Building. Marysville.
Secretary, Fred W. Didier, Wheatland.

Trade-mark Reg. U. S. Pat. Off.

WITH COD LIVER OIL

Accepted American Medical Assn Council on Pharmacy and Chemistry

NEW LARGE BOTTLE— NO CHANGE IN PRICE

THE oily consistency associated with plain cod liver oil is lacking in MALTINE WITH COD LIVER OIL.★ The natural, wholesome flavor of the Maltine predominates and is indicative of the exceptional nutritional values of the cereals from which it is made. For this reason, many physicians throughout the United States rely on this 61-year-old product as a pleasant and palatable means of administering the cod liver oil vitamins A and D. It also contains vitamins B and G not supplied when plain cod liver oil is administered. The Maltine Company, 60 Hudson Street, New York City.

★ *Maltine 70%, cod liver oil 30%*

CO-OPERATE WITH YOUR ADVERTISERS

California and Western Medicine, the official publication of your Association, is made possible in part by reason of the coöperation of business firms and institutions who use advertising space. Their purpose is to direct attention to their products and services to present and future patrons.

Members and readers are urged to give preference to and to patronize these advertisers. When ordering goods, mention California and Western Medicine.

This coöperation will please the advertiser, increase advertising income, and enable your Association to increase the value of this Journal to members and readers.

A SERVICE AGENCY—FOR READERS

The Journal of the California State Medical Association and the Coöperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital, or we will refer your request to the proper department of the A. M. A. for reply.

We invite and urge you to use this Service. It is absolutely *free* to every member of the California and Nevada Associations. The Coöperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in California and Western Medicine, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This A. M. A. Service Bureau will give you the information. Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to write direct to the Coöperative Medical Advertising Bureau, 535 N. Dearborn Street, Chicago, Illinois. California and Western Medicine and the A. M. A. Service Bureau desire to serve *you*.

THE NEW YORK POLYCLINIC
MEDICAL SCHOOL AND HOSPITAL
(Organized 1881)
(The Pioneer Post-Graduate Medical Institution in America)

TRAUMATIC SURGERY
including
General Surgery, Orthopedic Surgery, Physical Therapy, Anatomical Review and Operative Surgery on the Cadaver.

PHYSICAL THERAPY
Lectures and demonstrations in electrotherapy, electrodiagnosis, and minor electrosurgery; light therapy; hydro- and thermotherapy, including fever therapy; massage and therapeutic exercise. Active clinical work in treatment of medical and surgical conditions.

FOR INFORMATION ADDRESS
MEDICAL EXECUTIVE OFFICER 345 West 50th Street, New York City

SUMMER COURSE IN
OPERATIVE SURGERY OF THE ABDOMEN
SEPTEMBER 22 to 30, 1936
Especial attention will be given to the latest development in the surgery of the Stomach, Gall-Bladder, Intestines, Colon, and Rectum. A brief review will be given of surgical anatomy of the various regions, with demonstration on carefully dissected cadavers. The work will consist of lectures, laboratory work on cadavers and fresh human material, and demonstrations and assisting on the living. Fee, $125.

A. J. REMMEL, M. D., *Director of Operative Surgery* 1535 JACKSON STREET, SAN FRANCISCO

Test Orange and Tomato Juice for Their Vitamin C Value (by Bureau of Home Economics, United States Department of Agriculture, Washington).—Orange juice contains from two to three times as much vitamin C as tomato juice. Either of the juices lose vitamin C if allowed to stand before using. These results are announced by workers in the Bureau of Home Economics, United States Department of Agriculture, in an article published on September 5 in the *Journal of Home Economics*. The Bureau points out, however, that when tomato prices are much lower than orange prices, it may be possible to get as much or more vitamin C protection per dollar from tomatoes.

The tests included both chemical analysis and feeding trials of four varieties of oranges, two from California and two from Florida—fresh pressed juice of tomatoes and juice from a brand of commercial canned tomatoes. The juice of the California Navel oranges was slightly richer than the others, but some of the others were enough juicier so that the juice from a fruit of equal size gave as good or better protection. To obtain the same protection from tomato juice it would be necessary to give two or three times as much juice.

The investigators, Esther Peterson Daniel, Mary H. Kennedy, and Hazel E. Munsell, found that the canned tomatoes which they tested contained as much vitamin C as the fresh sample. These tomatoes were grown in different section of the country and, since there is a loss of vitamin C in canning, these results raise the question of the effect of soil and climate upon the amount of vitamin C formed in the plant.

The common household custom of squeezing orange juice at night to serve at breakfast causes a loss of 10 per cent or more of its vitamin C value, even though it stands covered in a refrigerator. Tomato juice from fresh or canned tomatoes also deteriorates when allowed to stand exposed to the air. This may amount to as much as a 40 per cent loss if the juice stands for several days.

Our chief enemies at present are heart disease, cancer, pneumonia, tuberculosis, and syphilis. If the full facts were known, as Doctor Osler said, syphilis would probably come first. Syphilis is the biggest killing disease in the community. It and tuberculosis are undoubtedly the greatest present contributors to the total mortality prior to the approach of old age. By the removal of tuberculosis and syphilis, most of the preventable deaths from the age of 15 to 65 would be avoided. Sir Arthur Newsholme, M. D.

COOK COUNTY GRADUATE SCHOOL OF MEDICINE
(In affiliation with Cook County Hospital)
Announces Continuous Courses

MEDICINE—Informal Course first of every week; Intensive Personal Courses.
SURGERY—General Course, One, Two, Three and Six Months; Intensive Course, Surgical Technique, every two weeks; Special Courses.
GYNECOLOGY—Three Months Course; Intensive Two Weeks Course, starting October 19.
FRACTURES AND TRAUMATIC SURGERY—Informal Practical Courses; Intensive Ten-Day Course, starting February, 1937.
EAR, NOSE AND THROAT—Informal Course; Personal Courses; Intensive Ten Day Course, starting April, 1937.
OPHTHALMOLOGY—Intensive Two Weeks Course, starting April, 1937.
UROLOGY—General Course, Two Months; Intensive Course, Two Weeks; Special Courses.
CYSTOSCOPY—Intensive Course every two weeks (attendance limited).

General, Intensive, and Special Courses in Obstetrics, Pediatrics, Tuberculosis, Roentgenology, Electrocardiography, Dermatology and Syphilology, Pathology, Neurology, Topographical and Surgical Anatomy, Physical Therapy, Gastro-Enterology, Allergy, Rectal Diseases, Varicose Veins, and Psychiatry.

TEACHING FACULTY—ATTENDING STAFF OF COOK COUNTY HOSPITAL
Address: Registrar, 427 South Honore Street, Chicago, Ill.

The pleasures of the senses pass quickly; those of the heart become sorrows; but those of the mind are with us even to the end of our journey.—Spanish Proverb.

In the nature of things youth cannot be aware of its latent powers.—Leon J. Richardson.

WOMAN M. D. EXPERIENCED IN MEDICAL LITERARY and editorial work, available for complete or partial preparation of manuscripts or textbooks, studies of case records, etc. Good facilities for medical literary research. Reads French and German. A. Z. McNamara, 19106 Chase St., North Los Angeles, California.

FOR LEASE—SUITABLE FOR PHYSICIAN OR DENTIST as office, also residence, commodious seven-room lower flat, large basement with furnace, west side of Larkin Street, between Union and Filbert, San Francisco. Very desirable surroundings. Agents, H. Neuhaus and Son, 785 Market Street, San Francisco, California.

Blood Pressure, Hot Dogs, and Merry-Go-Rounds. The old-fashioned medicine man is slowly disappearing from sideshows and county fairs, but today a new charlatan is taking his place at beach resorts, fairs, and amusement parks. Equipped with a white coat, a stethoscope, and a blood-pressure instrument, these operators are capitalizing on the public's interest in blood pressure. Their main concern is collecting the ten or fifteen cents they charge per "patient."

It is evident that blood-pressure readings taken by such persons under such circumstances are of no value. The "patient" is simply being bilked, but the most harmful part of this practice is the serious consequences that may easily result in some cases, regardless of whether the information is erroneous or otherwise.

We are vigorously opposed to this misuse of medico-scientific instruments, having gone on record with the American Medical Association to this effect a year ago. Moreover, we have refused to fill large orders for Baumanometers to be used for such purposes.

This evil practice should be stopped, and we would appreciate your coöperation in reporting to us any instance that comes to your attention—especially where some definite harm has resulted to a patient. Signed: W. A. Baum Co., Inc., 460 West Thirty-fourth Street, New York.

Health! thou most august of the blessed goddesses, with thee may I spend the remainder of my life, mayest thou benignly dwell with me; for if there be any pleasure to be derived from riches, or if there be any delight bestowed on men, or respite from pains, with thee, blessed health, all these flourish and beam effulgent like the spring arising from the graces; without thee no one is happy.—Ariphron.

THE
ART OF TREATMENT
By WILLIAM R. HOUSTON

"I believe that this is one of the few medical books that have appeared in recent years which is written in a style that makes for easy reading. I might say that I sat down and read the book for an hour and a half, going ahead steadily from where I started. I was reading not only for information, the book is authoritative, but also from pure enjoyment of interesting reading."
—Dr. J. H. Musser,
Professor of Medicine, Tulane Medical School

NUTRI-AD
ARTHROPHYLL
(6)

A Nutritional Adjuvant

In a wide variety of cases involving Arthritis Deformans also Arthritic and Rheumatic disorders due to calcium deposition NUTRI-AD Arthrophyll (6) has accomplished favorable results to a degree heretofore unreported.

By making available prolific sources of organic phosphorus in a highly assimilable state it is apparent that this natural agency for increased calcium excretion has been provided. » » » » » » » »

This procedure together with inducing normal bowel elimination offers a likely solution to this stubborn and widely prevalent pathology. » » » » » » »

NUTRI-AD—ARTHROPHYLL(6) consists of the concentrates of green leafy vegetables so compounded and proportioned as to supply a maximum of phosphorus and a minimum of calcium through which the offending calcium deposits are disintegrated and excreted.

NUTRI-AD—ARTHROPHYLL(6) is available only in prescription form through the ethical medical profession. Literature gladly furnished on request.

Extraordinary advances have made it necessary to bring out a sixth edition of this text that has been an authority since 1916. Beginning with the idea that all departures from normal health are brought about by some harmful or disturbing agency, the author traces these changes back to their cause and then describes anatomical alter-

ations, functional disturbances and reactions. A most acceptable manner in which to present true pathology. Endocrine disturbances, vitamin deficiencies, and virus infections are presented in a modern light.

The text and illustrations indicate the thoroughness of revision, and the stressing of etiology characterizes the author's individuality as a teacher and investigator in pathology and makes him a distinguished authority. This sixth revision brings this text to a prominent front rank in the literature on pathology. It follows that it merits a place in every medical library.

Microbiology and Pathology for Nurses. By Charles F. Carter, M. D., Dallas, Texas. Cloth. Pp. 628, illustrated. St. Louis: C. V. Mosby Company. Price, $3.

A satisfactory and sufficiently complete manual and reference text for nurses. Quite abreast of modern knowledge. Should be valuable in every library on nurse training.

An Introduction to Materia Medica and Pharmacology. By Hugh A. McGuigan, Ph. D., M. D., University of Illinois. Cloth. Pp. 580. St. Louis: C. V. Mosby Company. Price, $2.75.

True to its title and well arranged for student nurses. Well chosen illustrations with an understandable text.

Medicine and Mankind. Edited by I. Galdston, M.D. Cloth. Pp. 217. D. Appleton-Century Company. Price, $2.

The New York Academy of Medicine has for a long time recognized an important society responsibility to enlighten the public on questions of health and medicine. It not only recognizes, but accepts and discharges that responsibility by sponsoring a series of public meetings. These meetings are addressed by men capable, experienced and well-prepared to present scientific facts in a manner that the layman can understand. A splendid example meriting emulation.

This volume contains seven of these public lectures: "How I learned about the Human Body, Benjamin P. Watson; Medicine in the Days of the Grand Monarch, Howard W. Haggard; The Contributions of the Primitive Americans to Medicine, Harlow Brooks; The Common Denominator of Disease, George Draper; Organic Background of the Mind, Foster Kennedy; The Story of the Vitamins, E. V. McCollum; The Mystery of Death, Alexis Carrel."

Aside from the excellence of these lectures they should serve as a model and stimulus to others to contribute in like manner to the education of the public.

Diabetic Manual: For Practitioners and Patients. By Edward L. Bortz, M. D., University of Pennsylvania. Cloth. Pp. 222. Illustrated. Philadelphia: F. A. Davis Company.

This manual conforms to other similar guides. It will be of assistance to every diabetic.

Tissue Immunity. By Reuben L. Kahn, D. Sc., University of Michigan. Cloth. Pp. 707. Illustrated. Baltimore: Charles C. Thomas.

This is a new text. The author requires no introduction, as he is known for his research work and the Kahn test in syphilis.

This volume presents quantitative studies on tissue immunity and correlates the results of these studies in the clinic. Immunologists have made striking discoveries in the fields of humoral and cellular immunity. Tissue immunity has been vaguely understood. The experiments here imparted seem to indicate that tissue immunity is a defensive, and not a hypersensitive reaction.

Experiments are clearly described, thereby enabling one to reproduce them for his own studies and conclusions.

The author has made a very valuable contribution to the literature on immunity.

Western Electric
New Audiometer
MODEL 6A

The generally acknowledged standard for audiometric measurements — supersedes Model 2A — now incorporates the following improvements:

- Employs a heterodyne oscillator so that it can be set for *any frequency* up to 10,000 cycles per second.
- Improved facilities for both air and bone conduction measurements.
- No batteries required—operates on either alternating or direct current.
- Reduced size and weight—more elegantly finished.
- Unique masking attachment for testing bone conduction.
- Additional equipment may be furnished designed to measure the amplification necessary for a patient to obtain speech intelligibility. Indispensable in prescribing hearing aids.

$200,000 deposited with State of Nebraska, for our members' protection.

Langley Porter, the president of the society, to study and gather data on the epidemic of poliomyelitis which at that time seemed to be prevailing in San Francisco. . . .

Conclusions.—1. San Francisco has unquestionably been the seat of an epidemic of anterior poliomyelitis from October, 1909, to October, 1910.

2. The cases ran typical clinical courses as they are ordinarily described for this disease.

3. The period of life most susceptible to this condition is between the ages of 1 and 6 years.

4. The summer months, May, June, July and August, represent the time of year that the disease is most potent.

5. Pain is a much more common symptom than was formerly described in the older textbooks.

6. It is regrettable that lumbar puncture and blood counts were done in so few cases. . . .

From an article on "Athletics and Sexual Neurasthenia" by Victor G. Vecki, M.D., San Francisco.

Man was neither born nor created to do hard work. In the Bible we are told that Adam did not feel like working until Eve felt that it was time to dress herself. . . .

Take, for instance, one of our newest sports, the automobiling. It certainly has become an actual menace. Talk about Abe Ruef, like other prisoners in San Quentin, losing their personality because of the ever present guns of the guards being trained on them! How can the San Francisco pedestrians keep their personality dodging the autocars speeding on crossings and dashing around corners? The long-suffering public could hardly be blamed should they feel some kind of satisfaction when learning that motorcar speeding causes sexual impotence. . . .

The plain truth, of which everyone can convince himself easily, however, is that horseback riding properly

(Continued on Page 17)

When Steers Had Long Horns

THE medicinal value of the glands of internal secretion was not recognized.

But times have changed, as well as cattle. Now, the therapeutic value of certain gland products is definitely established and each year adds to our knowledge in this important field of therapeutics.

To the physician prescribing gland products we urge specification of "Wilson," because it connotes a product made at the source of supply from fresh glands, processed promptly, with the aim of conserving maximum hormone activity, in a laboratory devoted exclusively to the endocrine field.

As San Francisco Moves Forward

» It is certainly no news that America has been passing through a depression.

» The James H. Barry Company, like every other business in the land, has had its problems during this trying period. And like every other enterprising American business, this company has faced those problems with honesty, patience, and resourcefulness. But most of all, with determination to GO AHEAD.

» A vast range and variety of betterments in printing technique and equipment is the result. We have not waited for the dawn of business revival to make these improvements. In the past depression years thousands of dollars have been spent annually by us, keeping pace with the many changes in our particular industry.

» Yet today, this company is embarked upon the most ambitious expansion program in its history. On or about October 15, we will occupy our own building—especially designed and engineered to suit the needs of our exacting manufacturing requirements—comprising more than 22,000 square feet, on Van Ness Avenue South near Thirteenth Street. Moreover, additional high speed printing and binding equipment is being installed.

» Perhaps it takes courage to make these huge investments. Rather, we believe, it takes FAITH. Faith in America, in our community, and in our own ability as craftsmen to give the buyers of printed matter an honest dollar's worth.

JOHN ABERCROMBIE 1780-1844

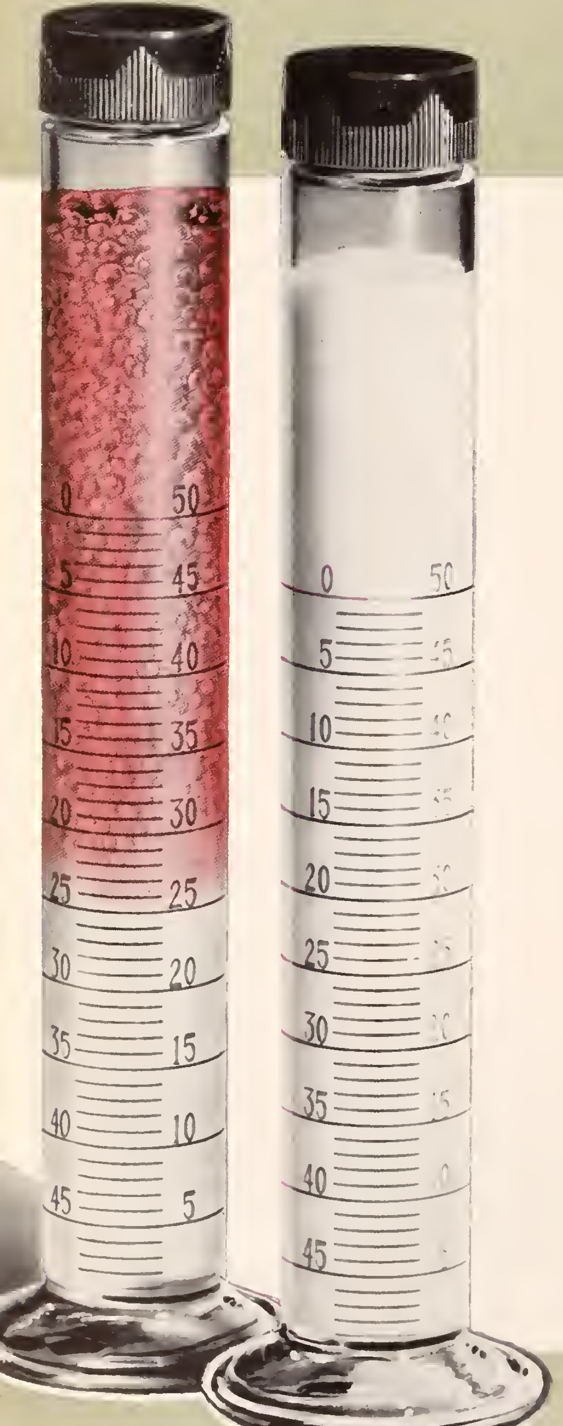
M. D. Oxford, Rector of Morischal College, Physician in Ordinary to His Majesty

Reproduced from the Collection of the Northwestern University Medical School
by Petrolagar Laboratories, Inc., Chicago

PRE·EMINENCE

John Abercrombie—1780-1844. An eminent Scotch physician. He was born at Aberdeen and graduated in medicine at Edinburgh in 1803. He practiced his profession in the Scottish Capital and soon became recognized as the first consulting physician in Scotland. Among the honors bestowed upon him were the degree of M.D. from Oxford, the rectorship of Morischal College, the vice-presidency of the Royal Society of Edinburgh, and the office of Physician in Ordinary to His Majesty for Scotland.

Petrolagar Laboratories, Inc., *through the cooperation of Northwestern University Medical School, will reproduce portraits of pioneers in the study of gastro-enterology from time to time. Additional copies of the portrait of John Abercrombie are available to members of the medical profession upon request. In like manner, other portraits will be available as they are published.*



Miscibility DEMONSTRATED

The two flasks here illustrated contain an equal amount of mineral oil. One is Petrolagar emulsion and water, the other is plain mineral oil (stained red) and water.

Although shaken vigorously, the plain oil and water separate immediately as shown in the accompanying photograph, whereas the oil in Petrolagar remains suspended. This demonstrates the miscibility of Petrolagar.

Since Petrolagar is miscible in water and mineral oil is not, it is obvious why Petrolagar readily mixes with the bowel contents. The oil, being in minute globules, has less tendency to leakage. Petrolagar promotes efficient, comfortable evacuation.

Petrolagar is a palatable emulsion of
re liquid petrolatum, (65% by volume)
d number One Silver White Kobe Agar-
ar, accepted by the Council on Pharmacy
d Chemistry of The American Medical
ssociation for treatment of constipation.

done can never be injurious to the sexual organs nor to their functions. It is quite true that the rider must sit in his saddle upon that part of the body which is by nature upholstered and constructed for that purpose. . . .

Pacific Coast Oto-Opthological Society.—During the week of Professor Fouchs' course of lectures given at the Medical Department of Stanford University, the Pacific Coast Oto-Opthological Society effected a permanent association for the advancement of their specialty. . . .

Medical Defense.—Philip Mills Jones, Secretary, Medical Society of the State of California, San Francisco, California.

Dear Doctor: I wish to express my sincere thanks to the State Medical Society for the able way in which your attorneys, W. W. Kaufman and H. A. van C. Lorchiana, handled my defense in a malpractice suit brought against me for $20,450. The jury brought in a unanimous verdict in my favor on the first ballot. . . .

From the experience which I have had, I can assure any conscientious practitioner that he need have no fear of the final outcome of a suit defended by our State Society. I am certain I had much better service than any far-away insurance concern could have given.

Wishing you success in your good work, and with many thanks, I am,
Very truly yours,
H. B. CAREY.

August 12, 1911.

There are steps in education that can be taken only after one has gained some measure of experience.—Leon J. Richardson.

A Modern Product

Of Proved Value in . . . the Endotoxic Infections

Edwenil, the polyvalent antibacterial agent, while comparatively new, has already been used so extensively that it has won the place of a leader in the treatment of the endotoxic infections such as the respiratory diseases, boils, measles, etc.

It is a stable, colloidal, protein-free (by the Biuret Test) solution for intramuscular injection.

Edwenil promptly raises resistance to the endotoxic infections but causes no detrimental reactions, either local or general. It can be used daily to advantage. Send for complete literature on

Not all nitrous oxide is of the same purity

Latest U. S. P. specifications (January, 1936) require only 95% purity in the gaseous phase on full cylinders.

For over three years Stuart has produced its Hi-Pure Nitrous Oxide, *guaranteed over 99% pure.* So far as we know, we are the only company in the United States marketing a nitrous oxide of this purity.

Since 1933, two hospitals have used Hi-Pure continuously, with marked advantages from the clinical as well as the financial viewpoint.

We shall be glad to mail you our new booklet giving clinical details of this gas. Please address 211 Bay Street, San Francisco.

Stuart Hi-Pure Nitrous Oxide

Over 99% Pure

Manufactured only by Stuart Oxygen Co., 211 Bay Street, San Francisco; 2857 Ettie Street, Oakland; 723 East Ninth Street, Los Angeles.

BOARD OF MEDICAL EXAMINERS

(Continued from Text Page 376)

County medical societies would be asked to set up a voluntary health insurance system, providing a list of doctors and hospitals from which members might select and handling the division of fees, without interference from laymen, Mr. Shapiro said." (San Francisco *News*, August 24, 1936.)

In a report on drug addiction in California by the Senate Interim Narcotic Committee, composed of Senators Sanborn, Young and Jack D. Metzger, is published some very interesting information. On page 38 is a commendation of the California State Board of Medical Examiners for its activity in supporting narcotic enforcement, which closes with the following sentence: "No State Bureau is freer from political domination or has a higher ideal of service to the public than the California State Board of Medical Examiners." Commenting on the lack of activity of other State Medical Boards, the statement is made: "In the judgment of your Senate Narcotic Committee, the various State Medical Boards which have failed to act, thus permitting 334 addict doctors to continue to practice (in states other than California) at the expense of the health and lives of their patients, are traitors not only to their state government but the members of their profession, whom they are appointed to represent." Copies of this report may be obtained from the Bureau of Publications, State Capitol, Sacramento.

"The University of California Medical School had a new dean today, Dr. William McKim Marriott, noted pediatrician, recently of St. George Children's Hospital in St. Louis. . . . No changes are contemplated in the administrative policies of the retiring dean, Dr. Langley Porter, said Doctor Marriott." (San Francisco *Call-Bulletin*, July 15, 1936.)

Solicitors on the streets of San Francisco have recently been distributing cards which purport to "type" the individual as to his glandular activity. The cards have been handed to women, with a check mark showing that they have been "typed" by a so-called "endocrinologist" as suffering from hypo- and hyperactivity of certain glands. The recipient of the card is requested to return said card in an accompanying envelope to the "Endocrinology Society of America," Shreve Building, San Francisco, together with 25 cents, and in return would receive a form letter, giving practically no scientific information for the money. The investigation department of the Board of Medical Examiners learned that the "Endocrinology Society of America" was a visionary organization in the form of a trade name; that the idea was suggested by an article printed in the May, 1936, issue of *Esquire*, and a succeeding issue written by George Antheil, about whom appears no information as to scientific training which would warrant the author's acceptance as an authority on endocrinology. The promoters of this Endocrinology Society of America were advised to discontinue their present method of procedure.

"A jury at a coroner's inquest held at the Powell Mortuary this afternoon rendered a verdict to the effect that Hazel C. Scott, forty-two years of age, of 29 North

(Continued on Page 21)

●

VITAMINS IN CANNED FOODS

IV. VITAMIN B_1

● The story of vitamin B_1 is quite long and involved. Properly, it has been fully covered at some length in authoritative dissertations on the vitamins (1).

The original vitamin B of Eijkman and of Funk, while definitely possessed of antineuritic potency, is now known to be of a complex nature. Between 1919 and 1926, the vitamin B complex was resolved into vitamins B (B_1) and G (B_2). Subsequent work has indicated the existence of other vitamins in the complex, whose chemical natures or relations to human nutrition are not as yet clearly understood.

As a direct result of many researches on vitamin concentrates, the chemical identity of the crystalline antineuritic factor has recently been described as a derivative of 6-aminopyrimidine (2).

It has been known for many years that vitamin B_1 may be destroyed by heat. In the canning procedure, a number of heat treatments of food may be involved, especially in the thermal "processing" of the product to insure its preservation. In the "process", many foods are subjected to a heat treatment after sealing in the can, to destroy spoilage organisms which may be present on the raw material. In other cases, the food is filled into the cans at a sufficiently high temperature to obtain the same result. Therefore, the question of the effect of the canning procedures on vitamin B_1 frequently arises.

The times and temperatures necessary for the processing of canned foods are governed by a number of factors, important among them being the pH of the food itself. Highly acid foods require only short heat processes at the temperature of hot or boiling water to destroy spoilage organisms. The so-called "non-acid" or "semi-acid" products require higher temperatures — usually 240° F. (116° C.).

As might be expected, acid foods have been found to suffer only a slight loss of vitamin B during canning (3).

The degree of retention of vitamin B_1 in the non-acid foods is not as high as in the acid foods. (4).

This is partly due to the heat treatments accorded them and possibly also to their low acidity, since the vitamin is more stable in acid media.

The facts in the case may be summarized briefly by the statement that commercially canned foods may be depended upon to supply vitamin B to extents consistent with the amounts of the vitamin originally present in the raw materials from which they were prepared. Because of their widespread use, canned foods contribute a notable amount of vitamin B_1 to the American dietary.

AMERICAN CAN COMPANY

This is the seventeenth in a series of monthly articles, which will summarize, for your convenience, the conclusions about canned foods which authorities in nutritional research have reached. We want to make this series valuable to you, and so we ask your help. Will you tell us on a post card addressed to the American Can Company, New York, N. Y., what phases of canned foods knowledge are of greatest interest to you? Your suggestions will determine the subject matter of future articles.

The Seal of Acceptance denotes that the statements in this advertisement are acceptable to the Council on Foods of the American Medical Association.

Dull the consciousness *of* PHYSICAL DISCOMFORT

SLEEP in the normal healthy person provides an adequate period of physical and mental recuperation. Where normal sleep is disturbed by worry, excitement, pain or physical discomfort, hypnotics or sedatives are often indicated.

Ipral Calcium (calcium ethylisopropylbarbiturate) induces a sound, restful sleep closely resembling the normal. It is readily absorbed and rapidly eliminated. Undesirable cumulative effect may be avoided by proper regulation of the dosage. No untoward organic or systemic effects have been reported in the usual therapeutic dosage.

Ipral Calcium is supplied in 2-gr. tablets for use as a sedative and hypnotic.

Ipral Sodium (sodium ethylisopropylbarbiturate) is supplied in 4-gr. tablets for preanesthetic medication.

When pain accompanies insomnia, Tablets Ipral Aminopyrine (2 gr. Ipral, 2.33 gr. Aminopyrine Squibb) provide both analgesic and sedative effects.

These preparations are available in bottles of 10, 100 and 1000 tablets. For descriptive literature address the Professional Service Department, 745 Fifth Avenue, New York City.

Tujunga Avenue, who passed away last week at the General Hospital, died from septicemia, following an abortion performed by Regina Herschel, 2425 Larissa Drive, Hollywood. The verdict included a recommendation that Mrs. Herschel be held to answer in the case. . . ." (Burbank *Review,* September 2, 1936.)

"Dr. James Beggs, forty-six, was arrested in Oakland yesterday on a telegraphic warrant from Los Angeles on charges of conspiracy in connection with an asserted coast-wide illegal operations ring. Doctor Beggs was one of seventeen persons recently indicted here. He had been scheduled to surrender in court last August 31, when most of the other defendants were arraigned and their trial set for next October 1. Trial of the illegal operations ring suspect was set for October 1 after Deputy District Attorney Vernon Ferguson communicated with San Francisco authorities and learned they had no objection to the Los Angeles trial preceding a similar trial there. Many of the seventeen under indictment here also face charges October 14 in San Francisco." (Los Angeles *Illustrated Daily News,* September 10. 1936.)

"Still another Lindsay case came Judge Piepenburg's way when Paul Doroash, Lindsay chiropractor, charged in Lindsay with violation of the State Chiropractors' Act, pleaded prejudice in the Lindsay court and won a change of venue to Exeter. Doroash was charged by George E. Swanson, a Lindsay man, with having a sign on his office door which might be interpreted as that of a doctor of medicine." (Exeter *Sun,* August 6, 1936.)

"Prosecution of Dr. Malcolm E. Hoffman on a charge of performing an illegal operation ended suddenly at the

Cocomalt
A DELICIOUS FOOD DRINK
CHOCOLATE FLAVOR

IRON · CALCIUM
PHOSPHORUS
VITAMIN D

in this one delicious high caloric food-drink

During convalescence from illness, an operation or childbirth—or when it is advisable to increase the weight of a malnourished child—*there is one food-drink which has proved itself exceptionally useful.*

That food-drink is Cocomalt. Delicious and tempting, easily digested and quickly assimilated—Cocomalt not only adds easily assimilated Iron to the diet, but also richly provides Calcium, Phosphorus and Vitamin D.

An ounce of Cocomalt (which is the amount used to make one cup or glass) supplies 5 milligrams of Iron in easily assimilated form. Thus three cups or glasses of Cocomalt a day supply 15 milligrams—*which is the amount of Iron recognized as the normal daily nutritional requirement.*

Here, then, is one form in which even a capricious child or a finicky adult will take Iron willingly—and at the same time receive other important food essentials. Prepared as directed, Cocomalt adds 70% more food-energy value to a glass of milk.

Vitamin D, Calcium, Phosphorus

Cocomalt is fortified with Vitamin D under license granted by the Wisconsin Alumni Research Foundation. Each ounce of Cocomalt contains not less than 81 U.S.P. Vitamin D units.

Cocomalt also has a rich Calcium and Phosphorous content. Each cup or glass of Cocomalt in milk provides .32 gram of Calcium and .28 gram of Phosphorus. Thus Cocomalt supplies in good biological ratio three food essentials required for proper growth and development of bones and teeth: Calcium, Phosphorus and Vitamin D.

FREE TO DOCTORS:

We will be glad to send a professional sample of Cocomalt to any doctor requesting it. Simply mail this coupon with your name and address.

R. B. Davis Co., Dept. 19-K. Hoboken, N. J.

Your Patients Should Know the Difference!

Last year 20,000,000 Americans took the glare problem in their own hands. With the help of drug store clerks, garage mechanics and road stand vendors, they selected sun glasses intended to relieve their eyes from glare. Because they didn't know the difference, what they actually bought were glasses harmful to their eyes.

Sun glasses are available with two kinds of lenses. Coquille or micoquille lenses (used in the cheap sun glasses) which are unsafe for your eyes, and optically ground and polished lenses (used in the better sun glasses) which are safe for your eyes. Although there is very little apparent difference between these two types of lenses, coquille lenses are usually defective. Proof is the photograph (left) of an image cast by a coquille goggle lens. Defects which cause such distortion in a photograph can cause untold damage to eyes. Compare this with the sharp clear image (right) cast by an optically ground and polished lens. Ground and polished lenses cut down glare without impairing eyesight in any way.

To be sure of safe sun protection, we recommend the prescription of Soft-Lite or Anti-Glare Lenses (neutral glare filters) or auxiliary slip-overs or sun glasses with ground and polished lenses.

Hall of Justice yesterday when the 'star' witness against him proved a bulwark of his defense by giving testimony which brought an immediate dismissal. . . . Alice Rivas, nurse, also was absolved of similar charges." (San Francisco *Chronicle*, August 11, 1936.) "An assault on Margaret E. Hecker, twenty-seven-year-old nurse, last week and subsequent arrest of Dr. Malcolm E. Hoffman was termed 'just a misunderstanding' yesterday by the principals, after admitting they had dined and danced together at a peace parley. . . . Refusing to comment last night, Doctor Hoffman said: 'Yes, it has just been a misunderstanding. Our attorneys are trying to settle the whole thing out of court.'" (San Francisco *Chronicle*, August 15, 1936.)

"Thomas Flint, 33, former CCC doctor in the Redding district, and an unwilling principal in an escape from officers on the Redwood Highway seven months ago, will be taken to San Benito County today. It was understood that he is wanted in the southern county on a narcotics charge. Sheriff Hubler, whose teletype message to Redding resulted in Doctor Flint's arrest, sent word Tuesday that he would arrive early this morning to get the prisoner. After leaving the CCC here, Doctor Flint was arrested in the central part of the State on an Oregon check charge. While he and other prisoners were being transported north by stage, a Negro, to whom Doctor Flint was handcuffed, fled from the officers, compelling the physician to accompany him. The Negro later filed the handcuffs and Doctor Flint returned to surrender to the officers." (Redding *Searchlight*, August 19, 1936.)

"Dr. Louis W. Schreiber, 43, Santa Monica physician of 476 Twentieth Street, was lodged in the city jail Saturday night and charged with drunk driving, following an accident which resulted in serious injuries to Paul Jordan, 1677 Ocean Avenue, police reported. Witnesses said that Doctor Schreiber, driving at an excessive speed, failed to make the boulevard stop at the corner of Twentieth Street and Broadway and as a result crashed into the car driven by Jordan, according to police. Taken to police headquarters, Doctor Schreiber was examined by Dr. Rodney Snow, police surgeon, who reported that the man was under the influence of intoxicating liquor. Bail was set at $1,000. Schreiber was booked on a charge of violating section 501 of the Vehicle Code, a felony. According to police, Doctor Schreiber was committed to the psycopathic ward of the General Hospital for observation last month, following his arrest here on a charge of disturbing the peace." (Santa Monica *Topics*, August 24, 1936.)

"Dr. George E. Watts, who is under indictment at Los Angeles on charges of having performed illegal surgery, yesterday was cited to appear before the State Board of Medical Examiners in Sacramento to show cause why his license should not be revoked. The physician's indictment, the Associated Press reported, followed a state-wide investigation, in which thirty-one persons were indicted in San Francisco and a lesser number at Los Angeles." (Sacramento *Union*, September 6, 1936.)

"The National Association of Chiropodists today elected Dr. G. Earle Whitten of Oakland, California, president." (Associated Press dispatch, dated New York, September 8, printed San Francisco *Chronicle*, September 9, 1936.)

"The declining use of herbs in curing ills is worrying the older Chinese. So worried are they that they called a conference. To the accompaniment of fireworks barrage they discussed ways of inducing youthful Chinese to

use the time-honored herb doctor's prescriptions. Several hundred Chinese, who met with Wong Goon Dick and L. T. Foon of the Chinese Consul General's office, agreed that modern medicine was all right, but they insisted that herbs would cure just as well." (Associated Press dispatch, dated San Francisco, August 17, printed Long Beach *Press-Telegram,* August 17, 1936.)

"The good men do lives after them," said the poet, but it won Dr. S. N. Chernyh probation on a narcotics charge. Tirelessly, Doctor Chernyh, as army physician, had administered to a battalion of the Russian White Army stricken with typhoid. Despite zero weather and lack of medical supplies, he worked night and day, and now 64, he had been arrested for selling narcotics here, but to his aid came survivors of the typhoid epidemic of the White Army. They told of his unselfish work, his kindness, how he could not bear to see anyone suffer, so Federal Judge Michael Roche placed him on three years' probation." (San Francisco *News,* August 24, 1936.)

"Dr. Clair Wilson today lost a $20,500 judgment when the District Court of Appeal reversed an order of the Superior Court for that amount. Doctor Wilson sued his former friend, Dr. George Anthony Zorb, for $255,000 damages as the result of an accidental shooting. Doctor Wilson was wounded by a pistol held by Doctor Zorb February 26, 1933, and he charged that Doctor Zorb had been negligent and careless in handling the weapon, although no criminal intent was alleged. . . ." Los Angeles *Herald-Express,* July 17, 1936.) (Previous entry, April, 1933, and July, 1934.)

"Pleading guilty to a charge of practicing medicine without a license, Grover C. Talbott, chiropractor of 14 East San Fernando Street, was fined $500 by Justice Grandin H. Miller yesterday. Talbott had pleaded not guilty to the charge and his trial scheduled for 10 o'clock yesterday morning, but withdrew his plea of not guilty and pleaded guilty when he appeared before Judge Miller with his attorney, Duncan Oneal. Talbott was arrested by Harry G. Henderson, special agent of the State Board of Medical Examiners, and Deputy Constable Tony Nave on June 1 on complaint of Mrs. Rose Torreto, 391 East Empire Street. . . ." (San Jose *Mercury-Herald,* July 16, 1936.)

"A plea of guilty to a charge of illegal sale of narcotics made yesterday by Dr. Harvey Johnson (James Harvey Johnston), 64, was refused by Municipal Judge Frank Dunn. On account of the seriousness of the charge and

Why MEAD JOHNSON & COMPANY COOPERATES WITH THE COUNCIL

VOLUNTARILY, we market only Council-Accepted products because we have faith in the principles for which the Council on Pharmacy and Chemistry (and the Council on Foods) stand.

We have witnessed the three decades during which the Council has brought order out of chaos in the pharmaceutical field. For over thirty years it has stood—alone and unafraid—between the medical profession and unprincipled makers of proprietary preparations.

The Council verifies the composition and analysis of products, and substantiates the claims of manufacturers. By standardizing nomenclature and disapproving therapeutically suggestive trade names, it discourages shotgun therapy and self-medication. It is the only body representing the medical profession that checks inaccurate and unwarranted claims on circulars and advertising as well as on packages and labels.

The Council, through N. N. R. and in other ways, augments the work of the U. S. Pharmacopoeia, testing and evaluating scores of new products which appear during the 10-year interim between Pharmacopoeial revisions.

We are conscious of the fact that the Council has at times been criticized both in and out of the medical profession. We hold no brief for perfection in any human agency. But we subscribe to the fact that the work of the Council is sound in principle; and in this high-pressure day and age, we shudder to think of a return to the unrestrained patent-medicine-quack-nostrum conditions of three decades ago, when there was chaos instead of Council.

MEAD PRODUCTS, COUNCIL-ON-PHARMACY ACCEPTED:

BOARD OF MEDICAL EXAMINERS

(Continued from Page 23)

because Doctor Johnson was not represented by counsel, Judge Dunn postponed the case until Wednesday. Doctor Johnson was arrested by State Narcotic Inspector Clyde Carpenter. The agent said that after repeated warnings he had sent an under-cover operator to Doctor Johnson's office at 988 Market Street. The man had purchased twenty one-quarter-grain tablets of morphin, which cost the doctor 35 cents, for $10, said Carpenter." (San Francisco *Examiner,* July 21, 1936.)

"Dr. Samuel Twain, 35, physician with offices at 1799 University Avenue, was sentenced to pay a fine of $500 or spend 250 days in jail today by Police Judge Oliver Youngs, after a jury found him guilty last Saturday on ten counts of failing to keep records of narcotic prescriptions issued by him for the prescribed two-year period. Twain indicated that he would pay the fine in $25 installments each month, which Judge Youngs said would be satisfactory. Doctor Twain was arrested last December and acquitted in the court of Superior Judge Frank M. Ogden of Oakland of two additional charges of violation of the state narcotics law. He had been accused of using the names of fictitious patients." (Oakland *Tribune,* July 16, 1933.)

"Denying that he performed an illegal operation on a girl in 1934 (1936), Dr. William B. MacCracken, Berkeley physician and surgeon, today sought a writ of review in the Superior Court on the action of the State Medical Board in revoking his license to practice. . . . On July 8, 1934 (1936), the accusation charging that Doctor MacCracken performed the operation was filed with the State Medical Board by Harry G. Henderson and Officer Ralph Pidgeon of the Berkeley police. On July 13, 1936, the examiners revoked Doctor MacCracken's license to practice." (Press dispatch dated San Francisco, July 17, 1936, printed Oakland *Tribune,* July 17, 1936.)

"The San Francisco police gave aid to San Diego authorities yesterday in the questioning of two women arrested in the southern city on charges of performing illegal operations. Deputy District Attorney John McMahon of San Francisco and a police inspector assisted District Attorney Thomas Whalen in his investigation, according to the Associated Press, after Mrs. Laura Miner, 37, and Mrs. Nedra Cordon, 27, were taken into custody. Bail for the two, first set at $5,000, was reduced to $500, with the consent of Whalen, 'in view of their coöperation.' Preliminary hearing on charges was set for August 3." (San Francisco *Examiner,* July 19, 1936.)

"Action against alleged members of a coast-wide illegal operation ring moved forward in San Francisco and San Diego yesterday. At San Diego dispatches said the statewide probe took a new turn when Attorney Edgar B. Hervey, counsel for two women, jailed after a spectacular raid, declared that his clients were blackmail victims of the coast ring. Hervey was quoted as saying the ringleaders 'horned in' on the San Diego field by shadowing those involved, securing information about their activities and then threatening them with exposure, prosecution and prison unless they agreed to use the syndicate's name and pay $1,000 a month. . . ." Rates, Information and Booklet on Request

Medical Quacks Leave Trail of Woe Behind.—Investigations into the activities of a ring of medical quacks operating in California reveal that a Sacramento family was bilked out of $10,000 for alleged expert eye treatment. The tribute exacted by this gang of "con" men will reach $100,000 in the State, it is believed.

That such swindles could be perpetrated in this enlightened age seems almost unbelievable, but the medical quacks are clever—they have to be. Their stock in trade consists of big words and bigger promises. They flourish because of the laity's awe of medical science and because they have a glib line of sales talk. They do not often make a strike, but when they do they make it count.

Medical ethics exists for the purpose of preventing such tragedies as this. Ethical physicians and surgeons do not go about drumming up practice. Yet in spite of the best efforts of state boards and professional associations to safeguard the public through standardized methods of practice, a quack will occasionally break through the lines and take a patient for his bankroll. Often these quacks have no medical training whatsoever. In some instances they are doctors who have been blacklisted by the profession.

The only safe rule is to call in the doctor you know, the doctor who has an unblemished reputation in the community. Beware of traveling bands of alleged healers who claim to have something the ethical practitioners lack. The quacks are after nothing but the patient's money, and they will get that sooner or later.—*Sacramento Union.*

The key to the world of the future and to the wise fraternity of all races lies in the liberation of the child from the bondage of others' error and sin; from disease and debility, from desertion and want, from ignorance and passion above all, that are visited on the helpless to the third and fourth generation. The heart of a child is friendly to all; like the baby of Della Robbia its limbs are bound, but its arms go out to its fellows. Its single claim is to be allowed to love; its one revenge to die if, for an hour, we neglect it.—Romain Rolland.

ARE
NEW DEPARTURES
ALWAYS
AN IMPROVEMENT
?

NEW methods of manufacture are of interest only insofar as they bring about improvements in the product.

Philip Morris made such a departure by the use of diethylene glycol in place of glycerine, but Philip Morris has proved* that this is a constructive improvement in cigarette manufacture—by producing a cigarette definitely less irritating.

In Philip Morris cigarettes only diethylene glycol is used as the hygroscopic agent.

APPROVED CLINICAL PATHOLOGISTS

American Medical Association Essentials for An Approved Clinical Pathologist

An approved clinical pathologist should be a licensed graduate of medicine. He shall have specialized in clinical pathology, bacteriology, pathology, chemistry, and other allied subjects for at least three years, and he should be reasonably familiar with the manifestations of disease in the body. The director of a clinical laboratory shall be on full time or have definite hours of attendance, devoting the major part of his time to this specialty. A clinical laboratory is an institution organized for the practical application of the fundamental sciences by the use of specialized apparatus, equipment and methods, for the purpose of ascertaining the presence, nature, source, and progress of disease in the human body.

The following Clinical Pathologists directing private laboratories in California are approved by the Council on Medical Education and Hospitals of the American Medical Association:

Clinical Laboratory of Drs. W. V. Brem, A. H. Zeiler, Roy W. Hammack and G. D. Maner, 657 So. Westlake Avenue, Los Angeles, California.

Zera E. Bolin, M. D., 490 Post Street, San Francisco, California.

These laboratories use standard methods and are fully equipped to make all clinical examinations of recognized value in: Tissue Pathology, Bacteriology, Hematology, Serology, Bio-Chemistry, Kolmer Wassermanns, Kahn test, Medico-legal, Basal metabolism, Blood chemistry, Hormone Test for Pregnancy, Parasitology, Cardiology, Autogenous vaccines, etc.

FORM OF CLAUSE OF WILL PROVIDING FOR DEVISE OF REAL PROPERTY

I give and devise unto Trustees Of The California Medical Association, a nonprofit corporation of California, to aid and further its scientific, educational and hospital purposes, and to be known as the ——— Gift, the following described real property situate in the County of ———, State of California, and more particularly described as follows, to wit:

* * *

FORM OF CLAUSE OF WILL PROVIDING FOR DEVISE OF REAL PROPERTY

I give and devise unto Trustees Of The California Medical Association, a nonprofit corporation of California [here describe the property], the same, or the proceeds thereof, to be held as a perpetual fund, to be known as the [here insert name desired] Fund, the income whereof shall be used for and applied to the support and maintenance of scientific, educational or hospital purposes. The said corporation shall have the power to sell said property and to invest and reinvest the proceeds arising from the sale thereof from time to time as it may deem advisable for the purpose of producing as large an income as may be compatible with safety.

Federal Food and Drug Administration Reports.—Violations involving health must come first, but, whenever they can spare time, inspectors give attention to economic frauds. In May there were seizures of the following commodities in this class of violations: 640 cans of apricot juice and 620 cases of tomato juice, both containing added water; 1,300 cans of so-called olive oil consisting mostly of tea seed oil, and 213 bottles of short-volume olive oil; 3,036 packages of a so-called "Old English" cheese owing its advertised "tingle" to a liberal sprinkling of red pepper rather than to its age and to the curing process, as claimed in its labeling; 120 jars of preserves deficient in fruit, 370 cases of substandard canned peas not labeled to show their substandard condition, and 658 cases of canned pears showing a like violation.

There was only one seizure in May on a charge of the presence of a poisonous ingredient. It involved a shipment of wine found to contain dangerous quantities of fluorine. Sixty-six bottles were seized and destroyed. A hundred cases of beer and ale were also seized because of label representations of alcohol contents ranging from 8 per cent to 14 per cent, when the beverages contained in fact only between 4.6 per cent and 6.5 per cent of alcohol.

Drugs seized in May included one lot of below-standard epinephrine ampoules, 93 cans of deteriorated ether, 38 bottles of below-standard chloroform, 1,300 bottles of so-called rubbing "alcohol" made up mostly of isopropyl alcohol, and the following products seized because of false and fraudulent medicinal claims: "Chlor-O-Zone," a water solution of chloramine, for pyorrhea, bleeding gums, infected wounds, trench mouth, stomatitis, tonsillitis, dermatitis, vaginitis, conjunctivitis, leucorrhea, sore throat, pink eye and eczema; "Kadiok," consisting of water and 7½ per cent alcohol (the label claimed 15 per cent), offered for ailments of the digestive tract, rheumatism, high blood pressure, appendicitis, kidney and liver disorders, backache, nervous disorders and sleeplessness; "L.H.C. Herbal Compound," a water-and-alcohol solution of plant extractives including laxatives and alkaloids, with iron compounds and salicylates, falsely represented as containing potassium and iron iodides, iron peptonate and sodium salicylate, for eruptions, pimples, tetter, acne, rash, rheumatism, arthritis, lumbago, sciatica, scrofula, boils, impure blood, septicemia, chronic constipation and anemia; "LaGreen's Famous Healing Oil," represented as a rattlesnake oil but consisting of kerosene, mustard oil and sassafras oil, for rheumatism, aches, pains, soreness, stiff joints, colds,

headaches, toothache, croup and pneumonia; "Life-Aid Mineral Compound," consisting of sodium, magnesium and calcium sulphates, sulfuric acid and sugar, and small amounts of salicylic acid, iron phosphate and saccharin in water with a red dye, for indigestion, gastritis, rheumatic pains, nervousness and dull, weak feelings; an extract of witch-hazel offered for the treatment of painful swellings, lame back, piles, sore throat, and rheumatism; and a mouth wash claiming to be "highly antiseptic" and a "powerful germ-killer," but shown on test to be ineffective against the ordinary pus-forming organisms.

How to Keep the Baby Well.—Most babies are well when they are born. To keep your baby well feed him according to the doctor's advice, teach him good health habits, and get the doctor's help in guarding him against disease.

A well baby has clear skin, bright, wide-open eyes, springy muscles, and a contented expression. He cries very little, has a good appetite, sleeps quietly with his mouth closed, and has regular bowel movements of the normal color and consistency. He shows no evidence of pain or discomfort, and he gains steadily in weight, height, and ability to do things.

As a rule the baby doubles his birth weight by the end of the fifth or sixth month and trebles it by the end of the first year. During the third month he learns to hold up his head when his body is supported. From the third to the fifth month he usually begins to laugh aloud. At seven or eight months he may sit erect and soon will be beginning to creep. He begins to walk at 12 to 18 months. At one year of age he usually can speak a few words. Usually his first teeth appear when he is six or eight months old. At one year he probably will have six teeth, at one and one-half years, twelve; and at two years, sixteen.

If your baby does not have these signs of health and normal development, tell the doctor.

Do not wait to consult the doctor until something goes wrong, however. You should keep your baby under the doctor's supervision from birth. A mother cannot recognize many early signs of trouble, for she is not trained to do this. Perhaps she is too near the baby and sees him too often to realize that any change is taking place. The doctor, who sees the baby once or twice a month, looks at him with a trained eye and can see whether he is as rosy as usual or is getting a little pale, whether he is as active as he should be, or whether he shows other signs that may mean trouble later.

Weigh the baby once a week, at home or at the doctor's office or at a child-health center. At least once a month mother and baby should be seen by the doctor for general advice.—*The Children's Bureau, United States Department of Labor, Washington.*

Feeding the Baby.—As soon as the baby is born consult the doctor with regard to feeding, and follow his advice with care.

The best food for the baby in his first six or seven months is his mother's milk, but whether the baby's mother nurses him or whether he is artificially fed, he soon needs additional foods besides milk. The artificially fed baby especially needs such foods.

Before the end of the first month the baby should begin to have cod-liver oil or other source of vitamin D. If you give him cod-liver oil be sure that it has been tested for vitamin D. It is better to begin giving cod-liver oil at the end of the baby's second week, especially if the baby is artificially fed. Except in very warm, sunny climates both cod-liver oil and sunlight are needed if the baby is to be protected from rickets.

Orange juice or tomato juice should be given to prevent scurvy. It should be given to every baby by the end of the first month. If the baby is artificially fed, it should be begun earlier—at the end of the second week.

Cooked cereal may be begun at the beginning of the fifth month. Egg yolk is usually begun by the fifth month.

(Continued in Back Advertising Section, Page 34)

What makes a bio-assay dependable?

For dependable bio-assaying of a vitamin product, special and elaborate facilities are necessary. Variables must be eliminated wherever possible. The scientific staff must possess a degree of ability which can be gained only by long and thorough experience.

Considering the complexity of the bio-assay and the known fact that deficient vitamin products are offered for sale, many thoughtful physicians take definite steps to protect their patients. An effective way is to *write* all prescriptions for Haliver Oil with Viosterol and to specify *Abbott* whenever Vitamins A and D are indicated.

This original research product is rigidly bio-assayed in a modern laboratory complete in every detail, even to being air-conditioned. The laboratory is large and fully adequate for the extensive demands placed upon it. All test animals are bred and raised within the laboratory—thus removing chance for error non-uniform animals would cause. The assays are conducted by a scientific staff which is long and thoroughly experienced in this exacting work.

Prescribe Abbott's Haliver Oil with Viosterol routinely for pregnant and lactating mothers, for growing children, and for all other patients who require a rich source of Vitamins A and D. Available in soft, tasteless 3-minim capsules in boxes of 25, 50, 100 and 250. Also in 10-cc. and 50-cc. vials.

A NEW LEGISLATIVE PROBLEM: POSSIBLE DANGER TO CALIFORNIA STATE MEDICAL PRACTICE ACT

California's Medical Law of 1876.—California's first Medical Practice Act came into existence on April 17, 1876, at an annual meeting of the Medical Society of the State of California, the State Legislature having, on April 3, 1876, enacted a law

> providing for the appointment of medical examiners, who should be authorized to determine, in accordance with the provisions of the aforesaid enactment, what persons are duly qualified as practitioners of medicine and surgery.

In the two years which followed, a total of 1,026 regular physicians were duly licensed, and of these some 1,015 physicians became members of the Medical Society of the State of California.

* * *

Amended Laws of 1878: Three Examining Boards.—Grave doubts having arisen concerning the adequacy of the law of 1876, the Medical Society of the State of California (by which name the California Medical Association was formerly known) proposed to the Legislature certain amendments, and these having been enacted, became law on April 1, 1878. The Board of Examiners so created were representatives of the

> Medical Society of the State of California, the Eclectic Medical Society of the State of California, and the California State Homeopathic Medical Society, corporations organized and existing under and by virtue of the laws of this State, and no other corporation, society, persons or person, shall appoint annually a Board of Examiners, consisting of seven members, who shall hold their office for one year, and until their successors shall be chosen.

Concerning that law the Supreme Court of the State of California, considering an appeal attacking the statute, stated as part of the opinion then handed down:

> Our conclusion is that, by conferring the authority and imposing the duty of appointing boards of examiners on the three societies named in the Act, the Legislature did not exceed the limitation of its powers contained in the provision of the Constitution above quoted; and that it is unnecessary herein to express any opinion as to the power of the Legislature to require that the fees collected by the boards should be paid to the societies named, since—even if it be assumed that such portions of the law are unconstitutional—the remaining portions are stated independ-

† Editorials on subjects of scientific and clinical interest, contributed by members of the California Medical Association, are printed in the Editorial Comment column, which follows.

> ently, and of themselves contain a complete scheme for the examination of diplomas and applicants, for the prohibition of certificates by others than those empowered by the Act to issue them, and for the punishment of charlatanry and empiricism.

* * *

Amended Law of 1907: A Newly Created Composite Board.—Without delving further into a detailed history of the Medical Practice Act, it may be in order to mention several important changes. By 1901 the Legislature of California had created a Board of Osteopathic Examiners, but on May 1, 1907, a law was enacted which

> repealed the prior medical and osteopathic acts and provided for the appointment of a composite board to regulate applicants from all schools and the practice of those licensed. This Act contained the following provisions: (1) Board made up as follows: Five members of Medical Society of State of California, two members of California Homeopathic Society, two members of Eclectic Medical Society, two members of Osteopathic Society of State of California.

* * *

The 1922 Initiative Laws of the Sectarian Schools.—The above arrangement continued until 1922, when, at the general election of November 7, 1922, the citizens of California, by initiative vote, created a separate Board of Osteopathic Examiners, that initiative law containing provisions making it possible to secure certain changes by amendments to the Medical Practice Act.*

* * *

Existing Medical Practice Act Somewhat Loose in Phraseology.—An inspection or perusal of the existing Medical Practice Act of California immediately gives the impression of a seeming lack of proper order and clarity of expression; on which account the suggestion has been rather frequently made that it would be a more readable document if it were rearranged or codified. In that point of view, members of the present and previous Boards of Examiners have concurred. However, with a greater understanding of the difficulties encountered by them in carrying out the law's provisions, and the knowledge that some of the strongest and most needed portions had received the sanction of the State's Supreme Court, they have been reluctant to propose amendments incorporating changes in phraseology or text which, being new, might again need court opinions to establish their constitutionality or scope. That is why, in the last ten to twenty years, amendments proposed by the Board have been of a constructive rather than radical nature; such as were proposed being advocated only when experience in board procedures indicated their special need.

* * *

A New and Serious Complication.—Comes now, out of a comparatively clear sky, a duly and legally constituted State body, the California Code Commission, created by the provisions of a legislative enactment known as Chapter 750, Statutes of 1929, to

> undertake a restatement of all the statutory laws [of the State of California] "as will best serve clearly and correctly to express the existing provisions of the law." (Stats. 1929, Ch. 750, p. 1427, as amended.) In doing this work the Commission seeks to codify the statutes, without any change in the effect that they now have in their uncodified condition. No substantive change in the law is to be made.

Among the laws naturally considered by the California Code Commission is the Medical Practice Act, which, through the Commission's statute advisers, has been practically redrawn, a final redraft to be prepared and introduced to the Legislature which will convene in January, 1937; such codified form of the present Medical Practice Act to be submitted with a recommendation for passage without amendment.

In other words, the present Medical Practice Act, as finally codified by the Commission (but without the addition of any new provisions), will be sent to the Legislature, with other laws of California, and will probably be passed without alteration. Wherefore, of course, it is necessary that the codified draft, when submitted, in all essential provisions should be the same as the present Medical Practice Act and be acceptable to the medical profession.

* * *

First Draft of the Codified Medical Practice Act Is Now Being Considered.—This first draft of the codified Act has been mimeographed and sent to members of the profession who have been recommended to the Commission as persons able to be of advisory service. That the matter is of no trivial importance may be noted in perusing the letter sent by Dr. Charles B. Pinkham, Secretary of the Board of Medical Examiners of the State of California, to Mr. Arthur McHenry, Statute Reviser, whose name is signed to the transmittal letter accompanying the mimeographed redraft. Because of the great importance of the Medical Practice Act to every legally licensed physician in the State, this letter of Doctor Pinkham is here reprinted in full:

San Francisco, California,
September 14, 1936.

Subject:

Yours of September 10 re Medical Practice Act—Revision.

California Code Commission,
Sacramento, California.

Attention, Mr. Arthur McHenry, Statute Reviser.

Dear Mr. McHenry:

This will acknowledge receipt of your letter, stating that Lester R. Daniels, D. O., Secretary of the Board of Osteopathic Examiners, together with John L. Brannely, attorney for said Board, have requested an interview relative to the revised Medical Practice Act, as mimeographed in the "Proposed Business and Professional Code."

The undersigned must state that he is very much concerned over the way in which the Medical Practice Act has been torn apart, as manifested by the mimeographed copy recently received from you. Inasmuch as the entire medical profession of this State (as well as the osteopathic profession) is interested in the Medical Practice Act, a conference such as you mention should be open to the Council of the California Medical Association: June Harris, M. D., Medico-Dental Building, Sacramento, Chairman of the Legislative Committee of the California Medical Association; Charles E. Schoff, M. D., Chairman of the Committee on Legislation of the Board of Medical Examiners; Hartley Peart, Attorney-at-Law, and Counsel for the California Medical Association; Fred C. Warnshuis, M. D., Secretary of the California Medical Association; the deans of the Medical Schools of California, etc.

---

* See August, 1936, issue of CALIFORNIA AND WESTERN MEDICINE, page 117, for comments on this provision of the law.

My reading of the mimeographed revision of the Medical Practice Act, recently received from the California Code Commission, impresses me with the idea that the existing Act has been thoroughly riddled. In my opinion the revision of said Act so confuses the present Act that it gives promise to open the gates for a lowered standard of education and licensure, as well as to embarrass the enforcement of the law.

The present Medical Practice Act is the result of careful study by some of the best legal minds, both in the Legislature and outside. Many sections have been written by men who are now Superior Judges. Amendments have been numerous, that defects discovered through experience with its workings might be remedied. The Act in its many provisions has been thoroughly threshed out in the various courts. Its constitutionality has been determined by the United States Supreme Court. To throw aside all the years of strenuous endeavor and start with a new-born infant seems futile.

Such an important law as the present Medical Practice Act should not be dissected and rearranged into the confusing form recently sent out by the Code Commission. The revision proposed by the Code Commission will necessitate a readjudication of many of the salient features of the Medical Act.

I am sending a copy of this communication to the Secretary of the California Medical Association and its Chairman on Legislation, as well as to the deans of the various medical schools in this State, all vitally interested in maintaining the standards of the California Medical Practice Act.

Very truly yours,
C. B. Pinkham, M. D.,
Secretary-Treasurer.

* * *

The Redraft of the Present Medical Practice Act Is the Profession's Major Problem No. 1 in the 1937 Legislature.—It may be stated that, in the above recodification, we have Major Proposition No. 1 needing very prompt and explicit attention, not only by the Board of Medical Examiners, but by every officer and member of the California Medical Association and its component county societies.

The Council of the Association, which meets in Los Angeles on September 26, will no doubt give the matter its most careful consideration and take all necessary action to keep component county societies and members informed concerning this new issue.* The subject, it need hardly be said, is of tremendous importance; because, if the codification of the Commission shall be found to be lacking in the soundness of the present Medical Practice Act, it may permit the legal recognition of hundreds of practitioners not now eligible to practice as physicians and surgeons in California to, after all, secure licenses. Such a calamity would be a real blow both to public health and also the best interests of medical practice. The importance, therefore, of active interest in this matter by every physician already licensed to practice here cannot be overemphasized, and members of the California Medical Association are urged to keep in close touch with the situation as it develops.

AUTOMOBILE ACCIDENTS AND "VEHICIDES": SOME FEDERAL AND CALIFORNIA STATISTICS

One of the Leading Causes of Death.—In recent years it has become necessary to include among the leading causes of deaths of human beings the constantly-increasing automobile accidents, and this in spite of organized effort in many parts of the United States through laws and publicity campaigns to bring about a saner use of serviceable, but also dangerous, auto vehicles.

As a consequence of which physicians, who year after year read article after article in the medical press, dealing with improved methods of treatment through which it is hoped that occasionally an extra life might be saved, may well wonder at the seeming indifference by so many persons driving automobiles, to the health and lives of their human fellows.

* * *

The Appalling Federal Figures.—Consider for a moment that in the year 1935 the United States showed a total of 1,285,000 injuries, and 37,000 deaths due to motor accidents. Also, that 105,000 of the nonfatal injuries resulted in permanent disabilities. These summaries are certainly little less than appalling!

* * *

California's Unenviable Record.*—To bring the statistics nearer home, meditate on the mortality from automobile accidents as publicized by the United States Bureau of the Census:

Of the fatal mishaps due to automobiles for the brief four weeks' period ending August 29, 1936, Long Beach had 6 resulting in death; Los Angeles, 36; and both San Diego and San Francisco, 7. For the same period, New York City had 20 deaths; Chicago, 59; and Philadelphia, 20.

For the entire year, ending August 29, 1936, vehicide deaths were:

Los Angeles, 549; Long Beach, 59; San Diego, 58; San Francisco, 56, when, by contrast, New York had 949 deaths; Chicago, 743; and Philadelphia, 254.

While the death rates from automobile accidents per 100,000 population for the same fifty-two weeks were as follows:

Los Angeles, 37.5; Long Beach, 35; San Diego, 34.3; San Francisco, 8.3; New York, 13; Chicago, 19.4; and Philadelphia, 12.8.

* * *

Where Are We Lacking?—Vital statistics such as the above cannot do otherwise than excite both wonderment and sorrow. Somewhere, something is wrong, something lacking. One thing is certain: too many persons drive automobiles who should not be permitted to do so—drunken persons, children, mentally and physically deficient individuals. Adequate automobile licensure laws, also, are evidently lacking. Likewise, the penalizing statutes for improper driving and, perhaps, more than that, the weakness of certain police and court jurisdictions in handling automobile accident cases.*

---

* The California Medical Association Council on September 26 appointed a special committee of five, with Dr. Morton R. Gibbons as chairman, to act on this matter. The committee will be glad to receive suggestions.

* See also current news items on page 372.

In California, San Francisco is to be congratulated on its low death rate of 8.3, in contrast to that of Los Angeles, with 37.5; Long Beach, with 35; and San Diego, 34.3. San Francisco must have something more than its hills (deterrents to reckless drivers because of the primary danger to themselves) to account for its favorable record. In addition, New York, Chicago, and Philadelphia, each presents a rate that justifies self-analysis by the citizens of Los Angeles, Long Beach, and San Diego.

* * *

Have County Medical Societies No Obligation in This?—When will this mutilation and death of human beings, so possibly preventable, be lessened? Is it not within the province of medical men and women, who spend so much of their efforts in preventive medicine along other lines, to take a more active and organized part in betterment efforts toward this grave problem? Would it not be a proper expression of coöperation if every county medical society in the State of California appointed a special committee to work with other civic groups in promoting measures to lessen the number of vehicides in the State of California?

FALL PROGRAM TIME FOR COUNTY SOCIETIES

The Summer Vacation Months Are Behind Us: What Now?—Once again, at the end of the summer vacation months, we take up our county society meetings. How will those of the fall months measure up to those of the winter and spring of the current and previous years? How can interest in the meetings be stimulated, and what means have we at our disposal whereby they may be made still more valuable? What are some of the basic things to keep in mind concerning meetings, and what organization and other problems should receive special attention in the months immediately ahead? These and similar questions come to the minds of alert officers and program committees; the difficulty, however, is not to have perplexing questions such as the above bob up for consideration, but to find the solutions best adapted, in each instance, to local needs and desires.

* * *

The Societies in the Metropolitan Centers.—County societies located in metropolitan centers naturally have problems quite different from those met with in counties of much lesser population. The larger a society becomes, the less interest do its members display in meetings of the entire unit, and the more do they give their efforts to sections in the specialties. In several respects this is unfortunate; and yet, because of the professional, family, social and other demands on time, and also because of geographical factors, it is not easy for many members to devote even one evening a month for a general county society meeting. For if the papers presented prove of little interest, and if there be no social or fraternal contacts before or after the program, the attending member, after a few such experiences, is apt to decide that he will derive more pleasure and profit by remaining at home with his family, quietly reading the literature always awaiting his attention.

* * *

The Experience of the Los Angeles County Medical Association.—It has been interesting to watch the trends in meeting attendance in the Los Angeles County Medical Association. About twenty-five years ago that society, with a membership of about eight hundred, and only one or two sections in the specialties, had rather large general meetings. But—and the "but" is important—in those days, at the end of every meeting and at the expense of the Society, a generous buffet luncheon was served, members remaining oftentimes almost one hour after the closing program hour of ten. Yet it may be taken for granted that the type of scientific paper presented then was of much the same order as those of today. What, therefore, was the general meeting lure of those days? Among those who attended it is agreed that it was the good fellowship, promoting the formation of new friendships and better understandings, associated with chattings over the coffee, that led several hundred men to come out once or twice a month; whereas now, with a membership of more than two thousand, a considerable lesser attendance is in evidence at the general meetings.

It must be noted that this is not stated in criticism of the present-day organization of that society, which has not only a total of twelve geographical branches, but an additional fourteen sections in the specialties, some with as large, or larger, attendance at their monthly meetings than is to be seen at the general meetings. The reasons are easily understood: physicians are primarily interested in their special work and their local communities, and they naturally find it more easy and profitable to participate in the programs of a specialty section or a geographical branch.

With the highly differentiated set-up in the large Los Angeles County Medical Association of today, in a county covering a geographical domain as large as a New England state, it is not to be wondered at that the old order has passed. The present task in that society is to have every geographical branch and specialty section avail itself of all its opportunities and to make the respective work of each of most value to its members; while at the same, and at all times, integrating their members into the policies and aims of the general organization.

---

* An article in the *Readers Digest* of October, 1936, on "Foolproof Roads," condensed from *Fortune*, contained the following paragraph:

Careful estimates indicate that 15 per cent of the drivers cause nearly 100 per cent of the accidents. Among them are the speed maniacs, the wilfully reckless drivers, the habitually drunken drivers, the psychopaths, the physical defectives, the juvenile irresponsibles, and the automotive morons. The only effective way to handle such menaces is to police them off the highways, and here the states have failed almost completely. Four states impose no restrictions whatever upon the driver. Eight others require only that noncommercial operators shall have attained a certain age, as low as fourteen. Of the remaining thirty-six that make drivers procure licenses, twelve grant them on mere application, and of the twenty-four states that demand driving tests not one imposes a sense-making examination.

* * *

Wherein Nonmetropolitan Societies Are Fortunate.—The members of nonmetropolitan societies may congratulate themselves upon their good fortune in being able to know one another with considerable intimacy and, through their organization, to derive not only pleasure from the meetings, but profit in a considerable degree from association with one another, as they daily go about in the practice of their profession. It is gratifying to note that most of the smaller county medical societies appreciate the possible benefit through a preliminary dinner, or a postmeeting supper, as part of the regular procedure. The value of such social sessions, indeed, cannot be overestimated. We cannot break bread with and also dislike or hate one another.

* * *

Concerning Scientific Programs.—A few comments concerning the scientific papers. The program committee (of whoever it may be composed: the secretary, the president, or a special group) should map out, if possible, its program in advance. Such a plan is satisfactorily carried through in many societies, and with some effort it can be made practical in all organizations. Do not depend altogether on outside speakers. The members of a medical society profit most in proportion as they themselves make an effort to contribute papers on medical problems coming under their immediate observation. This is particularly the case if such presentations are followed by free and kindly discussion participated in by other local colleagues. The out-of-county speaker should be on the occasional, rather than on the regular program.

To stimulate extra interest, clinic days may be arranged, to occur from time to time. The State Association is prepared to aid in this, and the Association Secretary will coöperate in all such endeavors.

* * *

Civic Obligations.—Let it not be forgotten, too, that in November of this year, less than a month away, the State election will be held. At that time the State assemblymen and State senators who make up the legislature will be elected.

The members of every county society should know the attitude on public health and medical practice questions of all such legislative candidates. "An ounce of prevention is worth a pound of cure." Find out what you want to know in advance, not afterward: for no candidates who are opposed to legitimate public health or medical practice standards should be supported by physicians. More than that, every proper and diplomatic method should be used to prevent the election of such candidates.

The 1937 California Legislature will have before it many items of grave importance to medical men and women. One of these, the codified Medical Practice Act, is discussed editorially in this same issue of California and Western Medicine. Officers of county societies who fail to call the attention of their members, before the legislature assembles, to the importance of civic obligations may have reason to reproach themselves after the legislature adjourns!

* * *

To Summarize.—On our immediate needs, which are: stimulating professional programs, best possible set-ups for fraternal and social understandings, and alertness to civic responsibilities in relation to public health and medical practice standards. Those should be some of our major objectives in the present and immediate future.

Other State Association and Component County Society News.—Additional news concerning the activities and work of the California Medical Association and its component county medical societies is printed in this issue, commencing on page 364.

EDITORIAL COMMENT†

THE PULSE PRESSURE—PULSE RATE EXERCISE TOLERANCE TEST

Since 1889 the effects of exercise on the blood pressure and pulse rate have been studied and used as tests of efficiency of the circulatory system. The difficulty in drawing conclusions from various reactions has been that individuals with effort syndrome, but no organic heart disease—the so-called "irritable hearts" and "soldiers' hearts," showed extreme fluctuations of blood pressure and pulse rate. Most tests gave as the normal response a rise of the systolic blood pressure and pulse rate to a given degree, *i. e.*, blood pressure 120 to 140 systolic, and pulse of from 80 to 100 with a fixed exercise. A normal reaction should show a return to previous levels within two and one-half minutes. Often formulae were developed, such as in the Schneider test. T. R. Harrison estimated cardiac efficiency by measuring dyspnea after fixed exercise, developing the formula for a normal ventilation quotient.

Master devised as an exercise tolerance test the ability of the blood pressure and pulse rate to return to within ten points of normal levels within two minutes after cessation of exercise. He wisely presented tables of normal degree of exercise for different ages and weights (Table 1). The figures represent the number of ascents of a 1½-foot, 2-step climb in one and one-half minutes, which, if multiplied by weight, equal foot pounds per minute of work (excluding work of descent). Some

dyspnea results, which represents an oxygen debt. This test alone is of much value, but in recent years the author has used a test of heart function depending on the general assumption that widening-pulse pressure is an index of increased systolic heart output. Starr, Y. Henderson, Bock, Burwell and others have shown that there is a correlation between a rising-pulse pressure and an increased systolic heart output, and Ogden and Shock have worked with normal adolescents (an unfortunately unstable group) in attempting to demonstrate this correlation. Bazett and his collaborators recently have proved this relationship, using a special technique for blood pressure recording.

It is well known that in heart failure the pulse pressure narrows and the pulse rate rises, improvement often being measured by reversal of this state. The logical reason for this is that the minute output of the heart of oxygenated blood for the tissues must be maintained by a rising pulse rate (through the Bainbridge reflex) when the output per beat falls. Exercise to the point of dyspnea puts an increased demand on any heart by producing an oxygen debt. This should roughly tell us whether the muscle is able, through diastolic dilatation and forceful contraction, as represented by the pulse pressure, to proportionately take care of the increased minute output, or if the increased rate must account for most of it. One can combine the Master's test of variable amounts of exercise, using a one-foot step for one minute, with an analysis of the proportion of increase of pulse pressure and pulse rate to tell how the heart is taking care of the minute output demanded. The normal may show figures as follows: Resting blood pressure 120/80 = 40 pulse pressure, 60 pulse rate; after exercise, blood pressure 140/80 = 60 pulse pressure (a 50 per cent increase) and 90 pulse rate (a 50 per cent increase). A patient with myocardial damage, on the contrary, characteristically shows figures such as: Resting blood pressure 120/80 = 40 pulse pressure, 60 pulse rate; after exercise, blood pressure 130/80 = 50 pulse pressure (a 25 per cent increase) and 120 pulse rate (a 100 per cent increase). Such a patient, after his Standard Master's exercise, would not return to a normal condition in blood pressure and pulse rate in from two to two and one-half minutes.

Patients with complete heart-block illustrate this phenomenon particularly well. Since their pulse rate is fixed, their only means of increasing minute cardiac output is by increased systolic output per beat, *i. e.*, resting blood pressure 160/80, pulse rate 40; after exercise, blood pressure 240/80 = 100 per cent increase, pulse rate 40. Occasionally, the duration of systolic output is prolonged, *i. e.*, aortic stenosis, which would destroy the correlation of pulse pressure increase and systolic output increase. Naturally, aortic insufficiency would distort the estimates, and marked arteriosclerosis of the great vessels tend to exaggerate the pulse pressure reactions. In patients with angina pectoris, occasionally the pulse rate does not rise proportionately to pulse pressure. Even in unstable individuals, *i. e.,* adolescents and patients showing effort syndrome, it is rare that a marked disproportion is encountered even though both pulse and blood pressure responses are exaggerated and remain abnormally elevated.

CARDIAC MURMURS

The stethoscope is of little clinical value unless the physician understands the significance of the sounds he hears. When the auscultatory method is properly applied to the circulatory system, the ability to diagnose certain functional disturbances is greatly enhanced, and the nature of lesions predicated. Fortified by this evidence, prognosis and treatment may be more rationally directed.

Cardiac murmurs may arise from several sources; some external to the heart, but all associated in some manner with its contraction. In growing children and young adults, faults in stream-lining of the heart and great vessels are probably responsible for most of the so-called functional murmurs. They are usually systolic in time and localized. Cardiorespiratory murmurs are also common at this age and have no clinical significance. Pericardial or pleuropericardial friction sounds are also differentiated from murmurs of valvular origin.

Murmurs arising in conjunction with valvular defects are important. Their location in the chest, direction of transmission, intensity, pitch and time in the cardiac cycle determine their point of origin. The effects of exercise and change in posture may aid in interpretation.

In studying the propagation of cardiac murmurs, it is well to remember that they travel on or with the blood current in somewhat the same fashion as audible sound travels on the wind. It is easier to whistle down the wind than up the wind.

Variations from the normal cardiac sounds and murmurs in the periphery will be taken up at another time.

Systolic murmurs at the base tend to be rough; if from the aortic valve, to be transmitted upward along the course of the larger branches of the aorta, and if from the pulmonic valve, to be transmitted more readily toward the left clavicle. They are frequently accompanied by a systolic thrill. If the aortic valve is more than slightly stenosed, the pulse is of the plateau type. A subject with a dilated aorta or dilated arteries arising from the arch may present a systolic murmur and thrill over the upper sternum and vessels at the root of the neck. This must be differentiated from aortic stenosis.

Aortic diastolic murmurs are usually soft, tend to replace the second aortic sound and are transmitted toward the apex, often fading over the midcardiac region where the right ventricle overlies the left ventricle, and becoming more audible again at the apex. A mid-diastolic rumble accompanied by a thrill at the apex may be noted in a few cases, and in a considerable number of cases a presystolic murmur (the Austin Flint murmur) and thrill will be observed at the apex. (The driving character of the aortic diastolic murmur is notable.)

Pulmonary diastolic murmurs (Graham Steele type) are usually of brief duration, localized to the second and third left interspaces close to the sternum. They are usually associated with right cardiac failure and are, therefore, generally transient. We have described a new murmur, presystolic in time, heard best at the tricuspid region in pulmonary insufficiency, and probably having the same mechanism as the Austin Flint murmur in aortic insufficiency. This murmur is also heard in right-sided failure and is transient.

Mitral systolic murmurs are heard best at the apex and are transmitted to the left and back. They are high-pitched and blowing in character. The harsh rasping systolic murmur at the apex in cardiosclerosis is most frequently associated with hypertrophy and dilatation of the heart, and sclerosis of the mitral valve. Exercise generally increases the intensity of the murmurs of mitral insufficiency.

Mitral diastolic murmurs may be early, middle, or late (presystolic). The auricular or presystolic murmur disappears with the onset of auricular fibrillation in the absence of aortic insufficiency. In rapid hearts the various phases of the murmur cannot be accurately recognized as the rumbling presystolic crescendo and loud first sound predominate, especially after exercise.

Tricuspid systolic murmurs are almost the rule in congestive heart failure. They are heard best over a small area at the lower sternum, just to the left of the lower sternum or in the epigastrium. They are of brief duration, "close to the ear," and often have an amphoric quality. With organic tricuspid valvulitis the murmur may be very harsh, and accompanied by a thrill.

Tricuspid diastolic murmurs are relatively uncommon and are usually associated with tricuspid stenosis. They may be early or late in diastole (presystolic). The presystolic phase disappears with the onset of auricular fibrillation.

CHRONIC VITAMIN D TOXICITY

A warning against the possibility of acute or chronic poisoning from excessive administration of vitamin D preparations was recently made in these columns.[1] It was pointed out that there is as yet no evidence to indicate what the chronic toxicity of vitamin D preparations may be, especially if contaminated with "toxisterol." This poisonous ingredient, which may be present in any irradiated ergosterol product if the irradiation is not carefully controlled, is a powerful calcifying agent, but has no significant antirachitic properties.[2] Long-continued administration of relatively small amounts of vitamin D preparations, contaminated with "toxisterol," may lead to abnormal calcifications, whose presence may not be suspected for many years. It is doubtful that "calciferol," the most satisfactory irradiated ergosterol, is identical with natural vitamin D.[2] But there is evidence to indicate that excessive administration even of natural vitamin D products (including cod-liver oil) may promote cardiac disturbances or vascular abnormalities.[3]

---

[1] Leake, C. D.: Calif. and West. Med., 44:149 (March), 1936.

Another more serious possibility concerning too extended or intensive use of vitamin D or irradiated ergosterol preparations has arisen as a result of the brilliant chemical work of the past six years on phenanthrene derivatives.[4] The most complex substances in this series are the sterols, which, by progressive dehydrogenation, may be converted into bile acids or sex hormones. The most potent carcinogenic agent known is methylcholanthrene,[4] which can readily be formed from bile acids by reactions of the type known to occur in the body. Fieser conservatively states that "while proof is entirely lacking, it appears possible that many forms of cancer may originate in the metabolic production of methylcholanthrene or related substances from the bile acids, or perhaps from the sterols or sex hormones, of the body."[4]

If such a possibility exists, there is further reason to urge caution in using, or advising for use, indiscriminate amounts of vitamin D or irradiated ergosterol products in excess of what the body needs, or can synthesize itself if there is sunlight available. It is important to remember that the experiment has not yet been made. We do not know whether or not the spontaneous cancer incidence in mammals given large amounts of vitamin D in infancy and adolescence would be any greater than in a series not so treated. But in humans it is wise, if the possibility exists, not to take the chance.

Naturally this is not an argument for interfering with the effective treatment or prevention of rickets by vitamin D. But it is a plea to use some discretion in the amounts of vitamin D prescribed. Commercial enterprise is endeavoring to capitalize to the fullest in the current popular vogue for vitamin D. In addition to a sun-tan craze, there are ballyhooed everywhere irradiated foodstuffs of all varieties, metabolized milks, and even "sunshine soaps." It is ridiculous. But when, on top of an unknown but probably quite adequate intake of vitamin D, especially in sunny California, children are dosed with large amounts of vitamin D preparations by overanxious mothers, it is time for physicians to use care in prescribing the drug. As in every phase of chemical use in medicine, physicians should carefully weigh the risk of using the chemical against the hazard of the disease. And the public should realize that vitamin D is a drug, that its administration should be guided by a physician, even in connection with metabolized or irradiated milk, and that commercial efforts to promote its indiscriminate use are ballyhoo for gain without due regard for public welfare.

Concerning this matter the Director of Public Health of San Francisco, Dr. J. C. Geiger, has issued a proper warning:[5] "The Director of Public Health wishes to record the fact that he disapproves the present tendency of manufacturers to add measured quantities of vitamins to foods for commercial purposes. The insufficient and incomplete scientific knowledge available at this time on the possible effects of the consumption of vitamin-reinforced food products over indefinite periods of time fully justifies the attention that caution should be observed in the use of such products. There is still considerable question, particularly in the instance of vitamin D, of what constitutes the proper dosage of vitamin concentrates in the various age groups. Any attempt to increase the sale of a food product, especially milk, by the addition of a substance whose value to the public health is still a controversial problem is indeed ill advised, since the final evidence, to be determined by research methods, has not yet been secured. Even if it is granted that the actual danger in the consumption of vitamin D milk is relatively minimal, there is as yet no definite and accepted information on the limits or margins of clinical safety. Under these circumstances, therefore, it is believed that the administration of such products should be surely in the province of the physician, and not in that of the commercial distributor or manufacturer of food products."

Protective Foods.—Protective foods should be included in the menu of every man. These foods are particularly rich in vitamins, and you need vitamins to remain in health. The protective foods include leafy vegetables, fruits, and milk. Medical and scientific studies have demonstrated that their use aids in warding off disease, and so helps to increase the life span.

Leafy vegetables include lettuce, romaine, spinach, kale, cabbage, cauliflower, dandelion greens, turnip and beet tops, celery, and endive. Besides these, although not leafy vegetables, string beans and tomatoes are rich in protective substances. Every full meal should include two cooked vegetables as well as a vegetable salad, the latter preferably of raw vegetables, such as lettuce, tomatoes, celery, and carrots.

Oranges, grapefruit and lemon, in other words, the citrus fruits; bananas, apples, apricots, grapes, plums, pears, canteloupes, figs, pomegranates, are rich in vitamins, especially vitamin C, and should be eaten freely.

Every man should drink at least a pint of milk every day, for milk is the most nearly perfect food known. Dairy products, cheese and butter, also are fine for health. Both milk and cheese are rich in calcium, a mineral which the body must have.—Dr. John L. Rice, Commissioner of Health, New York City.

TUMORS AND CYSTS OF THE LUNG: DIAGNOSTIC METHODS*

By J. J. Singer, M.D.
St. Louis, Missouri

There are many who are of the opinion that tumors of the lung are increasing; but whether this conclusion is due to our greater skill in recognizing the condition, or whether tumor of the lung is really becoming more prevalent is still under consideration.

DIAGNOSIS OF LUNG TUMORS

The diagnosis of tumor of the lung may be difficult because the first manifestation may be atelectasis, pleural effusion, bronchiectasis, spontaneous pneumothorax, or empyema. If one is aware that the complication caused by the presence of a tumor may be the first warning, and a careful search is made for the primary cause, a correct diagnosis can readily be made. There are two types of tumor of the lung—benign and malignant. This refers to the cellular content of the tumor, but the physical state of the benign tumor may be such that it becomes malignant by producing pressure on important structures, and for this reason it is advisable to consider all tumors of the lungs as malignant. There are many types of tumor in the lung—mediastinal, pleural, and thoracic cage—and it is sometimes difficult to locate the disease, especially in the ordinary x-ray studies.

DIAGNOSTIC METHODS

Methods have been developed which do make the diagnosis easier now, and it is our purpose to discuss these in the order in which we have used them:

1. Clinical history.
2. Physical findings.
3. Fluoroscopic findings.
4. Roentgen ray.
5. Bronchography.
6. Bronchoscopy.
7. Biopsy.
8. Diagnostic pneumothorax.
9. Examination of pleural fluid and sputum.
10. Exploratory thoracostomy.

CLINICAL HISTORY

The clinical history of the patient is most important and easily elicited if only the condition of tumor is thought of.

Cough, dyspnea, and hemoptysis by themselves are not diagnostic; but if present in a patient of "cancer" age, then these symptoms become more important. Pain localized in the chest is most significant, since no other pathologic condition seems to present this constant distress. Dyspnea is a very common symptom, and in conjunction with cough and pain is most important. Loss of weight, strangely enough, is not noted very often, except in advanced cases.

PHYSICAL FINDINGS

It is obvious that physical findings cannot be conclusive. The signs are often due to the presence of abnormal tissue in the lung. The size of this, the location, and the densities determine the signs. It is important in analyzing the symptoms to remember that intrabronchial tumors may be small, but if atelectasis develops, one can find dullness, bronchial breathing and distortion of cardiac dullness. There are no definite signs leading to a diagnosis of carcinoma of the lung. In cases of long duration the signs of bronchitis, pleural effusion, abscess of the lung and bronchiectasis overshadow the tumor signs.

The laboratory findings are considered under physical signs; and here again there are no definite signs except in the study of pleural fluids, which will be discussed later.

FLUOROSCOPIC FINDINGS

Fluoroscopic examination follows the study of physical signs. Where signs of atelectasis or fluid are obtained the fluoroscopic examination should confirm them.

By proper "positioning" the patient before the fluoroscopic screen, one obtains pictures of the lung from all angles, and this part of the examination makes it possible to see even behind a large shadow, that is, if the shadow is due to a density in the posterior part of the chest when viewed from the anterior, and this shadow is increased in size; but when viewed posteriorly this shadow is smaller and then parts of the lung which were hidden before now become visible.

Occasionally fluid complicates this density by massing shadows, but when the patient is turned on one side or the other it is possible to shift the fluid, especially if air is introduced (diagnostic pneumothorax), so that the various masses can be individually seen.

ROENTGEN FILMS

When, by fluoroscopic studies, we have found these individual shadows in certain positions, then roentgen films are taken to make permanent records. It is also important in obtaining the proper density in films by more or less exposure, which must be determined after fluoroscopic examination. Roentgen rays give us a definite picture of the state of the lungs, but much study must be given to the relation of abnormal shadows to the structure of the lung, heart, and diaphragm.

BRONCHOGRAPHY

Bronchography is the one procedure in roentgen-ray studies that has been most helpful to us in determining the patency of the bronchial tree, the location of lung in relation to fluid and to the mediastinum. The introduction of the iodized oil into the lung is quite easy. Several years ago I described a method of instilling this oil merely by

Fig. 2.—Lipiodol outlines lower portion of cysts in left lung and many cysts in right.

Fig. 3.—When patient was placed with left side up, the iodized oil shows the walls of numerous large cysts in the left lung and a few smaller cysts in the right lung. Note pneumothorax pocket in lower left chest cavity below cysts. When air was absorbed, the pleural leaves became adherent. No further leak from cysts occurred. With this condition the patient has been clinically well.

pulling out the tongue and dropping oil directly into the pharynx without the use of a local anesthetic. We have used this method many times and have been successful in most cases.

BRONCHOSCOPY

Occasionally one encounters patients who cannot control the gag reflex, and then we use a cocain spray in the pharynx. Bronchoscopic instillation of oil is done when it is otherwise necessary to use the bronchoscope.

BIOPSY

The most important aid to the exact diagnosis of carcinoma is the biopsy specimen. When the microscopic examination of pleural fluid is positive, this part of the study must be made by qualified persons, as debatable interpretation will lead to false treatment. In so serious a condition as carcinoma, the less doubt on the diagnosis the better. The bronchoscopic study of the bronchial tree with biopsy represents the final approach to the diagnosis. The observer can see the location of the tumor, color, size, etc. If the location of the tumor is sufficient distance from the carina, then surgical removal might be considered.

THORACOSCOPY

Occasionally when there is fluid in the pleural cavity this can be replaced with air; then by introducing an operative thoracoscope it is possible to not only see the tumors on the pleura and visceral portion of the lung, but specimens can easily be removed.

The aspirated fluid is centrifuged, the cells are embedded in paraffin, hardened, then sectioned and stained. This procedure has given many positive diagnoses when other means failed.

Fig. 7.—Lateral view showing the walls of various cysts with droplets of oil adhering to walls in many areas.

CYSTS OF THE LUNG

The great interest recently manifested in cystic disease of the lung has shown that cysts are more common than were suspected. It has been evident to those interested that certain abnormalities of the chest, such as congenital cysts, abscess lung, spontaneous pneumothorax and some large bronchiectasis, have not been absolutely correctly diagnosed; now the correct diagnosis can be made if congenital cysts are kept in mind.

We have been fortunate in having seen fourteen cases of congenital cysts of the lung in the past three years. In the earlier cases the diagnosis was not made at the time of the examination. The important diagnostic features are often not evident until complications arise, such as infections and spontaneous rupture of cysts with consequent pneumothorax and more or less displacement of the chest contents.

In a suspected case of congenital cysts we must depend primarily on roentgen-ray examination, particularly with the use of iodized oil, this substance being introduced into the lung by the aspiration method or by bronchoscopic control. When this method is used, one usually sees malformation of the bronchial tree. The lung tissues are decidedly abnormal, and often only a small amount of lung tissue is present and the large space in the chest is usually filled with air, but occasionally fluid is found with levels. If the main bronchus is closed, it will be necessary to introduce air (diagnostic pneumothorax) and probably iodized oil directly into the cyst cavities. By turning the patient in various positions, the oil outlines not

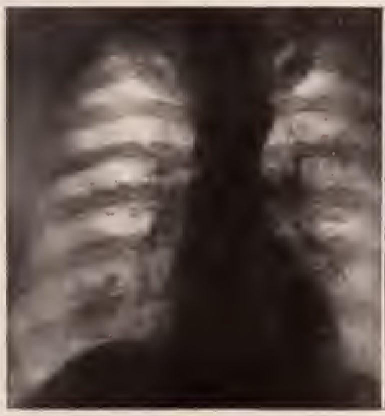

Fig. 8

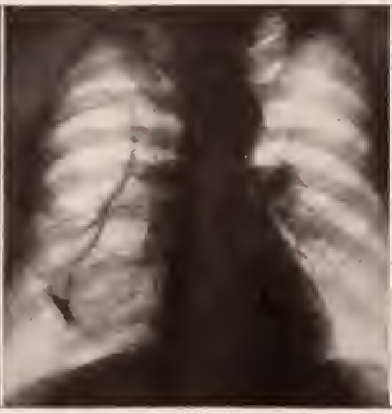

Fig. 9

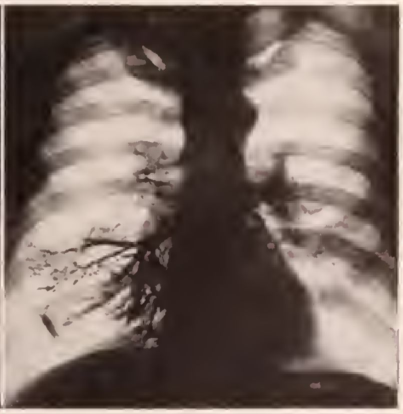

Fig. 10

Fig. 8.—B. S. Film taken March 4, 1930. The faint outline of cyst in right costophrenic angle. At this time only occasional wheezes were heard.

Fig. 9.—November 5, 1934. Shows many cyst walls with small pocket of pneumothorax in extreme right base. Emphysematous cysts or giant bullae.

Fig. 10.—November 14, 1934. Lipiodol shows right lower lobe with compressed bronchi, with no oil in cysts. (Openings into cysts are so tiny that a ball-valve action must have been present.)

only the cyst walls, but the fine irregular bands within the cavity are noted.

Some of the most dramatic pictures we have seen are produced by the use of iodized oil and the true anatomical conditions are easily demonstrated. By diagnostic pneumothorax we can push over the contents of the chest cavity with the cysts and the malformed lung.

In a recent case seen, a spontaneous pneumothorax with marked displacement developed following rupture of the cyst. This was followed by an effusion. When the fluid and air were aspirated, the cyst walls became adherent to the chest wall, obliterating the pleural cavity. No further spontaneous pneumothorax developed. The patient has been clinically well since, although the cysts remain.

This accident suggested a treatment for the recurring rupture of cysts; that is to produce an artificial pneumothorax and introduce lipiodol or gomenol to produce a slight pleuritis which may result in a symphysis of the pleural leaves.

Another suggestion for treatment is the cauterization of the main bronchus leading to cysts. Complete closure of the bronchus would prevent further air from entering cysts, so that the air within would be absorbed and the cavity collapsed.

Theoretically, this is good, but practically I believe that only in exceptional cases would the desired effect be produced.

In several cases where spontaneous pneumothorax developed, the cysts did not collapse, but were forced into the opposite side. Furthermore, in one case a thoracoplasty and phrenicectomy produced the same result.

In infected cysts the treatment has been drainage and removal en masse.

COMMENT

Sauerbruch states that upon a development basis it is conceivable that a bronchus may be "tied off" when the lung is being enveloped by pleura, and that if a large bronchus should be so affected, then a large cyst of the lung should result. If the middle-sized bronchi should be involved, then smaller cysts should develop and, if this typing-off should occur during the last intra-uterine development period, then multiple small cysts or congenital bronchiectasis should be the result. A superimposed infection, measles, scarlet fever, whooping-cough, would make evident the underlying condition, and we should then have bronchiectasis as it is seen clinically. As we have noted in the preceding paragraph, however, it is difficult to understand how air can be present in the cysts if the bronchi are obstructed during intra-uterine life.

During prenatal life the future respiratory passages are filled with a liquid (presumably amniotic fluid). Before breathing, the living cells of the alveoli are irregularly cuboidal with round nuclei. After respiration has occurred, the nuclei become spaced farther apart, the cytoplasm drawn out, and the cells appear very flat and thin. The blood vessels then become distended and more conspicuous.

There is some evidence which strongly suggests that even during intra-uterine life respiratory movements occur at times, and that these attempts at respiration must result in the aspiration of more amniotic fluid into the lungs. This occurrence, however, is not incompatible with a normal existence after birth. Graham showed, experimentally on guinea pigs, that if even a moderate degree of asphyxia of the fetus is produced, respiratory movements occur which, if the asphyxia is sufficiently extreme, pass into general convulsions. If the fetus is near term it may develop normally, after delivery by cesarean section, despite vigorous respiration of fluid into the lungs. The explanation of how the animal can live after the aspiration of the fluid is perhaps to be found in the fact that the lungs do not become fully distended with expanded alveoli until after air has been breathed, and that the comparatively small amount of liquid which is aspirated is not sufficient to prevent the proper degree of inspiration of air to carry on respiration. Of interest in this connection are the experiments of Geyl, who injected dyes experimentally into the amniotic sacs of animals.

Ewart, Wilson, and others, have shown that the lung of the child is just as complex in structure as that of the adult. Subsequent growth apparently depends upon an increase in the size of the alveoli without any addition to their number.

DEVELOPMENTAL ANOMALIES

According to Hueter, many of the cases of so-called congenital bronchiectasis are due to developmental anomalies in the bronchial tree. If the arrest in development is early, only large bronchi are formed and the rest of the lung may be a sac.

REPORT OF CASES

Case 1.—N. D. The patient concerned is an 18 months old male child who developed an acute attack of dyspnea, cyanosis, spasmodic cough and fever at the age of fourteen months. This attack followed an acute upper respiratory tract infection. Before the child was seen by us, the mediastinal contents were found to be displaced to the right, and closed drainage of the left pleural cavity, low down, was established elsewhere. No improvement followed the above procedure, and the tube was withdrawn after a few days. The skin wound healed over. A bronchoscopic examination at this time was negative. From then on the child obtained some temporary relief as a result of daily aspirations of over 1,000 cubic centimeters of air from the left upper chest. A fluoroscopic examination at the Barnes Hospital on August 5, 1931, which was about twelve weeks after the onset of the child's illness, still revealed the fact that the mediastinal contents were displaced to the right. The left diaphragm showed paradox movement. This fact, together with the above, suggested that the air pocket above the left diaphragm was a tension pneumothorax. A needle was introduced high up in the left upper chest. The pressures were plus 20 and plus 18. Eight hundred cubic centimeters of air were then withdrawn with the aid of a pneumothorax apparatus. The pressure then registered plus 6 and plus 4. The mediastinal contents had returned to their normal position. The child experienced great relief from this aspiration. Six cubic centimeters of lipiodol were then introduced through the same needle. The oil dropped to the bottom of one of the cysts of the left lung, and under the fluoroscope one could see the oil run over both main bronchi into the opposite lung. The air pocket over the left diaphragm failed to be injected. The lipiodol injection demonstrated beyond doubt that the condition was one of bilateral congenital cystic disease of the lung. This type of cystic disease is often considered to be a form of bronchiectasis, and is frequently associated with smaller dilatations and with acquired bronchiectasis. The latter develops as the result of repeated infections. A communication from Doctor Croswell on September 24, 1931, stated that the child had developed a left-sided pleural effusion and that the mediastinal contents had returned to their normal position following the aspiration of a small amount of fluid. Further aspirations of air then became unnecessary. The perforation in one of the cysts, which was allowing the escape of air into the left pleural cavity, had undoubtedly become sealed off.

* * *

Case 2.—R. G. Patient is a seven-year-old male child, admitted to St. Louis Children's Hospital April 3, 1934.

P. I.: Loss of appetite, irritable, loss of weight, dyspnea. Measles at five months. Fell from high chair at eighteen months. On examination a pneumothorax was found to be present. Air aspirated frequently without permanent benefit.

April 4, 1934.—A needle was introduced in right chest and manometer readings taken, initial pressure minus 3 minus 7, and 40 cubic centimeters of air were withdrawn; final pressure minus 10 minus 7. The reading here would lead one to believe needle in pleural cavity and not a cyst. On fluoroscopy no evidence of an air pocket between the cyst wall and parietal pleura was found.

April 5, 1934.—Bronchoscopic examination by Dr. M. F. Arbuckle. Trachea was markedly displaced to the left and compressed so that the lumen was one-eighth of the usual size, and was in a figure-of-eight with the center of eight solid, *i. e.*, the right wall of the trachea was pushed over into contact with the left wall. Lower down, the right lung was pushed over so that the view of the carina was effaced. The bronchoscope could not be inserted in the right bronchus; however, the instrument was passed readily into the left main bronchus.

April 7, 1934.—Vital capacity, 500. Hemoglobin, 80 per cent; red blood cells, 5,600,000; white blood cells, 8,000. Urine negative.

April 10, 1934.—Lipiodol injected into lung through the larynx. Found only a rudimentary bronchus (see Fig. 5). Twenty cubic centimeters of lipiodol were introduced into the cyst. The patient was turned on the stomach, on the back, and then sat upright. X-ray films show that there were many cysts of varying size with all communicating with each other. Thin trabecula are noted in lower cysts, and some of the pockets are heavily filled with the iodized oil. The exact nature of the condition is beautifully noted by the films taken in various positions. I have several times had occasion to insert a thoracoscope directly into the cysts, and found the condition present as outlined.

This boy, after the introduction of oil into the pleural cavity, developed symphysis of the pleural leaves, and has in the past three years been clinically well, although cysts are still present, but as long as the left lung compensates, and no infection takes place in the cysts themselves, he will remain well.

* * *

Case 3.—B. S. This 45-year-old male was admitted to the hospital November 14, 1934, with a history of wheezes, orthopnea, and cough for the past four years. Diagnosis of asthma was made on the basis of these symptoms. There was a strong familial history of asthma. Of late the patient has become increasingly short of breath on exertion.

In 1929 he had the first attack of so-called asthma, but physical signs were indefinite. A film (see Fig. 8) was taken. No suggestion of cysts was recognized by his physician at that time, but in the light of present condition the dense streak in lower right base was the outline of the first cyst. This patient was accustomed to severe physical exertion—horseback riding, tennis, golf, walking, etc. It was not until 1934, in August, when he had severe pains in the right chest that the true condition was noted. On examination by his doctor a right partial pneumothorax was discovered. A physical examination revealed diminished breath sounds in both lungs with hyperresonance; no increased whisper. Fluoroscopy and x-ray showed large emphysematous cysts of right lung with rupture at the base (spontaneous pneumothorax). Lung tissue was seen through the cysts. Evidently the cyst had ruptured and the air confined to the base, because of adhesions in the upper portion of the chest. Lipiodol did not enter the cysts, but many bronchi showed blocking with air trapped beyond it (obstructive emphysema). No attempt was made to aspirate the air from pneumothorax pocket because of the small amount present.

The emphysymatous blebs became larger and even intercommunicated. The pressure exerted on the other portions of the lung produced the dyspnea.

Treatment: No medical treatment for this type of cyst other than symptomatic.

The most important consideration is to limit activity to the lowest threshold.

A MEDICAL SURVEY OF ONE THOUSAND WORK RELIEF PERSONS*

CERTIFIED FOR WORK RELIEF IN SAN FRANCISCO: PERIOD OCTOBER 2 TO 19, 1935

By Albert E. Larsen, M.D.
San Francisco

This survey was made to acquaint ourselves with the physical condition and medical problems among the people on relief. The San Francisco medical plan, with its centralization of all medical information of people on relief, with a part-time medical staff familiar with the workings of the relief administration, offered ideal facilities for such a study.

PRELIMINARY QUESTIONS

An examination blank was designed to bring to light statistically several of the major medical problems about which there seemed to be some controversy. At the same time, it was thought advisable to investigate several of the major public health problems that, theoretically, would exist in such a group. The questions were taken by an interviewer just preceding the actual medical examination. They read as follows:

1. Number of people in the family under the age of six? Are they vaccinated?

This question was designed to ascertain whether or not the preschool child was able to have the advantage of immunologic procedures so important to the individual and the community at large.

2. Anyone chronically ill in the family? Cough? This was designed to bring out possible hidden cases of tuberculosis.

These two questions, if answered in the affirmative, were sufficient cause for medical-social investigation, after which a proper dispensation of the problem would be effected.

3. Have you been ill during the past six months? Designed to determine the approximate incident of illnesses in the group.

Following this question the applicant was asked: Have you been under the care of a private physician? If so, have you been able to pay him in full, partially, or none? The purpose of this question was to learn where these people were accustomed to go for medical care, and to determine in what measure the relief load was economically dependent on the medical profession.

The applicant was then asked if he had attended a clinic—the name and his out-patient number. This would show again the economic

NOTE: The findings are listed in sample groups taken consecutively for one thousand cases. This is done to show the consistency with which certain history and physical findings appear.

load private agencies might be expected to carry. It also was of medical value should the applicant become a patient of the E. R. A. His former medical record would then be automatically requested, obviating reduplication of medical time and costly medical procedures.

The last question, "Was illness a factor in causing you to seek relief?" has many medicosociologic implications, such as the cost of medical care, the incidence of disabling diseases, and the community's responsibilities. No attempt was made to break this question into its many possible ramifications.

THE MEDICAL EXAMINATION

On the completion of this questioning, the person was examined by a physician. A detailed, clinical history, with particular emphasis on the patient's present condition, was noted. A complete physical examination was then made.

If the applicant gave a history of being on relief, and had been a patient of the Central Medical Bureau, his medical record was gotten, to supplement the physician's examination.

CLASSIFICATION OF PERSONS EXAMINED: FOUR GROUPS

At the conclusion of the examination the physician was called upon to classify the individual into one of four types—"A," "B," "C," or "D."

While recognizing the difficulty in many instances of so classifying individuals into types, it was nevertheless necessary to define each that a standard could be established.

An "A" type is physically robust and organically sound.

A "B" type is physically frail, but organically sound.

A "C" type is one with a demonstrable organic lesion, such as hernia, varicose veins, heart murmur, etc., not producing symptoms.

The "D" type has a demonstrable organic lesion which would interfere with the normal activities of the individual concerned.

While the fundamental object of such a classification is to define the ability of an individual to work, it cannot define what type of work the applicant could perform. This decision must eventually rest with intelligent placement procedures. The "A," "B" and "C" types are eligible for placement. The "C" type must be placed in work which would not aggravate the ailment found on physical examination. The "D" types are presumably unemployable.

MEDICAL RECORDS

The medical record is meant to be part of the social service case history, and should be used in conjunction with the individual's employment history before a final decision of case dispensation can be made.

The one thousand cases thus examined represent the natural intake flow from October 2 through October 19, 1935, with the addition of a small percentage of individuals on relief requiring reconsideration of their work status. During this time there were no major labor moves such as strikes, which might have altered the type of individual examined. The appended chart shows the findings as they appeared during the course of study.

The headings used are general in nature, but represent the results of detailed questioning and weighing of evidence on the part of the examining physician. Thus:

Cardiac symptoms means that in the opinion of the physician the individual was not able to perform ordinary physical exertion without distress, shortness of breath, swelling of the ankles, heart pain, dizzy spells, or fainting attacks.

Gastro-intestinal symptoms include "indigestion," abdominal pain, gas on the stomach, diarrhea, nausea and vomiting, etc., of sufficient intensity and duration to warrant being called abnormal.

Rheumatism includes lumbago, aching, stiff or swollen joints, and neuritis, of sufficient intensity and duration to warrant being called abnormal.

Genito-urinary complaints on the same basis refer to prostate disease or possible kidney complaints.

Backstrain includes a definite history of injury, after which there may have been a recurrence when subjected to heavy labor, and the chronic type of backache on a postural or rheumatic basis, or for some undetermined cause.

Nervousness is difficult to evaluate on an examination with limited time. It was noted positive when there was a history of a nervous breakdown, nervous wreck, "nerves" and "worries."

In the physical examination:

Poor mouth hygiene means in most instances extensive pyorrhea, cavities, tooth snags and uncleanliness, to a sufficient degree to be evidenced by a single glance.

Impaired hearing is noted only when the impairment is of such a degree as to interfere with conversation at slightly increased voice intensity.

Chest pathology may include râles in the chest, asthmatic squeaks, chest deformities, changes produced by tuberculosis or by congestion from a failing heart.

Irregular pulse means frequent dropped beats or complete irregularities, such as auricular fibrillation.

Blood pressure positives include all cases with systolic blood pressures over 150 and diastolic pressures over 100.

Central nervous pathology indicates paralysis, Parkinsonian tremors and abnormal reflexes.

Mental aberration is noted when the physician is impressed with a marked personality change, such as "peculiar," paranoid tendencies and senile mental changes.

Abdominal pathology is noted when there is a tenderness supported by a history of gastro-intestinal symptoms or an enlarged organ such as liver or spleen.

Arthritis includes swollen joints, tender spine, tender sacroiliac joints and deformities on an arthritic basis.

Impaired function includes stiffened joints, paralysis, loss of fingers, deformities from burns and poorly-set fractures, or any condition which would be a handicap to an individual performing manual labor.

Impaired vision ranges from loss of sight in one eye, impaired because of cataracts, or marked refraction errors not corrected with glasses.

Skin diseases include scabies, pediculosis, ulcerations, impetigo, and eczema.

Senile is used where marked arteriosclerosis is noted, together with a general appearance of feebleness.

Miscellaneous are definite disease entities either diagnosed by the examining physician, given as the individual's statement, or taken from a former medical record.

Treatment necessary is noted when there is some condition present which the physician feels should have care immediately, such as infected wounds, an infectious disease, diabetes, tuberculosis, and in conditions where the physician is not satisfied with his examination and would like to have the benefit of possibly an x-ray, Wassermann, etc., before passing judgment.

THE CHART NOTATIONS

There are several points in Table 1, which, though self-evident, should be emphasized. Of the 47.4 per cent of people who claim to have had some illness during the past six months, 33.7 per cent sought clinic care, while 1.1 per cent sought advice from a private physician. This leaves a balance of 15.6 per cent who, while claiming to have been ill, had not sought medical care.

The high percentage of cardiac symptoms may be accounted for by the high percentage of people falling into the age group over 45—69 per cent, where most cardiac pathology is apt to appear. The high incidence of rheumatism and gastro-intestinal symptoms probably has a similar explanation. The poor food habits of people on relief must also be considered to have a possible etiologic significance. The genito-urinary percentage—9.9 per cent—may also be accounted for by the age group and the male predominance; for in most instances the complaint is related to possible prostate disease. In the physical examination poor mouth hygiene is an outstanding finding. The 32.5 per cent whose mouths are in such bad condition present a major public health problem.

The incidence of high blood pressure may again be explained by the age group, where it is expected to find a high incidence of hypertension.

The high incidence of hernia and varicose veins represent conditions which are amenable to treatment. Their treatment is costly and time-consuming. Their presence closes to the individual the ordinary outlets of employment. It suggests an economic and medical question of considerable importance since 20 per cent of the employable people have either one or the other, or a combination of both.

FINAL RESULTS OF THE SURVEY

The final results of the survey show 26.7 per cent Class "A," 30.2 per cent Class "B," 36.5 per cent Class "C," and 6.5 per cent Class "D." The percentage of Class "C" type is considerably higher than expected. It explains in a measure the 13.4 per cent of the people who have sought relief because of illness. Their ailments are a definite handicap in competing with others for positions available in private industry.

The sampling statistics show a remarkable consistency from one group to another, which suggests that a similar condition probably exists throughout the entire group of the unemployed.

It is possible, therefore, that the existence of this "C" group is in a measure responsible for the persistence of the present relief load.

MAPHARSEN: ITS USE IN THE TREATMENT OF SYPHILIS*

By Hiram E. Miller, M.D.
Norman N. Epstein, M.D.
and
Roger G. Simpson, M.D.
San Francisco

Discussion *by Chauncey D. Leake, Ph.D., San Francisco; George V. Kulchar, M.D., San Francisco; Ernest H. Falconer, M.D., San Francisco; Howard Morrow, M.D., San Francisco.*

Mapharsen is chemically meta-amino-para-hydroxyphenylarsin oxid and is a trivalent arsenical identical with arsenoxid. This drug has been recently introduced by Dr. O. H. Foerster and his associates [1] for the treatment of human syphilis.

In this report we wish to present our observations on the clinical use of mapharsen in the treatment of syphilis for the period of March, 1934, to the present time.

HISTORICAL BACKGROUND AND REVIEW OF THE LITERATURE

Ehrlich [2] synthesized arsenoxid about 1912 while working on the arsphenamins. He thought it was too toxic for clinical use. It was put aside until 1920, when Voegtlin and Smith [3] showed that the arsphenamins formed arsenoxid when oxidized in the tissues, and that this product was the active treponemacidal agent of the drug. Voegtlin considered its possibilities for clinical use, but abandoned the idea because the maximum tolerated dose seemed to be too nearly the minimum curative dose for safety. Rosenthal [4] showed that only 10 to 12 per cent of arsphenamin is converted into arsenoxid within the body. In 1934, Tatum and Cooper [5] reinvestigated its use in experimental syphilis and experimental trypanosomiasis, and showed that the pure arsenoxid was not dangerously toxic and possessed a therapeutic index greater than neoarsphenamin. They designated the drug as "mapharsen," from its long chemical term: *m*eta-*a*mino-*p*ara-*h*ydroxyphenyl*arsine* oxid.

Raiziss and Severac [6] recently found that the therapeutic index of neoarsphenamin was three times greater than that of arsenoxid in experimental trypanosomiasis, and five and a half times as efficient as arsenoxid in experimental syphilis of rabbits. They state that in experimental syphilis of rabbits the maximum tolerated dose and the minimum curative dose for arsenoxid are very nearly identical, which suggests that the clinical use of this drug in adequate curative doses might be fraught with considerable danger.

In a recent paper, which deals with the experimental use of mapharsen in animals, Gruhzit [7] reported that the drug was not found to be toxic to the kidneys, did not produce albuminuria, or elevate the total nonprotein nitrogen of the blood or the blood sugar. For Treponema equiperdum infection in rats the therapeutic indices for mapharsen, arsphenamin, and neoarsphenamin were found to be 18, 14, and 9, respectively. The therapeutic indices in syphilis in rabbits were 7 and 5, respectively, for mapharsen and neoarsphenamin. The sterilizing indices in single doses were about 4 for mapharsen, and 3.75 for neoarsphenamin, while in repeated doses given once weekly for three weeks the respective indices were 4.6 and 1.67 for mapharsen and neoarsphenamin. Thus with single doses the sterilizing indices were about equal, but with repeated doses mapharsen appeared superior to neoarsphenamin. The experimental work further indicated that 1.0 milligram per kilogram of body weight was tolerated well and was the optimum dose for prolonged use.

Foerster and his associates have conducted a clinical trial of mapharsen in the treatment of syphilis. They used the drug alone, unsupported by other therapy, in a series of eighty cases, of which twenty-three patients were treated for twelve to eighteen months. They found that the drug was tolerated well and without serious toxic effects, and that it possessed antisyphilitic properties which justified more extensive study.

CLINICAL OBSERVATIONS

Upon the basis of the clinical and experimental work reported above, the use of mapharsen was begun in the outpatient department of the University of California Hospital in March, 1934. In order to determine the therapeutic efficiency of the drug, mapharsen was substituted for neoarsphenamin in the schemes of treatment for various forms of syphilis, which consisted of alternating courses of the arsenical and bismuth salicylate. The dosage of mapharsen employed was .04 gram dissolved in 10 cubic centimeters of distilled water for females, and .06 gram for males—approximately one-tenth of the amount of arsenic as in the equivalent dose of neoarsphenamin.

Read before the Dermatology and Syphilology Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

PATIENTS UNDER TREATMENT

To date four hundred patients have received 13,240 injections of mapharsen, totaling 662 grams. Of this group, many are unsuitable subjects for a study of the therapeutic value of mapharsen because some of these patients had received various kinds of antiluetic therapy before coming to the clinic; many had already been under treatment with neoarsphenamin; and some disappeared or were transferred to care elsewhere. Of this number, sixty-three were treated with mapharsen as the only arsenical. While the results obtained with the rest of the group do not give exact information as to the therapeutic effectiveness of mapharsen, a study of this clinical data does show certain valuable facts as to the toxicity and general tolerance of the drug:

Sixty-three received mapharsen as the only arsenical; 293 received both mapharsen and neoarsphenamin, and tolerated both drugs equally well; 31 did not tolerate neoarsphenamin, and did well on mapharsen; 6 tolerated neither drug well; 2 did not tolerate mapharsen well, but did well on neoarsphenamin; 5 could not tolerate any form of arsenic (neoarsphenamin, mapharsen, or bismarsen). Total number of patients in the series of cases investigated was 400.

GROUP RECEIVING MAPHARSEN AND BISMUTH

Of special interest is the group of sixty-three patients who received mapharsen only as an arsenical, together with bismuth intramuscularly. Thirty-four of these have become and have remained blood-Wassermann and Kahn-negative. Twenty-nine are still under treatment and are progressing satisfactorily, but their blood-Wassermann and Kahn reactions have not yet become negative. Analyzing the thirty-four cases, we find:

Four cases, seronegative primary syphilis; all remained serologically negative.

Nine cases, seropositive primary syphilis; blood-Wassermann and Kahn reversal in an average of 4.1 months.

Fifteen cases, secondary syphilis; blood-Wassermann and Kahn reversal in an average of 7.8 months.

Six cases, latent syphilis; blood-Wassermann and Kahn reversal in an average of 14 months.

Table 1 shows the average number of injections of mapharsen and bismuth salicylate which were given before the blood-Wassermann and Kahn reversal occurred:

Table 1.—*Average Figures for the Above Group of Cases*

Diagnosis	No. of Injections of Mapharsen	Total Gm. Mapharsen	Total No. of Injections of Bismuth
Primary ..	14.6	.81	12.9
Secondary	16.9	.84	15.1
Latent	24.3	1.29	37.3

Since the blood-Wassermann and Kahn tests were done at three to five months' intervals, a reversal may have occurred much sooner than is shown here. Thus these figures do not specify the earliest time of reversal.

COMMENT

In all the patients with early syphilis, the primary and secondary lesions responded rapidly to mapharsen. The chancres showed healing in forty-eight hours, and were nearly imperceptible in fifteen days. The cutaneous lesions involuted promptly, usually disappearing within one to two weeks. Thus the visible lesions of early syphilis responded rapidly to mapharsen, and this is comparable to the response seen with neoarsphenamin. There have been no clinical or serologic relapses up to the present time in patients adhering to regular treatment.

From the above analysis of the total group, it is seen that the majority of patients (293) are able to tolerate both arsenicals equally well without untoward reaction.

Thirty-one patients did not tolerate neoarsphenamin well because of severe nausea and vomiting, and their dosage had to be repeatedly cut down to inefficiently small amounts. These patients were changed to mapharsen and were able to continue with an average-sized dose of the drug. Thus it would appear that mapharsen can be used in certain instances where neoarsphenamin is not tolerated. Certain patients are thus able to continue with an arsenical in a fair-sized dose. This would not be possible if mapharsen were not available.

In two patients mapharsen was not tolerated well, but neoarsphenamin was taken without discomfort.

Six patients were unable to tolerate an effective dose of either mapharsen or neoarsphenamin because nausea and vomiting followed the injections.

Five patients who had had an exfoliative dermatitis from neoarsphenamin had a recurrence of this dermatitis when given mapharsen in small doses, *i. e.*, .01 gram. It is of interest to note that in all of these patients the patch-tests for mapharsen were negative. These patients were apparently sensitive to arsenic in any form, since they reacted also to bismarsen intramuscularly, and one of them even to mercury salicylate.

UNTOWARD REACTIONS

The one unpleasant reaction peculiar to mapharsen is the dull, aching pain it produces along the course of the veins, persisting for a few minutes to several hours after the injection. This pain goes deep into the arm and shoulder, and sometimes downward into the forearm and hand. In none of the patients of our series was the pain sufficiently severe to cause discontinuance of the use of the drug. Attempts to lessen the severity of the pain by allowing the solution to stand for some time before injecting were unsuccessful. Patients complained less when the injection was given rapidly. No thrombosis of veins was noted in any of these patients.

Another untoward reaction encountered during the use of mapharsen is mild nausea and sometimes vomiting, which come on from fifteen minutes to two hours after the injection and last one-half to three hours. Refraining from the meal preceding the injection tends to lessen the occurrence of these symptoms. Most patients have this discomfort only following the first few treatments. As previously stated, these gastric upsets are much less common and less severe with mapharsen than with neoarsphenamin.

In the 13,240 injections given to four hundred patients, we have not seen a case of jaundice, recognizable by the icteric tint of either skin or sclerae. We did not note enlargement of the liver in any of these patients.

Not as common, but of more serious consequence is the complication of toxic skin reactions—the precursor of an exfoliative dermatitis. These appeared as pruritic erythematous eruptions which, after a few weeks' rest (using bismuth meanwhile) did not reappear upon resuming the mapharsen.

Purpuric eruptions, in the form of large widespread purpura, occurred with several trials of neoarsphenamin in two cases, but did not occur when mapharsen was given.

In this series mapharsen has caused no nitritoid reactions, no Herxheimer reactions of consequence, and no deaths.

CONCLUSIONS

Mapharsen is suitable for use in the treatment of syphilis when the proper dosage is employed. The amount of mapharsen required for therapeutic usefulness is generally well tolerated by the patient.

The drug is a potent antisyphilitic remedy, and should be studied further before its place in the treatment of syphilis can be definitely established.

SUMMARY

In a clinical trial upon four hundred cases of syphilis, it was found that mapharsen:

1. Is safe to use, as shown by the 13,240 injections given to four hundred patients.
2. Causes rapid healing of visible lesions.
3. Effects and maintains a Wassermann reversal within a reasonable length of time.
4. Is less toxic than neoarsphenamin.
5. Can generally be used where neoarsphenamin is not tolerated. Patients are thus able to continue with an arsenical in adequate dosage. This would not be possible if mapharsen were not available. ✓ yes. not dehydrocholate.
6. Causes no nitritoid reactions.
7. Causes no Herxheimer reactions of consequence.
8. Causes no deaths.

DISCUSSION

Chauncey D. Leake, Ph.D. (University of California Medical School, San Francisco).—An important point in considering the therapeutic hazard involved in the use of any drug is the margin of safety existing between the average effective dose and the minimum dose at which any toxic symptoms may appear. Mapharsen is certainly as safe as the arsphenamins when considered from this standpoint, and has many clinical advantages in reducing the possibility of nitritoid and Herxheimer reactions. It is very likely, as implied by Voegtlin's work, that these reactions are brought about in the gradual transformation of the arsphenamins in the body to arsenoxid or some other compound similar to mapharsen. Some of the commercially inspired criticisms of mapharsen point out that it is much more toxic than the arsphenamins. This is true from the standpoint of total toxic dosage, but not from the standpoint of the relation of the toxic to the effective dose. Mapharsen is effective in a much lower dosage than the arsphenamins, and has fully as wide, if not as wide, a margin of safety between the effective dose and the toxic dose. Mapharsen has been carefully developed on a sound pharmacologic and clinical basis, and constitutes a definite advance in drugs available for the treatment of syphilis. The report by Doctors Miller, Epstein, and Simpson is a sound appraisal of the drug from a critical and impartial standpoint.

⁂

George V. Kulchar, M.D. (450 Sutter Street, San Francisco).—Doctor Epstein's paper is certainly most timely, as the place of mapharsen in the therapeutic armamentarium of syphilis is by no means as yet determined. Mapharsen has been used during the past two years in the syphilis clinic at Stanford in the treatment of early syphilis. Not feeling justified in relying upon a single drug, particularly one whose therapeutic efficiency was not established, mapharsen was used in combination with bismuth. Recently Dr. C. W. Barnett and I have surveyed our cases and found that the rate of involution of the primary and secondary lesions was slightly less than that commonly observed following neoarsphenamin. The rate of serologic reversal is, however, somewhat slower with mapharsen than with arsphenamin, and the percentage of central nervous system involvement following the treatment of early syphilis with mapharsen was at least equal to that observed with other arsenicals. The incidence of reactions following 1,270 injections of mapharsen was compared with that observed following an identical number of injections of neoarsphenamin. While pruritus, skin eruptions, and immediate reactions, including nitritoid, were slightly more frequent with neoarsphenamin, all other types of reaction, particularly nausea, vomiting, diarrhea and headache, were more common following mapharsen. Nearly one per cent of the injections was followed by venous thrombosis, often severe and extensive, which sometimes made it necessary to discontinue the use of the drug. The attempt to substitute mapharsen for neoarsphenamin in a patient who previously had had an arsphenamin dermatitis was followed by a recurrence of the dermatitis. In a few instances, however, the mapharsen could be substituted for neoarsphenamin in patients experiencing severe nitritoid reactions.

In our opinion mapharsen has not been clinically evaluated over a sufficiently lengthy period of time to advocate its general use in the treatment of syphilis.

⁂

Ernest H. Falconer, M.D. (384 Post Street, San Francisco).—My interest in this clinical study of mapharsen is confined to the study of its effects on the blood and blood-forming organs. This work was carried out in the hematology clinic at the University of California Medical School, and the results are embodied in a paper which will appear in the near future. In connection with the statement of the authors that mapharsen may be substituted when a patient is sensitive to arsphenamin or neoarsphenamin, this point was well brought out in studies which we made on two patients very sensitive to neoarsphenamin; purpura hemorrhagica having occurred three times (once in each case experimentally) following small amounts of neoarsphenamin. In both of these patients, repeated doses of mapharsen produced no reaction and no untoward effects. One patient in the mapharsen series developed a partial marrow aplasia with suppression of marrow function after .26 grams of mapharsen. This patient had an initial blood count of: hemoglobin, 75 per cent; red blood cells, 4,470,000; white blood cells, 5,800; platelets, 200,000.

Our experience has taught us that a syphilitic patient having the degree of anemia shown above, with a depression of the white cells, should not receive arsphenamins of any type until the anemia is corrected. An exception to this rule would be where one had reason to suspect the anemia as being due to syphilis itself. Such instances are probably rare. In our studies no instances of purpura hemorrhagica due to mapharsen were seen, but it may occur in the future after more widespread use of this drug.

⁂

Howard Morrow, M. D. (384 Post Street, San Francisco).—The report on mapharsen by Miller, Epstein, and Simpson has been so complete that there is little to add. At a recent meeting of the American Dermatological Association the subject was thoroughly discussed, and the reports concur with experiences published in this article. At the University of California clinic over 13,000 injections have been given in the past two years, and the results have been satisfactory. The fact that mapharsen can at times be used where neoarsphenamin is not tolerated makes it a very valuable addition to our list of antisyphilitic remedies.

⁂

Hiram E. Miller, M. D. (Closing).—The discussion on this paper has emphasized many of the important points in regard to mapharsen. One of Doctor Kulchar's findings, however, seems to be at variance with those of other observers. It is difficult to explain his twelve cases of venous thrombosis in 1,270 injections. We observed none in over 13,000 injections, and Gruhzit recently reports on 75,589 injections of mapharsen in which only two cases were noted.

Most observers agree that the reactions following the use of mapharsen in properly adjusted doses are less severe than those after the arsphenamins. Mapharsen is considered to be a safe and useful drug. We do not, at the present time, recommend that it be used in preference to the arsphenamins. Its exact place in the treatment of syphilis can only be determined by further study and observation.

PORTAL THROMBOSIS*

By Edward C. Pallette, M.D.
Los Angeles

Discussion *by Charles A. Noble, Jr., M. D., San Francisco; Arthur S. Granger, M. D., Los Angeles; George H. Houck, M. D., Los Angeles.*

Thrombosis of the portal venous system, either of the portal vein itself or of one or more of its branches or radicals, although a rather rare condition, must be regarded as far from a medical or pathological curiosity. One seldom sees this diagnosis on the hospital chart; it is considerably more common, however, in the autopsy protocol. It is with a feeling that the clinical picture of portal thrombosis goes far too often unrecognized that this paper was attempted.

The first adequate description of the signs and symptoms of this condition was made by Langdon-Brown in 1901.[1] Unfortunately he,[2] as well as several later writers, failed to distinguish clearly the difference between the two main types of portal thrombosis, *i. e.*, that associated with infection or suppuration, instances of which type we have all seen not too infrequently, and, secondly, that developing blandly or aseptically. Since the two have actually entirely different signs and symptoms, a different pathological physiology, a different etiology, it is important first to discuss these differences.

INCIDENCE OF PORTAL VEIN DISEASES

In a recent report from the staff meetings of the Mayo Clinic, 127 cases of diseases of the portal vein were reviewed.[6] Of these, seventy-four were of the aseptic type. The 1921 Johns Hopkins Bulletin contains a report of twenty-one cases of portal thrombosis in 5,050 autopsies.[3] An older German report gives sixty-eight cases in about 25,000 autopsies. I herein report eight cases occurring during the past four years at the Los Angeles County General Hospital out of a total of 5,600 autopsies. The frequency of occurrence of bland portal thrombosis, then, appears to vary between 0.1 and 0.2 of 1 per cent of all cases coming to autopsy. Suppurative portal thrombosis, as we have mentioned, is much more frequently seen at autopsy; and since it is merely a part of a septic process also shared by the liver and other organs, it is, of course, often recognized and diagnosed clinically. Bland portal thrombosis on the contrary, is very rarely diagnosed clinically[5] and, if one may judge from certain autopsy protocols read in connection with this condition, not always recognized as the essential pathology present at autopsy. This is undoubtedly because the terminal lesions present, such as gangrene of the intestine with diffuse peritonitis, frequently obscure the picture of the original thrombosis.

SEPTIC OR SUPPURATIVE PORTAL THROMBOSIS

Also commonly called portal pyemia, or suppurative pylethrombosis. This type is not uncommonly seen, and before the days of early operation for appendicitis, was even more frequent. It is not difficult to comprehend how infection from a neglected appendiceal gangrene or abscess can enter the terminal mesenteric radicals of the portal vein. (It is rather more difficult to understand why this does not occur more frequently than it does.) Then, infected emboli are formed which ascend through the mesenteric veins, a septic pylephlebitis results in the portal vein and multiple abscesses form in the liver. The picture is one of sepsis throughout, and of course may result from infected or suppurating lesions of any organ discharging venous blood into the portal circulation. In this connection it is well not to overlook the umbilical vein (obliterated), the esophageal and the hemorrhoidal veins, as cases have been reported following umbilical infections in infants,[4] and in adults associated with posterior mediastinitis and perirectal infections.

---

* Read before the semi-annual meeting of the Southern California Medical Society at Los Angeles, November, 1935.

To distinguish the course of suppurative thrombosis of the portal vein from hepatic abscess or suppurative cholangitis is often impossible, but in the presence of signs such a condition, associated with a septic focus in any region drained by the radicals of the portal system, septic thrombi in the portal vein or its mesenteric branches must be considered as being very possibly present. The picture differs from that seen in bland thrombosis, in that obstruction to the venous flow rarely occurs because of the soft friable type of the septic thrombus, and as a result ascites is exceptional.

ASEPTIC OR BLAND PORTAL THROMBOSIS

In referring to this type, Dr. William H. Welch speaks of occlusion of the portal vein as "a well characterized, although usually undiagnosed affection." Unfortunately, although some thirty-odd years have elapsed, we must still agree with his statement. In spite of a characteristic and clear-cut symptom complex based on a definite pathological physiology, this condition remains "usually undiagnosed."

By bland portal thrombosis we refer to that condition in which the lumen of either the main stem or the larger branches of the portal vein become filled with an uninfected thrombus, resulting in occlusion of that vein. The etiology, of course, varies greatly, but the essential etiology is that of thrombosis formation in general, and certain factors initiating this thrombus formation may be classed as:

1. Extrinsic.
2. Intrinsic.
3. Mechanical.
4. Chemical or toxic.

Under the heading of extrinsic causes, we may include pressure upon the vein by abdominal tumor, invasion of the vein by malignant growths, and pressure by impacted gall-stones or enlarged lymph nodes. Under intrinsic factors we speak of areas of venous sclerosis, inflammation and roughening of the intima of the vein. Under mechanical factors we mention slowed circulation of the blood due to cirrhosis of the liver (the most common lesion associated with bland portal thrombosis [3, 6]), chronic hepatitis and cardiac decompensation. Chemical factors are unproven, but it is well here to recall that portal blood may contain products from the digestive tract which have not yet become detoxified. I wish also to refer to my Case No. 1, in which the acute portal thrombosis apparently followed the ingestion of relatively large amounts of alcoholic beverage, and to say that Storch of New Orleans is allegedly reporting five cases of venous mesenteric thrombosis following acute alcoholism.[7]

The occlusion of the vein, then, regardless of the etiology, is responsible for the rather characteristic symptom complex to be described. The blood flow in the portal circulation is obstructed by the formed thrombus. It has been noted many times experimentally in dogs that, if the main trunk of the portal vein is ligated, the animal dies within two to three hours in a condition called "splanchnic shock." This has never been thoroughly explained, but it is apparent that the sudden alteration in blood flow in the splanchnic area produces an untoward stimulus to the abdominal sympathetic system which simulates fatal surgical shock. However, if the ligation is incomplete or done in stages so that the occlusion is not sudden, the animal does not die, but goes on to demonstrate a similar clinical picture to that seen in man in the presence of portal vein occlusion by thrombus. The portal circulation to the liver is slowly reëstablished by the development of a collateral circulation, which utilizes the obliterated umbilical and periumbilical veins, the falciform ligament, and the gastro-hepatic omentum particularly. In Case No. 1, reported later, this collateral circulation was very apparent at the time of the second laparotomy, one year following the acute portal thrombosis. It is so marked in the gastro-hepatic omentum that it has been likened, particularly in the German literature, to a cavernous hemangioma. It should be pointed out here that the collateral circulation in portal vein occlusion differs from that seen in pure cirrhosis of the liver, in that in the latter the circulation tends to be reëstablished in a hepatofugal direction, *i. e.*, away from the damaged liver into the peripheral circulation; whereas in portal vein thrombosis the collateral circulation is hepatopedal or around the occluded portion of the vein toward the still functioning liver.[5]

Thrombosis in a vein, of course, must necessarily occur suddenly. The amount and character of the pathological physiology produced must therefore vary only with the location of the occluding thrombus and its longitudinal extent. Unfortunately, it has been found that the primary thrombosis most commonly appears in the main trunk of the portal vein just as it enters the liver. As the forward motion of the blood is stopped, the thrombus propagates itself distally to include the large branches of the portal vein, namely the superior mesenteric and splenic veins. If this process does not occur too rapidly the collateral circulation, as above mentioned, may be sufficient to prevent fatal shock, but in the meantime a very dramatic and interesting clinical picture develops.

Probably as a result of venous back pressure, there is an onset of acute upper abdominal pain, sometimes colicky in nature, located in right upper quadrant and closely simulating gall-stone colic. Evidence of shock immediately appears, the degree of which depends, as we have said, upon the extent of the propagation of thrombus and the amount of the portal system involved. The pulse becomes rapid, weak, and thready, the blood pressure drops rapidly, and the temperature is subnormal. Within a very short time (in Case No. 1 within three house of the onset) an acute ascites develops. This is in the nature of a transudate, and results from the extrusion of the fluid elements of the portal blood from increased intravenous pressure in the obstructed portal circulation. The fluid then is clear yellow with a low specific gravity. This is only necessarily true in the early hours following the onset, however, as we shall see that later intestinal gangrene and ileus may change the character of the fluid. As the progress is observed the picture becomes more and more suggestive of an abdominal catastrophy. A marked leukocytosis is found. Cramp-like pains throughout the abdomen are followed by a blood-tinged diarrhea. Nausea and vomiting appear, the latter perhaps also containing blood. The bloody diarrhea is, of course, dependent upon the extension of the thrombus to involve the radicals of the superior mesenteric vein, producing a venous mesenteric thrombosis, ileus and, in many cases, intestinal gangrene and peritonitis. Blood in the vomitus is dependent upon the thrombus involving the splenic vein, which exhibits collateral circulation via the vasa breva. Death is the usual outcome in an acute portal thrombosis of any great extent, and may occur early as a result of shock, or later as a result of ileus, or intestinal gangrene with peritonitis.

It is, of course, true, however, that a goodly percentage of these individuals exhibiting thrombosis of the portal vein do not have as severe an attack as above outlined. This is because, as we have said, the process is less extensive in its involvement, and progresses slowly enough to permit adequate development of a collateral venous circulation. As one reviews the histories of individuals seen at the autopsy tables showing unmistakably ancient thrombotic changes in the portal vein and perhaps more recent thrombi in one or more of its branches or even in portions of the collateral circulation, one often finds that they have had one or more attacks of upper abdominal colic associated with transient ascites and often diarrhea. This type may be classed as a chronic thrombosis, and this is literally true in that from time to time further thromboses occur and the individual exhibits "critical episodes," or recurrent mild attacks of acute thrombosis, before succumbing, perhaps several years later, to incidental terminal sequellae which we shall now mention.

As we have said, the thrombosis tends to recur in individuals affected with this condition. Death may result in a spontaneous acute exacerbation from shock, ileus or peritonitis, or, as reported in several cases in the literature,[4, 6] it may follow splenectomy for a splenomegaly which quite constantly results from the thrombosis of the splenic vein. This splenomegaly may become quite marked and interestingly, is frequently associated with an anemia also quite marked. In these cases a diagnosis of primary splenic anemia or Banti's disease is made, and if a surgical cure is attempted, a further propagation of the thrombus into the mesenteric veins results in infarction of the intestine and death. We will not discuss here the varying etiology of splenic anemias, of which primary thrombosis of the splenic vein is one; but it would not seem amiss to suggest that, in cases where splenectomy is contemplated in treatment of Banti's disease, the history should be carefully examined for "critical episodes" suggestive of chronic portal thrombosis. Should such be the case, splenectomy must be considered as a hazardous venture.

TREATMENT

Unfortunately there is no treatment of any essential value in this condition. In acute cases the usual procedures for the treatment of shock, ileus, etc., are of course instituted. In my own case (No. 1), I felt that perhaps the repeated injections of intraspinal novocain given in the hope of relieving the marked ileus present was of considerable value, and perhaps definitely influenced the outcome toward the side of recovery. The basis for this opinion is that in relieving the critical distension of involved gut, the already embarrassed circulation to that loop is relieved. The huge ascites can be controlled by paracentesis. In the chronic cases, instructions should be given as to the avoidance of all alcoholic beverages, or any drug toxic in any way to the liver.

SUMMARY

Thrombosis of the portal venous system has been discussed from the standpoint of etiology, symptomatology, frequency, pathological physiology, and treatment. It is suggested that the condition is too infrequently recognized as a clinical entity. It is pointed out that the acute condition may closely simulate an abdominal emergency, and that in the chronic form the associated splenomegaly should not be regarded as successfully amenable to surgical treatment. One personal case and eight case histories of portal thrombosis from the Los Angeles County General Hospital are reported.

REPORT OF CASES

CASE 1.—H. A., female, white, divorced, 30 years, seen at 6 p. m., January 25, 1934. Admitted 9 p. m., St. Vincent's Hospital.

Personal History.—Has always been well. No operations. Drinks considerably—particularly during Christmas holidays—three weeks ago.

Came home from work as stenographer at 6 p. m. Felt tired and nauseated. Began to have colicy pain in epigastrium and vomited. When seen at 6:30 p. m., was lying doubled up with epigastric pain. Pulse rapid and weak. Perspiring and somewhat pale. Tenderness and spasm in right upper quadrant. Lower abdomen soft and flat. Sent to hospital, where seen again at 9 p. m. Patient then in complete shock. Pulse and blood pressure imperceptible. Air hunger. Abdomen now found to contain much fluid. Pelvic examination negative. White blood count 17,000.

Patient treated for shock. Thought to have positive ruptured ectopic pregnancy. Transfused and operated next morning, when condition slightly improved.

At operation, abdomen found filled with clear yellow fluid, two liters. Pelvis and all other organs found negative, except for thickened thrombosed portal vein. Liver showed considerable evidence of a chronic hepatitis. Abdomen closed.

Patient relieved immediately following operation and transfusion. On third day abdomen again distended with fluid and in addition marked ileus developed. Vomited several times and vomitus contained clots of blood. Ileus apparently of the paralytic type and treated with Levine tube. Connell suction and Harris drip. Ascitic fluid leaked continuously from wound. Ileus very marked and patient very uncoöperative. Used 100 milligrams novocain crystals as spinal anesthesia in treatment of ileus. Patient somewhat relieved. Patient transfused again on the eleventh day. On thirteenth day abdomen reopened, at suggestion of consultant. One hundred and fifty milligrams novocain crystals used as spinal anesthetic. More clear yellow fluid obtained. Evidence of rather marked ileus, but no gangrene or peritonitis. Following this operative procedure, patient again vomited blood-tinged material. Ileus persisted for some time, gradually subsiding in approximately three weeks. Ascitic fluid remained in abdomen, also gradually subsiding. Discharged in fair condition on March 10, 1934. Patient continued to have abdominal distension and recurrences of intermittent ascitis, both of which gradually subsided over a period of three to four months. General condition good.

Returned to hospital January 18, 1935, for repair of incisional hernia and exploratory. White blood count was still 15,000, polymorphonuclears 64 per cent. At operation, under spinal anesthesia, a spontaneous omentopexy was found and numerous greatly dilated veins were present in the gastrohepatic omentum. The portal vein was palpated as a firm cord very much resembling a rosary.

Other thrombi were seen in the omentum and one removed for examination. This revealed a bland organizing thrombus. The liver was as at previous operation. The spleen was considerably enlarged to palpation. The hernial defect was repaired and patient made an uneventful recovery. Two months later the spleen was found palpable almost to the umbilicus. Recurrent attacks of upper abdominal pain with intermittent ascites have occurred. Otherwise patient pretty well. No anemia associated with splenomegaly.

* * *

Case 2.—Patient No. 311-782, age 31, male, Malay, cook. Admitted October 1, 1933. Died November 16, 1933. Vomited blood (one day). Bloody stools (one day). Pain in epigastrium (two weeks). Diagnosed bleeding peptic ulcer, but x-rays not confirmatory. Ascites present on October 14. Diagnosed Banti's disease and splenectomy performed November 10. On November 15, white blood count 23,800. Died with distended abdomen. Autopsy: Stomach filled with bloody fluid. The portal, splenic and superior mesenteric veins filled with recent bland thrombus. Gangrene of intestine. Incidental: Primary carcinomia (hepatoma) of liver.

* * *

Case 3.—Patient No. 186-733, white, male, age 45. Admitted November 7, 1931. Died November 24, 1931. Complaint: Pain in right upper abdomen, shortness of breath, enlargement of liver. Treated for cardiac decompensation. On November 22, sudden onset of severe abdomenal cramps, unrelieved by morphin. Died two days later with distended abdomen. Autopsy showed bland thrombosis of superior mesenteric vein, with gangrene of upper small intestine. Abdomen filled with bloody fluid. Evidence for hypertensive heart disease.

* * *

Case 4.—Patient No. 172-160, white, male, age 74. Cement worker. Entered hospital February 11, 1932. Died February 19, 1932. Complaints: Pain in abdomen, mental confusion. Admitting room diagnosis: Abdominal pathology. Vomited dark fluid. Became comatose. Abdomen distended and tense. Autopsy showed acute bland thrombosis of all mesenteric veins to small intestine with gangrene of intestine. Abdomen filled with bloody fluid. Evidence of arteriosclerotic heart disease.

* * *

Case 5.—Patient No. 201-819, white, female, age 37. Admitted July 19, 1933. Died July 25, 1933. Patient operated July 21, and cholecystectomy for "strawberry" gall-bladder performed. Death three days later with hyperpyrexia. Autopsy showed operative ligation of right portal vein and right hepatic artery with infarction of right lobe of liver.

* * *

Case 6.—Patient No. 194-698, white, male, age 5 months. Admitted March 14, 1932. Died March 14, 1932. Clinical diagnosis on admission: Bronchopneumonia. Autopsy showed bilateral staphylococcic bronchopneumonia, plus thrombosis of superior mesenteric vein.

Case 7.—Patient No. 179-882, white, male, missionary, age 52. Admitted September 24, 1931. Died September 25, 1931. Distended, painful abdomen containing ascitic fluid on admission. Electrocardiogram indicated coronary disease. Vomited bloody material. Autopsy showed marked portal cirrhosis with thrombosis of mesenteric veins and gangrene of intestines.

* * *

Case 8.—Patient No. 98-697, white, male, age 60. Admitted October 20, 1931. Died October 23, 1931. Complaint: Pain in abdomen and vomiting; loss of weight. Found to have carcinoma of stomach and died following a partial resection. Thought to have died of hemorrhage. Autopsy showed carcinoma of stomach with metastasis to liver, and acute bland thrombosis of superior mesenteric veins.

* * *

Case 9.—Patient No. 113-643, white, male, age 59. Admitted December 26, 1930. Died January 1, 1931. History of previous attacks of upper abdominal pain associated with hematemesis. Clinical diagnosis: Cirrhosis with bleeding esophageal varices. Continued to vomit blood. Transfused several times. Died of hemorrhage. Autopsy showed Caput Medusa, portal cirrhosis, thrombosis of superior mesenteric, splenic and short gastric veins. Gastric varices.

DISCUSSION

Charles A. Noble, Jr., M. D. (384 Post Street, San Francisco).—To listen to this interesting presentation of portal thrombosis has been a privilege for which I am deeply grateful. Doctor Pallette has covered his rare subject in a masterly way. For me, a mere internist, to comment on its surgical phases would perhaps be audacious, but it might be of interest to review the connection between portal thrombosis and splenic anemia, or Banti's syndrome.

In the first place, let me attest the rarity of the diagnosis, portal thrombosis, in our hospitals. Out of 25,000 admissions at the University of California Hospital, portal thrombosis of the bland form was diagnosed four times—three times only at autopsy; and in each case it was but a terminal episode in a neoplastic disease. During a fifteen-year period at the San Francisco Hospital, covering 145,000 admissions, bland thrombosis was diagnosed nine times, and proved in but seven. Of these seven patients, two died of neoplastic disease, two of tuberculosis, one of congestive heart failure, and one of a subacute bacterial endocarditis. In only one case was the diagnosis made antemortem as a primary episode leading to splenectomy and cured, at least temporarily.

These figures would imply that this is a rare condition. Rolleston, however, states that 3 per cent of patients with such a common disease as cirrhosis of the liver have portal thrombosis. The discrepancy probably lies in the fact that a diagnosis not kept in mind is going to be missed not only clinically, but at autopsy.

Just what is Banti's syndrome? In 1866 Greissinger described a group of symptoms including splenomegaly and anemia, to which he gave the name "splenic anemia." In 1884 Banti added a group of patients that he felt were entirely distinct from those with splenic anemia. The characteristic course which he described was divided into three stages, the first consisting merely of painless splenomegaly, anemia and leukopenia, with a normal liver, lasting anywhere from three to twelve years; the second of beginning hepatomegaly, with urobilinuria, lasting twelve to eighteen months; the third, and a quickly terminal phase, indistinguishable from cirrhosis of the liver, of ascites with evidence of portal block. Moreover, the important feature to Banti was that there should be no evidence of syphilis, malaria or, for that matter, any other known reason for this strange syndrome. The splenic pathology was a characteristic fibrosis of reticulum and Malpighian follicles—degeneration, and frequently thrombosis of the splenic vein.

These delineating characteristics were soon forgotten, and splenic anemia and Banti's disease became to some, such as Osler, merely one and the same disease; those cases progressing to the third or last stage, with hepatic damage, being allowed the eponymic title of Banti's disease. It was Osler, too, not Banti, who pointed out the frequency of early and oft-repeated gastro-intestinal hemorrhage, occurring long before there is any evidence of liver damage.

Splenic anemia as a disease was a real medical Poland, from which bits of territory have continually been removed. These removals include cases where factors such as pernicious anemia, hemolytic anemia, Von Jaksch's anemia, lymhoblastoma, and the leukemias, the Gaucher group, syphilis, kala-azar, and malaria, have been identified as playing an etiologic rôle. What is left?

Undoubtedly there is a group of cases of unknown etiology with some or all of the symptoms and signs described above by Banti. Perhaps many would not progress to have cirrhosis of the liver. In some of them, but not all, portal or particularly splenic vein thrombosis is found on careful search at autopsy, but is this thrombosis secondary to the splenic changes, or does the splenomegaly succeed the venous clot? It is probable that both sequences take place. There are cases on record of splenic vein thrombosis with pain, splenomegaly, fever, and leukocytosis, which later develop gastric hemorrhages, anemia, and leukopenia. Some pathologists claim that the splenic pathologic picture is different from that described by Banti. Others, however, claim that the pictures are identical, and that even in certain patients with primary cirrhosis of the liver, the spleen may simulate the Banti spleen. Until more is known about the cause of the splenomegaly, and of these pathologic changes, confusion will continue to reign.

However, in splenic anemia it is important to try to distinguish those cases where splenic vein thrombosis has taken place, because those are perhaps the ones where splenectomy is contraindicated. Perhaps the history of pain, fever, rapid splenomegaly, or development of collateral circulation without evidence of liver damage are the most helpful symptom signs in suggesting past thrombosis. Rarely do any of these symptoms occur early in the group described by Banti. Should glycosuria occur, it would suggest interference also with pancreatic circulation. The rapid development of ascites is not a valid differential point, as this phenomenon sometimes occurs in cirrhosis of the liver.

Splenectomy, as you know, has long been advocated for patients with splenic anemia. More recently splenic artery ligation has been successfully reported. Cures are often dramatic, but portal thrombosis is a frequent complication, and possibly patients with a previous thrombosis are the ones in which this is most apt to occur. Evans, in England, has confirmed the experience of Rosenthal that patients in whom the preoperative platelet count was below normal did better postoperatively than the group whose platelets were normal or slightly increased in number. In both groups the platelet counts rose to high levels postoperatively, but in those with normal counts preoperatively the platelets stayed up, and in this group thrombosis may occur more often. Perhaps experience will show this test to be of value.

In conclusion, let me reiterate that splenic anemia is merely a broader group, from which Banti has separated cases whose etiology could not be determined. Splenic vein thrombosis can in time produce a similar, if not identical, syndrome. Only more attention clinically and pathologically to the portal venous tree will help elucidate this problem. May I plead for such attention?

Arthur S. Granger, M.D. (2007 Wilshire Boulevard, Los Angeles).—The acute type of bland portal thrombosis, such as occurred in the case reported by Doctor Pallette is, fortunately, but rarely seen. The difficulties in diagnosis of such a condition are apparent, but the sudden onset of ascites is certainly suggestive of pathology of this type. In the more slowly developing cases, where the occlusion of the portal vein is gradual, sufficient time usually elapses for the development of collateral circulation, and here the picture is that of a chronic splenic anemia, with splenomegaly, anemia, occasionally leukopenia and a tendency for hemorrhages from the stomach and intestines. Extreme caution should be exercised in the treatment of these chronic forms, especially if splenectomy is contemplated, and such a procedure should not, of course, be undertaken if there be any sign of thrombosis in the portal system.

*

George H. Houck, M. D. (2007 Wilshire Boulevard, Los Angeles).—Improvement in diagnosis not infrequently depends upon greater knowledge of the local lesions which may obstruct blood vessels. In the arteriosclerotic syndrome one expects thromboses of cerebral or coronary arteries, and in certain chronic abdominal diseases one may look forward to obstructive lesions within the veins of the portal system. Thus, "bland" portal thrombosis may occur in relation with cirrhosis, neoplastic disease, hepatic syphilis, and other disorders. Doctor Pallette emphasizes these sequences, and calls to our attention the symptoms which may be expected. This symptom picture has been, and continues to be, one which confuses the physician. Acute ascites, however, should bring to mind the possibility of portal thrombosis, and it will be useful to include the same condition in the differential diagnosis of the splenic anemias.

OBSTETRICAL ANESTHESIA*

By La Verne Wright, M.D.
San Francisco

Discussion *by Edward N. Ewer, M. D., Oakland; Caroline B. Palmer, M. D., San Francisco; H. A. Stephenson, M. D., San Francisco.*

WITH the ever-increasing demand of the modern woman for painless childbirth, obstetricians and anesthetists have been increasingly diligent in the search for an ideal analgesic that will meet the demand.

At present we have none: each case has different needs and different reactions, requiring oftentimes the closest coöperation between the patient, obstetrician, and anesthetist, all working for the greatest possible relief.

ETHER AND CHLOROFORM

Since the discovery of ether by Long in 1842 and chloroform by Simpson in 1847, many drugs and combinations of drugs have been tried and discarded. At the present time chloroform is but little used, unless it be in rural districts, for though efficient in relieving the mother's pain, it was found to have injurious effects on the child; and while ether is safer for both mother and child, the present trend is also away from it. Both were used extensively for many years.

SCOPOLAMIN AND MORPHIN

We then come to the days of twilight sleep, introduced in 1902 by Steinbrickel of Germany and reaching the height of its popularity about

---

* Read before the Anesthesiology Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

1915. The reaction of many patients to the routine administration of scopolamin and morphin caused worry, because of the greatly depressed respiration and blood pressure; and given in smaller doses it often left the patient unmanageable, without the desired results. In either instance many babies were narcotized and some could not be resuscitated. Hence, it has been practically discarded.

MORPHIN AND ETHER

In 1923, Gwathmey of New York introduced a method of analgesia employing both morphin and ether. It then was and still is considered very valuable by many leading obstetricians, especially in primiparae with long, slow labors. It consists of a preliminary dose of 1/6 to 1/4 grain of morphin, administered in the first stage, usually when the cervix is about half-dilated. Gwathmey found the morphin more effective when combined with two cubic centimeters of chemically pure magnesium sulphate, followed in about one-half to one hour by a colonic instillation, consisting of quinin 10 grains, alcohol 2 drams, ether 2½ ounces in 4 ounces of olive oil, to be very slightly warmed and instilled slowly after first cleansing the rectum with an enema. Care should be taken to get this mixture high up in the bowel above the presenting part. The patient usually enters into a fairly deep sleep, arousing only with pains. The effect of this usually lasts about three hours, at the end of which most patients can have gas and oxygen started. This method is considered safe for both mother and child, unless contraindicated by a history of diabetes, colitis, respiratory disease, or chronic kidney disease in the mother. Other toxemias, cardiac cases or malpositions do not constitute contraindications, and it can be safely used in the home. If labor is prolonged and analgesia is not of sufficient duration, it may be repeated after four hours, omitting or reducing to a minimum the morphin injection if delivery is probable in the following four hours. In a small percentage of cases there is lack of coöperation, but of no serious character, and in all cases the perineal muscles are well relaxed. After delivery, it is well to empty the bowel by passing a rectal tube and then injecting three to four ounces of oil, to be retained.

AVERTIN

Tribromethanol or avertin was developed in Germany in 1927, and used quite extensively in obstetrics in Europe, but as it is contraindicated in diseases of the kidneys, liver and colon, and in hypothyroid cases, its use in this country in obstetrics is mostly confined to selected cases, and then in doses that require the addition of nitrous oxid and oxygen in the third stage and for repair. It is given rectally between pains after the head is below the brim and the cervix is well dilated. The advised dose is limited to 60 milligrams per kilo body weight, preceded one-half to one hour by one-sixth grain of morphin hypodermically. It is said to have been used with good results in eclampsia in larger doses, 80 to 100 milligrams per kilo. The convulsions finally cease after becoming less severe and less frequent.

In the last three or four years the barbiturates have become increasingly popular, either as the principal hypnotic or as adjuvants to morphin and scopolamin. They are slowly eliminated, and their action as hypnotics is not only prompt but prolonged. In therapeutic doses they do not materially affect the respiration of the mother or the circulation of either mother or child, though some narcotized babies have been reported by DeLee when sodium amytal was used. Pentobarbital sodium is at present the most popular and most frequently used, the dose ranging from four to as much as seven and a half grains. In a large percentage of mothers there is a restlessness and lack of coöperation which require extra nursing supervision. In primiparae and slowly progressing multiparae, the time they are given depends more on the frequency and character of the pains than on the dilatation of the cervix. The restlessness seems less if the large initial dose of six to seven and a half grains followed by 1/150th to 1/200th of a grain of scopolamin *or* one-eighth to one-fourth grain of morphin. This may be repeated in smaller doses if labor is prolonged. It is contraindicated in known hepatic disease.

PARALDEHYD

Within the past year paraldehyd has again returned to the field of surgery, as well as obstetrics, as a hypnotic and sedative. It is commonly called the safest hypnotic, as no unfavorable effects on the circulation, respiration, blood pressure or metabolism have been recorded, and, barring the disagreeable odor, there is much in its favor. A few cases of hiccoughs, possibly one in twenty cases, have been noted, but of only short duration. Because of the very disagreeable odor and taste, it is best given by rectal injection in dosage of one cubic centimeter of paraldehyd to each eight and one-half pounds of body weight, with one and one-half cubic centimeters of benzyl alcohol. This is given rectally through a large catheter, after the bowel has been thoroughly cleansed with a soapsuds enema and the paraldehyd followed immediately by the instillation of one ounce of normal salt solution. As it is eliminated from the body largely through the lungs (very slightly through the kidneys and skin), the odor appears very quickly on the breath of the patient, though she is unconscious of it. In obstetrics the rectal injection is given when the patient begins to complain of her pains, followed in one-half to one hour by one-sixth grain of morphin hypodermically and after another hour, a second rectal injection of paraldehyd may be given if necessary. The patient is more coöperative than with pentobarbital and morphin, or scopolamin, and while the effect on the pain is less than with avertin, the margin of safety, which is the first consideration, is much greater and the expense to the patient much less. Paraldehyd may be observed on the infant's breath, but very few cases of infantile asphyxia have been observed or reported.

CYCLOPROPANE

Cyclopropane (C_3H_6), a hydrocarbon gas, developed in 1929 and 1930, is a powerful anesthetic and said not to impair the vasomotor centers nor reduce the blood pressure. Used with a large percentage of oxygen, at least 85 per cent, one or two inhalations will give complete relief from a labor pain. Wesley Bourne, recently reported its satisfactory use in thirty-four cases, while Griffith of Montreal has reported one hundred and forty cases. Personally, I have had no experience with it. Reports indicate that the margin of safety of nitrous oxid and oxygen as a supplementary anesthetic in the third stage is much greater than with cyclopropane. The same may be said of vinil ether and vinethene and evipal.

Spinal and sacral anesthesia have been used in selected cases in the second and third stages and, while no deleterious effects on the child have been reported, the contraindications and dangers are the same as in surgery.

DILAUDID HYDROCHLORID

In 1934, dilaudid hydrochlorid, the hydrochlorid of dihydromorphinone, was first used in very small doses, 1/32nd of a grain, in place of morphin for analgesia after labor is well established. It may be given with or without scopolamin, paraldehyd, barbiturates, or rectal ether-oil. Reports indicate that it acts quickly, uterine contractions are not decreased, nausea is less, and infantile narcosis is less than with morphin.

IN CONCLUSION

While the ideal anesthetic and analgesic have not been found, much good has resulted from the employment of the methods and drugs above outlined. If limited to one method alone, nitrous oxid and oxygen would give the best results to the largest number. The other methods can be used in conjunction with the gas and oxygen, but let us not forget that the use of such an anesthetic is not without its dangers. Obstetrical patients are usually not well prepared for anesthesia, as many women go into labor soon after eating and aspiration must be guarded against. Even with such warnings, the occasional death results. Such emergencies presented by obstetrics for both obstetrician and anesthetist can be matched by no other specialty or branch of medicine, and call for experience, coöperation and teamwork to obtain the best results.

When there is a laceration or an episiotomy to be repaired and no premedication has been given, many obstetricians routinely order an opiate as one-sixth to one-fourth of morphin, or one-third of pantopon, to be given as soon as the cord is tied, thus treating it from then on as a purely surgical case, and in many cases this makes the addition of ether unnecessary or at least reduces it to the minimum.

In spite of the cry being raised in the daily press and lay magazines by a few individuals, I believe women will continue to demand relief from the pains of childbirth. I do not believe damage to personality results from absence of suffering in childbirth, but quite the opposite. The use of safe analgesics takes away the fear of childbearing that all physicians are so familiar with; and since the lack of that fear will add to any prospective mother's personality and charm, let us continue the search!

3856 California Street.

DISCUSSION

Edward N. Ewer, M. D. (251 Moss Avenue, Oakland). Doctor Wright's evaluation of the available analgesic and anesthetic methods agrees closely, I think, with that of the conscientious obstetrician who is determined to give his patients the greatest degree of comfort compatible with safety.

Our first anesthetic was chloroform. It was pleasant and quick in its relief of pain, but had to be abandoned because of rare cases of dangerous liver damage and frequent cases of fetal anoxemia and postpartum hemorrhage.

Ether followed, and was safe enough but slow in action, and required a certain aptness in administration different from that required in the production of surgical anesthesia. With it the pain has to be anticipated a little. Too much ether stops the labor.

Gas without oxygen is quick, but, like chloroform, causes anoxemia in both mother and baby. With oxygen it is safe, but, like ether, more skill and attention are necessary to get the results desired.

When the hospital anesthetist arrives as the head is passing over the perineum, the inhalation agents are skillfully used and the relief is all that can be desired.

But our difficulties arise during a long first and part of the expulsive stage. Here is the field for the analgesics. Each of them in safe dosage is effective for three hours. As they must often be repeated two or three times, we must choose the ones attended with the fewest difficulties, discomforts, and dangers at these repetitions.

The two which seem best to fulfill these considerations at the present time are pentobarbital and peraldehyd, with an occasional sixth or eighth grain hypodermic of morphin if the patient becomes mentally disturbed and unmanageable.

We regret the loss of coöperation on the part of the patient. However, she is relieved of pain, cervix dilatation is not interfered with, and, after all, we can master inefficient expulsive efforts with a relatively harmless minor operation for delivery, after cervix dilatation and descent are accomplished.

The Gwathmey analgesia has served us fairly well and has been improved by the addition of paraldehyd.

It seems to me that paraldehyd alone, or following an initial small dose of pentobarbital, is likely to supplant the Gwathmey. It can be given with benzyl alcohol as often as necessary without trouble or danger.

All the other agents have disadvantages, as pointed out by Doctor Wright.

A procedure which we have found satisfactory at the Alameda County Hospital is as follows:

Three grains of pentobarbital are given early in labor. In two to four hours 15 cubic centimeters of paraldehyd with 1½ cubic centimeter of benzyl alcohol are instilled rectally, without oil. This is repeated when necessary. Gas and oxygen are given for the last of the second stage and for repair work.

With more use of the analgesics, many obstetricians note a decrease in major obstetric operations. The patient, more comfortable, will tolerate a longer labor, and relatives are less urgent in their demands for action.

This paper of Doctor Wright is not marred by overenthusiasm, and no questionable procedures are advised. It is safe, sane and yet encouraging, unlike some recent discussions of the subject.

⁂

Caroline B. Palmer, M.D. (2300 Webster Street, San Francisco).—This paper appeals to me as of special value, because it is confined strictly to the subject of anesthesia. Many papers are given at anesthetic meetings which report research work, or sometimes pseudoresearch, the deductions from which have no practical bearing on anesthesia.

I would like to stress the value and safety of nitrous oxid oxygen in obstetrics, and to emphasize the point which the writer has brought out of the necessity of cooperation between obstetrician and anesthetist in order to obtain the best results.

The writer has implied the necessity of a skilled anesthetist in obstetrical analgesia and anesthesia. This point, also, cannot be stressed too greatly, as at any time in the course of delivery conditions may arise that endanger two lives, and the anesthetist should not be forced to ask the help of the obstetrician. Most experienced anesthetists have known of tragic results due to the rather prevalent idea that almost anyone can give an obstetrical anesthetic.

⁂

H. A. Stephenson, M.D. (490 Post Street, San Francisco).—Doctor Wright has covered the subject well and understandingly. I have had no experience with avertin and cyclopropane. Of the others, I feel that, in selected cases, paraldehyd, followed by morphin, nitrous oxid and oxygen have given best results. The analgesia is usually quite satisfactory, and the amount and duration of anesthetic required in the second stage are reduced considerably. The recovery of such patients seems to me to be somewhat more rapid than in patients not receiving this combination of drugs. No ill effects on mother or baby have been observed after its use.

Doctor Wright mentions briefly the barbiturates. These have received great attention lately, and have been extensively employed. My experience with them leads me to the conclusion that they possess no advantage over the paraldehyd.

I wish to strongly emphasize the point brought out regarding the necessity of good teamwork and coöperation on the part of anesthetist and obstetrician.

TESTS FOR VASOMOTOR CONTROL

By LeRoy K. Gay, M.D.
and
J. T. Hardesty, M.D.
San Francisco

An abundance of literature has been accumulating on the subject of peripheral circulatory disorders. Numerous measures, complicated for the most part, have been advocated as a means of distinguishing between vasomotor spasm and obliterative arterial disease. To the general reader, the data offered is often confusing, or its scope of application narrowed to a few clinics specializing in the study of such disturbances. There are, however, several simple tests requiring no elaborate apparatus which may be utilized in the office.

The basic principle of the majority of the procedures, to be briefly described below, is to produce, directly or reflexly, a state of vasodilatation of the peripheral vessels. An important prerequisite in every instance is that the environmental temperature, where the test is being conducted, be in the range of 18 Centigrade to 22 Centigrade, in order to obtain a preliminary low-basal level as a measure of comparison after vasodilatation.

Thrombo-angiitis obliterans and Raynaud's syndrome are the two peripheral circulatory diseases of chief concern, due to the relatively high incidence of both afflictions; the difficulties encountered in arriving at a definite diagnosis; and the rapid strides made by the neurosurgeons, in recent years, to alleviate the pain and limitation of activity, particularly in the case of the former. Sympathectomy is usually unsuccessful in Raynaud's phenomenon, because the disturbance is due to a local fault of the vessels, which, while not definitely known, is regarded as a functional one, an overaction to the cold stimulus.

INDIRECT OBSERVATIONS OF THE PERIPHERAL VESSELS

1. *Peripheral Pulse.*—In addition to the radial pulse which is usually palpated, the dorsalis pedis, posterior tibial, popliteal and femoral arteries are easily accessible. Absence of pulsations in one of these principal vessels is significant. It is well to remember that the dorsalis pedis is absent in four per cent of cases, and that in another eight per cent the artery is in a lateral position. The pedal pulses are frequently found to be absent in older male patients, who usually have no complaints. The slow gradual occlusion of the main vessels has permitted the development of an adequate collateral circulation.

2. *Postural Color Changes.*—Pallor on elevation of the part accentuated by rapid dorsal and ventral flexion, and rubor in the dependent position are signs of diminished blood flow. At a certain level, usually below the horizontal position, the pallor changes to the normal skin color without showing the reddish hue of capillary stagnation.

3. *Blood Pressure Determination.*—The ordinary sphygmomanometer can be readily employed to measure the difference in blood pressure on the two sides, both upper and lower extremities. The patient should be in the supine position and relaxed as much as possible.

4. *Cutaneous Histamin Reaction.*—See paper by Dr. Eric Ogden on this subject (Histamin and Adrenalin Tests).

5. *The Plethysmograph.*—Blood-volume changes in the digits or the extremities can be determined by the aid of this instrument. An airtight capsule to which is attached a finely-drawn pipette, containing a small amount of a colored indicator, is fitted snugly to the part to be examined. Photographic records are taken of the oscillations of the liquid indicator. The extent of excursion of the pulse is probably the result of the same factors which maintain blood pressure, in addition to the resistance of the soft tissues of the part in question. The deflection obtained is dependent upon the ability of the vessels to dilate with each heart beat and, in this sense, is a measure of vascular dilatation of the part. This pulse volume deviates sharply, in size and contour, in patients suffering from occlusive diseases of the arteries.

6. *Reactive Hyperemia.*—This phenomenon displays itself in a bright flush of the skin associated with an increased volume of the pulse on releasing the obstruction to the circulation. It was first intensively studied by Bier and has been further investigated by Lewis and Grant. Reactive hyperemia produces active dilatation of superficial terminal arterioles and outermost arteriolar plexuses, as well as deep vessels of an extremity. It is believed to be due to the accumulation of slowly diffusible products of metabolism in the extravascular spaces during the period of circulatory disturbance.

This test, therefore, can be employed to determine the patency of peripheral vessels in an extremity, under control conditions.

A blood pressure cuff is applied to the upper part of the extremity to be studied. The pressure in the cuff is raised abruptly to 300 or 350 millimeters of mercury. Time of occlusion varies from five seconds to fifteen minutes, average five minutes. The reaction is greater in a limb, the temperature of which has been raised to 30 to 35 Centigrade, but has no effect on its duration. Hyperemic flushing lasts from one-half to three-quarters as long as the occlusion is maintained. It reaches its height within twenty to thirty seconds and then fades away more gradually; the fraction is smaller when occlusions are very prolonged.

Visual observation, while simple, is quite inaccurate, since heat tends to produce reddening of the skin. Volumetric measurements using a water plethysmograph are more satisfactory and, in addition, the rate at which blood is entering the arm, under given condition, can be ascertained.

DIRECT OBSERVATIONS OF THE PERIPHERAL VESSELS

1. *Skin Temperature.*—The skin temperature of a given extremity depends upon the temperature and humidity of the examining room and body temperature. If these factors are fairly well controlled, room temperature 22 Centigrade, the patient resting and the oral temperature is normal, then thermal changes of the skin are chiefly dependent upon the blood flow. A flat-bulbed mercury skin thermometer is suitable for such determinations.

The value of skin temperature readings, obtained in this manner, is limited to : (1) a sudden drop in the temperature of one extremity indicates inadequate arterial flow; (2) marked differences between symmetrical areas on two extremities; and (3) a rise in temperature after employing various measures designed to relieve vessel spasm, which indicates a spastic element in the vascular occlusion.

2. *Tobacco-Smoking Test.*—Wright and Moffat found that surface temperature dropped markedly following the inhaling of cigarette smoke. This reduction in temperature is believed to be due to the absorption of minute quantities of nicotine. It is a manifestation of the response of the sympathetic nervous system to mild stimulation.

The subject was seated with his hands at the heart level, controlled room temperature and preliminary surface temperature readings taken. The cigarette was suspended by a reed before the patient who was permitted to smoke according to his usual custom. Temperature readings were recorded during and after the period of smoking. Cigarettes and denicotinized ones in addition to "filter paper" cigarettes were utilized in the experiment.

Each type of cigarette, except the "filter paper" cigarette, produced a drop in surface temperature as much as 10 to 15 Fahrenheit, the average being 5.3 Fahrenheit. The change in temperature may not occur with the smoking of every cigarette, but will be noted at some time during the course of a series of cigarettes smoked.

Lampson measured the rate of peripheral blood flow by accurately determining the rate of increase in the hand volume following occlusion of venous return at the wrist. The apparatus employed was a water plethysmograph. No smoking was permitted for three hours before the experiment.

The subject lay on his back, fully clothed and covered with a thin woolen blanket, with the right hand in the apparatus, under controlled conditions. The water-bath temperature varied between 30 to 33 Centigrade. The first half hour was devoted to determine the normal rate of blood flow; the patient then smoked, and records were taken during and after the period of smoking. The results were as follows: (1) inhaling of tobacco smoke—sudden drop in the rate of peripheral blood flow during the period of smoking, and at the end of forty minutes the flow was still partially depressed. Rise in blood pressure of 10 to 20 millimeters of mercury; pulse rate accelerated from six to twenty beats per minute; (2) noninhaling-vasoconstrictor response which lasted only fifteen minutes. Changes in heart rate and blood pressure were insignificant; (3) denicotinized cigarettes—no vasoconstrictor response. The inhalation of a second cigarette induced slight reduction in the rate of blood flow, which returned to normal in fifteen minutes. Pulse rate and blood pressure remained constant; (4) pipe-smoking showed moderate reduction in blood flow during the act of puffing. No change in heart rate or blood pressure. If smoke were inhaled, sudden vasoconstriction occurred; (5) cigar smoking—30 per cent reduction in blood flow; 75 per cent reduction after moderate inhaling.

Blood-flow rate of reduction was greatest immediately after smoking. The degree and duration of vasoconstriction could be correlated to the amount of nicotin absorbed. Inhaling of tobacco smoke at least halved the rate of peripheral blood flow and caused it to remain partially depressed for about an hour. If smoke is not inhaled, the vasoconstrictor response is almost as great, but the reaction persists for only fifteen minutes.

3. *Overcooling.*—This procedure is utilized in studying Reynaud's syndrome of the upper extremities. Since excessive cold induces an after-reaction in the skin, tending to dilate the arterioles, this test effectively determines the degree and extent of involvement of the vessels, and suggests an appropriate course of therapy, vessel reeducation.

The more affected digit of one hand and the corresponding digit of the other are immersed in cooled water, at or near 0 Centigrade for ten minutes. The digits are withdrawn, gently wiped dry, and skin temperature readings are taken at five-minute intervals. The height of reaction occurs in about twenty minutes and continues for an hour or more. The neighboring digits act as controls during the test. In mild cases of the disease, the reaction of warmth of the immersed fingers will be observed to spread to the immediately adjacent digits, but in the more advanced stages little or no reaction is noted, reddening of the skin indicating only mild vasodilatation.

4. *Cold Stimulation Test.*—Hines and Brown devised this procedure as a possible means of detecting a prehypertensive state in patients who later in life develop essential hypertension. In subjects with essential hypertension vasomotor centers react excessively to stimuli which in normal individuals produce a minimal response. If hyperreactability in this disease is due to a biologic constitutional defect, its existence should be demonstrable in early life. It is of indefinite value if therapeutic measures to control vasomotor irritability are to be instituted before actual signs of disease appear.

The subject is placed in a recumbent position for fifteen minutes or until the blood pressure has approximated the basal level. With the blood pressure cuff placed on one arm, the opposite hand is placed in cooled water (4 to 5 Centigrade) ; the blood pressure is taken at the end of thirty seconds and again at the end of sixty seconds. The hand is removed from the water and readings are taken every two minutes until the blood pressure returns to the initial basal level. The highest reading obtained is recorded as a measure of the response. Usually the blood pressure returns to the basal level in two minutes after removal of the hand from water. This reaction is independent of any significant changes in the pulse rate.

Results: (1) normal group-average response for blood pressure, 8.8 millimeters and 7.93 millimeters of mercury systolic and diastolic, respectively. Range varied from 5 to 15 millmeters and 5 to 12 millimeters of mercury systolic and diastolic, respectively; (2) hypertensive group—young adults included—average values for blood pressure 34.5 millimeters and 23.2 millimeters of mercury systolic and diastolic, respectively. The range varied from 20 to 90 millimeters and 15 to 65 millimeters of mercury systolic and diastolic, respectively. The basis for the reaction is regarded as being purely a neurogenic reflex response to cold.

5. *Immersion of Forearms in Warmed Water.* This method, suggested by Gibbon and Landis, produces reflex dilatation of vessels of the lower extremities.

Both forearms are immersed for twenty minutes in warmed water, maintained at a temperature of 43 to 45 Centigrade by means of an electric heating coil. Skin temperature readings are taken at regular intervals from the time of immersion. Temperature rise in the toes will be observed in about fifteen minutes, normal vasodilatation level (32 Centigrade) being reached in thirty minutes. In defective peripheral circulation a rise in skin temperature reaching or exceeding the normal vasodilatation level definitely excludes obliterative structural disease, demonstrating an adequate vascular bed to overcome the organic obstruction.

6. *Blanket Method of Coller and Maddock.*—The subject is covered with a light rubber sheet to the clavicular line and wrapped in three woolen blankets. With the high environmental temperature attained in this manner, the physical regulation of the body temperature results in maximal dilatation of the peripheral vessels.

Skin temperature readings are taken at the end of one hour. If the level of normal vasodilatation is not reached in this period, it is indicative of organic vascular occlusion.

7. *Induction of Artificial Fever.*—Lederle triple typhoid vaccine, five to twenty-five million killed organisms, injected intravenously. Mouth and skin temperature readings recorded every half hour over a period of three to five hours.

The following factors are thus obtained: (1) vasomotor index, the quotient of the rise in surface temperature divided by the rise in mouth temperature. A vasomotor index of two or more indicates an abnormal degree of vasoconstriction; (2) vasomotor range-rise in surface temperature of the affected digits from basal to maximum levels with fever. A high degree of vasoconstriction is considered to be present if this increase is 4 Centigrade or more; (3) maximum vasodilatation level—the highest temperature obtained in the affected digits. A level of 31.5 Centigrade or more indicates an adequate degree of vasodilatation of the digits in question.

In all of the foregoing factors, the rise in temperature of the mouth is deducted from the rise in surface temperature, so as to eliminate the actual increase in the temperature of the blood.

8. *The Oscillometer.*—Boulitte modification of the Paschon oscillometer. The apparatus consists of two overlapping distensible pouches, having a combined width of 15 centimeters, enclosed in a rigid web cover fitted with straps. The instrument is strapped snugly to the extremity to be studied. By a simple valve arrangement, the pouches can be inflated singly or together. A manometric dial records the oscillometric variations at different pressures. Air is pumped in until the pressure is great enough to prevent any movement of the oscillatory needle. By means of a needle valve, the pressure is reduced 10 millimeters at a time. Eight separate readings are taken of each extremity studied.

Normal values are recorded as follows: Upper extremities—rise begins at 120 millimeters of mercury and drops to zero between 40 to 30 millimeters of mercury. Maximal oscillometric phase occurs between 100 to 80 millimeters of mercury. Lower extremities—rise begins at 160 millimeters of mercury and drops to zero around 40 millimeters of mercury. Maximal oscillometric phase occurs somewhat above 100 millimeters of mercury. In obliterative vascular disease, oscillations occur over a much narrower range of pressure.

It is possible, by means of this apparatus, to determine the level of vascular obstruction, the intensity of myocardial contractions and the elasticity of the vessel walls.

9. *Spinal Anesthesia.*—Morton and Scott found that if the sympathetic fibers innervating the blood vessels of the lower extremities were completely paralyzed, under temperature-controlled conditions, vasomotor spasm could be differentiated from organic obstruction.

Procain Hydrochlorid 0.100 to 0.120 gram is dissolved in a small amount of spinal fluid and rapidly injected intraspinally. Skin temperature measurements are taken at five or ten-minute intervals, as well as the pulse rate and blood pressure.

Three types of reaction are recorded: (1) no change in gradient, pointing to entire absence of vasospasm; (2) complete obliteration of the gradient, indicating that the peripheral disturbance is due entirely to vasomotor spasm; and (3) partial obliteration of the gradient, the peripheral surface temperature definitely elevated, but not reaching the normal vasodilatation level, demonstrating a mixture of vasospasm and obliterative processes.

Exceptions to the above for normal vessel response are found in patients with fever, or in those suffering from advanced carcinoma.

The normal vasodilatation-level has been fixed by the authors at 33 Centigrade. To estimate the element of organic obstruction in vascular disease, the maximum surface temperature reached after sympathetic paralysis is subtracted from this figure, this difference being termed the obstruction index.

Similar information, while not as complete or as accurate, may be secured by peripheral nerve block or paravertebral ganglion anesthesia.

10. *Arteriography.*—One of the measures outlined above usually suffices to differentiate between spasm and obliteration of the peripheral vessels, but there remains a comparatively small group of cases in which visualization of the peripheral arterial tree is extremely important as a diagnostic aid. Arteriography furnishes definite and useful information regarding the extent of the disease, the nature of the pathologic process and the physiologic compensation for the diminished flow of arterial blood as a result of occlusion of the main arterial passages.

Thorotrast, an opaque slightly radioactive substance, is utilized for this purpose. It is composed, by weight, of 19 to 20 per cent thorium oxid, and 16 to 19 per cent of a protective colloid. When introduced into the arterial circulation, it is engulfed by the reticulo-endothelial cells and very slowly excreted. The effects of its prolonged deposition within the body are, as yet, largely unknown.

The drug is injected in amounts varying from five to twenty cubic centimeters, depending upon the size of the subject and the area to be visualized, directly into the brachial or femoral arteries. Pressure is made and maintained above the site of injection, while a series of rapid x-ray exposures are made.

HYPERTENSION: ITS SURGICAL APPROACH

By Francis M. Findlay, M.D.
Santa Barbara

Discussion *by Alfred E. Koehler, M.D., Santa Barbara; Franklin R. Nuzum, M.D., Santa Barbara; E. F. Holman, M.D., San Francisco.*

Introduction: Operative results in over two hundred cases of hypertension were reported by various surgeons* at the recent meeting of the American College of Surgeons in San Francisco. In a small percentage of these hypertensive cases, the blood pressure has been maintained at a normal level for periods of from several months to two years after operation. These investigators also observed a definite amelioration of symptoms and an appreciable drop in blood pressure in over one-half of the operated cases. Such encouraging results, in a condition that has previously failed to respond to any medical measures, cannot be ignored. Every member of the medical profession should know of the recent progress in this field.

OUTLINE

It is the purpose of this paper, first, to restate the known physiologic and pathologic changes that accompany essential hypertension. Second, to review the fundamental structure and function of the sympathetic and adrenal systems, and to point out their probable influence upon blood pressure. Third, to describe briefly the operative procedures now in use, and attempt to evaluate them. Finally, to propose a more extensive operation, based upon our present anatomic and physiologic knowledge plus the experience gained from previous operations done upon the sympathetic and adrenal systems.

DEFINITION

Both pioneers and present workers in this field have been handicapped because the etiology of essential hypertension is unknown. In describing the condition, Sir William Osler stated: "The exact cause of this high tension is unknown. Some have attributed it to overactivity of the adrenals, but it is much more likely that the primary difficulty is somewhere in the capillary bed—in that short space where the real business of life is transacted." Osler described this condition as simple high tension without signs of arterial or renal disease, and favored Clifford Allbutt's term "hyperpiesa." The condition is well known to be a progressive disease, often occurring in young people. It is characterized in the majority of cases in its early stages by periods of excessive rise in blood pressure without other evidences of pathologic change or disease, and is commonly termed "primary" or "essential" hypertension.

The pathologic changes in the kidney, heart, and blood vessels that result from hypertension have been described. The symptoms due to hypertension are well known. Internists can forecast the probable outcome in a series of cases with a fair degree of accuracy; yet this ability to describe the phenomena related to hypertension affords no

clue to the underlying cause. Many theories have been advanced as to its cause. Although hardening of the arteries often accompanies hypertension, it is improbable that arteriosclerosis ever causes hypertension. Kidney disease alone is responsible for only a small percentage of the total number of cases seen. No doubt there are some hereditary factors, for it is known that hypertension tends to run in families, and that men develop it more often than women. It is often associated with thyrotoxicosis and the menopause. Nervous tension and emotional distress contribute to its advance, and the disease usually progresses in spite of the most conservative or radical medical regimen.

STAGES OF HYPERTENSION

Livingston arbitrarily divides typical essential hypertension into five periods or phases. In the first phase, there is no permanent elevation of the blood pressure, and no kidney, heart or vascular lesions can be detected. However, the patient shows an increasing tendency to respond to minor physical and emotional stimuli by an excessive rise in blood pressure. Frequent observation reveals marked alterations in blood pressure during the twenty-four hours.

In the second phase, the pressure fluctuations become more acute and prolonged, and the blood pressure does not return to normal levels, but remains permanently elevated. While organic lesions have no doubt already appeared in the arterioles, they are not clinically demonstrable.

In the third phase, fibrosis of the arterioles with narrowing of the lumen can be seen under the microscope, and there may appear signs of kidney damage and perhaps an albuminuric retinitis.

In the fourth phase, the patient begins to experience symptoms ascribable to hypertension. There may be tinnitis, headache, dizziness or transient cerebral symptoms, failure of vision, kidney symptoms, or complaints indicating that the heart is no longer able to carry on efficiently under the excessive load.

Finally, if the patient is not carried off by some intercurrent infection or accident, he dies as a direct or indirect result of the arteriolar lesions, usually from a cerebral accident, uremia, or cardiac failure. The term "malignant hypertension" has been reserved for the cases that rapidly progress to fatal termination within a few months after the onset of the initial symptoms.

In our experience, the symptoms of headache, pulsation of the vessels of the neck, nervousness, and a sense of constriction in the chest occur much earlier in the course of the disease than Livingston indicates. We would also emphasize the extreme rapidity with which some of the younger cases progress, often ending fatally within a few weeks from the initial onset of the first symptom.

However, we must finally conclude that the fundamental cause of essential hypertension is still unknown. Any attempt to deal with this condition must be undertaken with this fact in mind. The various surgical attempts now being made may not only relieve the symptoms of hypertension, but may contribute some fundamental facts toward the real cause of essential hypertension.

CLASSIFICATION OF CASES

Because the etiology of primary or essential hypertension is not clearly known, much confusion exists in classifying and selecting cases. In the operated cases reported to date, there has been no apparent effort to separate the true cases of early essential hypertension from those with extensive renal damage or gross organic changes in the vessel walls. Several of these cases had marked changes in the fundus oculi; in a few retinal hemorrhages were recorded prior to operation, some had partial paralysis of an extremity from previous stroke; while in others there were urinary findings indicating extensive kidney damage from glomerular nephritis. All operators, however, agree that patients in the younger age groups with hypertensive symptoms of persistent nature, with minimal evidence of organic arterial change and without permanent renal damage, are the best candidates for operation and offer favorable prospects for a cure.

In general it seems that gross arteriosclerotic changes in any individual, marked impairment of renal function or other secondary complications

would be a contraindication at the present time for this type of operation. On the other hand, some surgeons have felt that until further knowledge is at hand, there are no real contraindications, and the operation should be done on all individuals with a systolic blood pressure over two hundred, disregarding other evidences of advanced pathology.

DETAILED DESCRIPTION ESSENTIAL

It is essential in the future that any report of cases include a careful description of the type of cases selected for operation. Observations should be recorded as to the vascular condition, the flexibility and range of the blood pressure, the elasticity of the blood vessels, kidney and urinary changes present in each individual prior to operation, as well as the fact that the systolic blood pressure is usually over two hundred. Cases should be followed at frequent intervals for at least a year before results are reported. It is impossible to compare results obtained by different surgeons during the past two years, because the standards for selection of cases have varied. Most of the preliminary reports submitted have not included a detailed study of each individual case. No doubt future reports will give us added details and a clearer picture of each operated hypertensive case.

NORMAL VARIATIONS IN BLOOD PRESSURE

In any consideration of hypertension it is essential to remember that many individuals at intervals in their youth and young adult life may show periods when their blood pressure readings are distinctly above normal, yet in later life will have normal pressure. Single readings have very little value in determining the true status of an individual who is suspected of having essential hypertension. Only by repeated observations over a long period of time can the true picture be seen. Many young individuals from nervousness or some other cause show abnormally high readings of the blood pressure at the first examination, yet repeated subsequent examinations show normal values. With these facts in mind, no patient should be subjected to a procedure which is still definitely experimental until careful observation has shown that individual to be a true case of essential hypertension and that other measures fail to give reasonable prospects of recovery.

SYMPATHETIC ADRENAL INFLUENCE

Because no definite etiologic factors have been found, some writers have assumed that a constitutional abnormality of the sympathetico-adrenal system plays an important part in the production of essential hypertension. Before discussing the surgical approach in this condition, a brief review of the known facts concerning the structure and function of the autonomic nervous system, and the adrenal glands and their possible influence upon hypertension is indicated. The normal anatomy and physiology of the sympathetic nervous system is not well known by the average surgeon today.

AUTONOMIC INFLUENCE

Our knowledge of the autonomic nervous system and its influence upon the circulation, although gradually accumulated, is still incomplete. Galen, John Hunter, Brown-Séquard, Claude Bernard, François-Franck, Cannon, and Leriche have each contributed to our fund of knowledge. Bernard showed that the remarkable ability of the body to maintain a constant temperature, in spite of its changing external environment, was made possible by the autonomic nervous system through its influence upon the vasoconstrictors and vasodilators of the blood vessels. Cannon showed that it was the sympathetic division which controlled vasoconstriction of the blood vessels, and that surgical shock, with its pronounced fall in blood pressure, was in large degree due to dilatation of the visceral blood vessels.

SYMPATHETIC CONTROL THROUGH BLOOD VESSELS

Accumulated observations of many workers show that apparently the entire sympathetic control of our extremities, and of many of our organs, is exercised through the action of the vasoconstrictors of the blood vessels to these parts.

The increase in temperature of an extremity, either following spinal anesthesia or blocking of the peripheral nerves with novocain or alcohol, is entirely dependent upon the increased blood supply which follows temporary or permanent interruption of the sympathetic influences which affect constriction of the blood vessels.

On the other hand, the disturbed vasospastic mechanism of Raynaud's disease, with the lowered temperature in the affected extremity, the cold, clammy, cyanotic digits and the pain from anoxemia, quite definitely demonstrates the diminished blood supply which follows increased sympathetic activity, and its effect upon the blood vessels of the extremity. Although increased adrenalin secretion is probably the cause of this increased vasomotor discharge, it seems quite clear that sympathetic control of the extremity is exerted entirely through the vasoconstrictor fibers to the blood vessels.

This same mechanism that controls the rate of blood flow in the extremities is apparently the chief factor in the sympathetic control of various organs and glands within the body cavity. Claude Bernard, in 1877, first showed that cutting the splanchnic nerves increased the blood flow to the kidney with increased secretion of urine. This observation has been confirmed more recently by Quinby, Sangree, and Hess, and other observers, both in animals and in man. All investigators agree that sympathetic denervation of the kidney causes no change in the elimination by the kidney of salt, urea, and many other substances. These findings suggest absence of actual secretory fibers to the glomerular tubules, and that the splanchnic nerve's only action on the kidney is to control the amount of blood flow through the renal vessels.

This action of the autonomic nervous system upon blood vessels is again demonstrated in the sex organs where sexual excitement is accompanied by engorgement of the blood vessels to that region. Kuntz showed, in 1929, that although the ovary is abundantly supplied with nerve fibers, the distribution of these is limited to the blood vessels, and that the engorgement of all pelvic organs is the direct result of sympathetic action upon blood supply. This physiologic fact that the sympathetic nerve supply is chiefly directed to the control of blood flow to the extremities, organs and glands in various parts of the body, seems to be the real basis for the hope of lowering blood pressure in cases of true essential hypertension.

RENAL VASOCONSTRICTION A FACTOR

Further study of the sympathetic influence upon the circulation has led to the discovery of another mechanism, renal vasoconstriction, which appears to be a factor in the production of essential hypertension. The production of renal ischemia by clamping the renal arteries in dogs has produced an experimental form of hypertension that is similar in many respects to essential hypertension as seen in man. Two workers have thrown considerable light upon the underlying problem of hypertension. Richards has recently shown that stimulation of the splanchnic nerves will increase aortic blood pressure by causing vasoconstriction of the afferent artery to the glomerulus. This, of course, produces diminished glomerular pressure with consequent impairment of kidney function. It was previously thought that essential hypertension was due to a generalized vasospasm of the entire arterial system. This is the first time that it has been shown that constriction of a single portion of circulatory system will result in hypertension.

Supplementing these observations, Goldblatt, and his co-workers, in a group of very carefully controlled experiments, have produced and maintained hypertension in a group of dogs for an average period of over one year. He accomplished this by producing constant renal ischemia with a clamp upon the renal arteries. He has shown that it is essential to produce renal ischemia rather than limit the circulation to other parts of the body; for vasoconstriction of other large vessels like the splenic and the iliac arteries failed to alter the blood pressure.

While Richards and Goldblatt have not as yet explained the mechanism of this elevation of blood pressure, they have shown that renal ischemia is a factor. Since renal artery vasoconstriction produces hypertension and since splanchnic nerve stimulation increased blood pressure while decreasing kidney function in experimental animals, it logically follows that there may be some cases of hypertension in man due to renal artery vasoconstriction. These cases should improve from splanchnic nerve section by increasing kidney circulation and lowering blood pressure.

ADRENAL INFLUENCE

The influence that the adrenal glands exert in the production of hypertension is not definitely known. Many facts point toward these glands as being intimately associated with the production of hypertension. Embryologically the origin of the medullary portion of the adrenal, and of the sympathetic nervous system are identical. Their cells show similar histologic structure. Epinephrin, which is elaborated in the medullary portion of the gland, exerts its physiologic effect primarily upon the muscles which constrict the blood vessels which in turn are innervated by sympathetic fibers.

Koehler has observed that the adrenalin content in the suprarenal glands removed at operation in a small series of hypertensive cases is roughly proportional to the elevation in blood pressure. Although some of the glands contained less adrenalin than is usually considered the normal value, his patients with the highest blood pressure had the most adrenalin in their suprarenal glands, while those with the lower pressure readings consistently had less adrenalin in their glands.

Pincoffs has reported two cases of medullary tumor of the adrenal associated with severe hypertension. Removal of the tumor in both of these cases resulted in return of normal blood pressure. Porter, Shipley, and Belt have also reported similar cases of medullary tumor accompanied by hypertension. The vast majority of cases of hypertension, however, show no tumor of either adrenal. Crile and Goldzieher have maintained that hyperactivity of the medullary portion of the adrenal was the fundamental cause of this elevated blood pressure, and have likened the condition to hyperthyroidism. Aside from the occasional medullary tumor, no definite pathologic change has been discovered to date in the adrenals of individuals suffering from hypertension. The analogy between the thyroid gland in hyperthyroidism and the adrenal gland in hypertension does not seem to be justified.

Other evidence tends to show that the adrenals exert little or no influence in hypertension. Hines and Brown have shown that bilateral adrenalectomy in dogs does not prevent the pressor response to cold. The consensus of opinion, as represented by the works of Page and Heuer and Soma Weiss, seems to be that there is no evidence of an increased amount of pressor substance in the blood in essential hypertension as determined by either chemical means or vascular responses.

However, the embryologic development and the histologic structure of the adrenal medulla, with its large sympathetic nerve supply, lead the careful observer to conclude that there is some definite relationship between the adrenal glands and the autonomic nervous system.

ADRENAL SURGERY

Surgical attempts to control hypertension to date have consisted in operations upon the adrenal glands and upon various portions of the sympathetic nervous system.

Over twenty years ago Crile practiced partial adrenalectomy and denervation of the opposite adrenal to control hypertension. He writes that his results have been unsatisfactory and two years ago he gave up partial adrenalectomy and denervation for resection of the splanchnics. De Courcey, at the present time, champions the cause of the adrenal. He has advocated and practiced subtotal bilateral adrenalectomy with striking immediate results. White feels that his cases have been followed for too brief a period to draw any conclusions as to final results. Lahey, Smithwick, and Palmer have been unable to duplicate the favorable results of De Courcey and have given up the operation. Ussher has observed favorable results from bilateral subtotal adrenalectomy in a single patient carefully observed and followed for over a year. Koehler records a striking drop in blood pressure following bilateral adrenalectomy in a case followed for six months. It is too soon to discard the adrenal entirely.

It is improbable that bilateral adrenalectomy will have many advocates until its superior advantages over other procedures are shown, for the immediate operative risk in adrenalectomy is considerable, several operative deaths have occurred, and the danger of acute adrenal insufficiency developing is very great.

SYMPATHETIC SURGERY

Many observers have thought that interruption of the vasoconstrictor influences to a large portion of the vascular bed would have a depressor effect in early cases of essential hypertension. As the splanchnic nerves control a large portion of the visceral blood supply, they have been among the first objects of surgical attack.

Danielopolu first suggested resection of the splanchnic nerves for hypertension in 1923. Pende, in 1925, proposed section of the left splanchnic nerves, and Pieri, in 1930, actually did unilateral section of the splanchnic nerves for hypertension. Peet was first in this country to do bilateral resection of the splanchnics for hypertension, and has reported one hundred patients upon whom this procedure has been carried out in the past three years. Craig has also advocated a similar operation.

The results obtained by surgeons to date have been quite uniform in that section of the splanchnic nerves has resulted in an immediate drop of at least forty to fifty points in the systolic blood pressure, but in many cases this improvement has been only temporary and careful observation warrants the belief that either insufficient fibers have been removed or else regeneration has taken place. Adson and Mixter have both reported cases in which rhizotomy of the posterior roots of the lower dorsal and upper lumbar segments have resulted in marked fall in pressure that is apparently permanent, so that it is quite evident that interruption of enough sympathetic fibers will lower the blood pressure.

OPERATIVE TECHNIQUE

The technique that Peet follows for resection of the splanchnic nerves consists in bilateral removal of a section of the greater splanchnic nerve about eight centimeters long, together with excision of the tenth, eleventh, and twelfth dorsal sympathetic ganglia, and the lesser and least splanchnic nerves, if present. This operation is done above the diaphragm through a posterior incision with resection of small portions of the eleventh rib, and is accomplished with a minimum of shock to the patient.

Adson and Craig of the Mayo Clinic advocate division of the splanchnics below the diaphragm with removal of the first or second lumbar sympathetic ganglia to interrupt the ganglionic chains, and more recently have combined this operation with partial adrenalectomy.

We are considerably stimulated in the study of essential hypertension by the various attempts that have been made to attack the problem surgically. It is quite evident from the variable results which have been reported that we have not found the ideal operation.

INCOMPLETE DENERVATION

Failure in many instances would appear to be due to incomplete removal of all the sympathetic nerve supply. We must remember that the autonomic nervous system is not a separate and distinct unit, but that it has many connections with the central nervous system. The splanchnic nerves especially are made up of many different preganglionic fibers which regenerate rapidly unless the cell bodies from which they arise are destroyed. Smithwick, Freeman, and White have shown that regeneration of preganglionic fibers takes place within a week. Bard feels that the secretory fibers going to the adrenal medulla regenerate very rapidly. It is quite certain from our present evidence that an adequate drop in blood pressure can be obtained in many hypertensive cases if sympathetic fibers can be completely and permanently removed from an adequate visceral area. Both Adson and Mixter have shown that posterior rhizotomy lowers blood pressure, but is too crippling an operation for practical use. It would appear that more complete removal of the splanchnic nerves is the next logical step in this approach. This, no doubt, has been in the minds of other workers, but we are not aware that the procedure has been carried out.

FACTS FAVORING EXTENSIVE GANGLIONECTOMY

Holman has observed that section of the major splanchnic nerve in man consistently accounts for a marked immediate drop in the systolic blood pressure, while section of the splanchnic minor, which innervates chiefly the adrenal glands, is accompanied by relatively little change. The major splanchnic is the main nerve supply of the renal blood vessels, and section of it probably causes vasodilation of the renal afferent arteries with increased renal circulation, and subsequent lowering of the systemic blood pressure. The splanchnic nerves are composed chiefly of preganglionic fibers, which regenerate rapidly in animals and presumably in man unless the cells from which they arise are destroyed. Section of these nerves should be accompanied by removal of the fifth to twelfth dorsal sympathetic ganglia to effect permanent denervation. The present operations of removing only the tenth to twelfth dorsal ganglia divide only the origin of the splanchnic minor and least nerves, as the splanchnic major receives fibers from the fifth to ninth dorsal ganglia inclusive. The present operation is, hence, an incomplete denervation.

This operation can readily be performed through a posterior incision, removing a section of the seventh rib in a similar manner to the present operation for removing the lower dorsal ganglia. It is true that all these procedures have possible grave dangers in the disturbances of motility of the gastro-intestinal tract, and altered secretion of other glands and organs innervated by the splanchnic nerves. However, section of the splanchnic nerves and removal of sympathetic ganglia do not carry the immediate operative mortality associated with adrenalectomy, or result in extensive paralysis of the abdominal muscles that follows rhizotomy. Until further study reveals more of the etiology of this condition, this procedure would seem warranted on some of the cases of hypertension which are not responding to more conservative measures.

SUMMARY

1. While the etiology of hypertension is unknown, the physiologic and pathologic changes characteristic of the disease have been reviewed.

2. The sympathetic nervous system plays a large part in the control of blood pressure. Increased sympathetic discharge or altered adrenal secretion would appear to be a large factor in the production of hypertension.

3. Present operative attempts show promising results in a large number of cases and warrant careful study of all factors involved.

4. Further modification of present procedure is suggested, based upon our past experience and anatomic facts.

1515 State Street.

DISCUSSION

Alfred E. Koehler, M. D. (317 West Pueblo Street, Santa Barbara).—Doctor Findlay has presented a timely review of an exceedingly important problem. The internist will have to concede, at least for the present, that the surgeon has made an aggressive attack on the hypertensive problem that merits consideration as a most promising therapeutic measure. The present methods of approach, either sympathetic resection or suprarenal surgery, will be instrumental after the elapse of some years in yielding information not only as to the therapeutic value of these procedures, but as to the etiology of hypertension.

Our approach in Santa Barbara has been largely that of bilateral partial suprarenalectomy. Some of our cases have gone from one to two years after operation, and there can be no doubt as to the dramatic reduction in blood pressure. As yet we have seen no evidence of suprarenal regeneration. Our policy has been to wait at least three months between the first and second stage, thus giving sufficient time for complete organization of the gland remnant. We believe this to be highly important in reducing mortality.

We have been prejudiced against sympathetic resection for the following reasons: (1) The fibers cut are postganglionic and, therefore, will regenerate in a comparatively short period of time. (2) Sympathectomy, after a period of time, markedly increases the vascular sensitivity to epinephrin. (3) Relief after lumbar sympathectomy is only visceral and, consequently, does not relieve peripheral arteriole spasm. Lowering of systemic blood pressure without removing peripheral resistance must result in diminished circulatory efficiency in these tissues. (4) Visceral sympathectomies may interfere in bowel innervation and function.

Of utmost importance in any procedure is thorough observation and study of the various factors related to hypertension for long periods, both before and after operation.

⁂

Franklin R. Nuzum, M. D. (Cottage Hospital, Santa Barbara).—Limiting this discussion to conclusion No. 2 of the summary, that "the sympathetic nervous system plays a large part in the control of blood pressure," and "increased sympathetic discharge or altered adrenal secretion would appear to be a large factor in the production of hypertension,'" the notion that an increased production of adrenalin is an etiologic factor in hypertension is of long standing. Numerous attempts have been made to measure the amount of adrenalin in the blood stream. There are now recorded upward of one hundred such chemical tests. The number bespeaks the nonacceptance of any one. The biologic method of assay is difficult and time-consuming in technique. By such methods it has been determined that the concentration of adrenalin in the blood leaving the adrenal vein is one part to 350,000; in the circulating blood, the concentration is about one part to 100,000,000. With such a dilution, it has been, and is as yet impossible to say that adrenalin *per se* is associated with the etiology of hypertension.

Many physiologists, especially Cannon, believe that adrenalin is discharged intermittently during times of fear, anger, etc. Their notions are opposed to this agent's being an etiologic factor in hypertension. It is fair to say that the thesis remains to be proved; that adrenalin is etiologically important in this situation, and that only time will prove or disprove the efficacy of the surgical measures now being advocated for the treatment of this widespread and important condition.

⁂

E. F. Holman, M. D. (Stanford University Medical School, San Francisco). — The problem of hypertension has been ably presented by Doctor Findlay. Ignorant of its etiology, clinicians are groping rather blindly for some method more effective than any medical treatment so far presented. At present one can predict with considerable assurance the probable outcome in a given case, treated or untreated. To modify the hitherto inexorable progress of the disease, various operations are being employed, obviously empirical, since the cause of hypertension is unknown. Such empirical measures can result only in a marked diversity of results.

The reported successes following splanchnicectomy are encouraging, yet again, one cannot predict with any certainty what the outcome will be. The tangible benefits in our experience have been a definite subjective improvement in all, but a marked lowering of the blood pressure in only two of the eight cases subjected to this operation. Such experience will undoubtedly tend to restrict the operation much more rigidly to a narrow group, namely, younger patients who show few evidences of peripheral and retinal arteriosclerosis and a minimal damage to the kidneys. Because of its experimental nature, the operation should not be universally applied, but limited to such clinics as are able and willing to conduct all the studies designed to give a better understanding of the disease and a clearer appraisal of all the effects of the operation, beneficial or otherwise, upon the organs supplied by the splanchnic nerves.

⁂

Doctor Findlay (Closing).—I am deeply indebted to the discussers of this paper for their kind criticism, and I wish to express my appreciation to them for reviewing this communication.

Doctor Koehler has given four objections to sympathetic resection. A more extensive ganglionectomy such as outlined in this paper will prevent regeneration of the splanchnic nerves, and thus remove his first objection. His second objection, that the denervated extremity has increased sensitivity to adrenalin, is valid. It appears inconceivable, however, that subtotal removal of both adrenals could come any nearer solving the problem when physiologic responses in normal individuals are obtained from blood serum containing only one part of adrenalin in 100,000,000. Since it has not been demonstrated that all of the pathology of essential hypertension lies in the capillary bed, or that increased adrenal secretion is the cause, his third objection holds against adrenalectomy as well as against sympathectomy. His fourth objection should not be ignored; but Cannon's work on animals and the clinical observations upon human patients who have been subjected to extensive sympathetic surgery, fail to show any serious interference with the function of the gastro-intestinal tract.

I am glad that Doctor Nuzum has reëmphasized that the etiology of essential hypertension is unknown. Any assumption that altered adrenal secretion is a factor in its production is still an unproved theory rather than an established fact.

I am grateful to Doctor Holman for so kindly adding his own experience and reminding us that progress in this field will not be made unless careful and thorough preliminary studies by competent observers precede surgery. A thorough follow-up over a period of several years, with complete reporting of failures as well as successes, will enable us in time to appraise our work.

We are well aware that the answer to this problem may lie entirely outside the field of surgery, possibly in the field of endocrinology or biochemistry.

THE MEDICAL MANAGEMENT OF PEPTIC ULCER*

By George A. Cochran, M.D.
Salt Lake City, Utah

Discussion *by Lowell D. Snorf, M.D., Chicago, Illinois; Frederick A. Speik, M.D., Los Angeles.*

PEPTIC ulcer seems to be increasing, due to nervous tension attributable to our complex living requirements. The causes may be (1) nervous tension, (2) heredity and family tendency patterns, and (3) focal or residual infections of the blood vessels in the stomach and duodenum. The hydrochloric acid secretion is a necessary concomitant factor for the formation or continuation of the ulcer. The statement that these ulcers are peptic is accepted universally.

ETIOLOGY

Ulcer patients, as a type, display nervous tension and irritability, and do not readily relax. It has been noted that among the Indians of Mexico ulcer is unknown,[1] although coarse and deficient food and unhygienic living prevail. As coronary and sclerotic heart disease occur in the high-pressure brain worker, likewise ulcer is common in this class. Ulcer is not infrequently associated with brain injuries and tumors. Emotional stimuli cause a pouring out of epinephrin, which produces vascular spasm, ischemia and necrosis, and the hydrochloric acid completes the ulcerative processes.

We are often impressed with the history of ulcer in families. I have in mind a family in which the father and five of eight children were found to have peptic ulcer. The male sex is susceptible in the ratio of five or six to one, in large series of ulcer cases.

CLINICAL HISTORY

The manifestations of ulcer are only recognized by a careful clinical history. Experience is a requisite in acquiring a technique of diagnosis. A majority of patients have a history of having had stomach trouble for ten or more years. Occasionally we see cases which have had symptoms for only two or three months, and alertness is essential or the diagnosis may be missed. Cases of short duration must be studied with thoroughness because of the possibility of malignancy. Intermittent dyspepsia over fifteen or twenty years removes them from the latter class. Ulcer patients are characterized by periodicity of symptoms; but as the disease progresses the periods of freedom are shortened, and with the development of the complications of pyloric spasm, food retention, continued secretion, and involvement of deeper structures, the symptoms are persistent.

The distress of ulcer may be described as dull pain, burning in the epigastrium, feeling of fullness or merely discomfort. In uncomplicated ulcer, the pain is sharply localized to the epigastrium.

---

* Read before the Nevada State Medical Association at its thirty-second annual session, Elko, October, 25-26, 1935.

[1] Statement of physicians interviewed by author while on tour of Mexico in August and July, 1935.

The relationship of pain is important, usually appearing one to four hours after a meal. The notion that pain coming late in the food-relief-pain cycle is pathognomonic of duodenal ulcer, is not borne out by experience. The exact localization of the ulcer can be made out by aid of the fluoroscope in about 75 per cent of cases.

The distress of peptic ulcer is relieved by food, alkalies, and induced vomiting. When the history obtained is indefinite, it is customary to have the patient keep daily notes of the location of the pain and time of onset, and make a test for relief by an alkali. The final diagnosis will many times stand on a therapeutic test.

DIAGNOSTIC AIDS

The fluoroscope contributes valuable diagnostic evidence. Visualization of a crater in the wall of the stomach, or a niche in the first inch of the duodenum, is direct evidence. A deformed duodenal cap, a large stomach with more than two vigorous peristaltic waves appearing at one time, and delayed emptying are indirect evidence of duodenal ulcer.

No diagnostic technique on the stomach or duodenum is complete without a study of the secretions. There must be an adequate acidity in peptic ulcer. We use a fifty-minute Ewald test-meal. A shredded wheat biscuit or two slices of white bread with 360 cubic centimeters of tap water, is given on the fasting stomach. If the acid values are low, or there is an achlorhydria, a two-hour fractional test is run with the Rehfuss tube. This is repeated with stimulation by histamin hypodermically, if hydrochloric acid is not found. When an excessive quantity of secretion is obtained, or there is a history of night distress, retention is suspected. This may be due to pyloric spasm, organic tissue narrowing at the pylorus, hypersecretion, or inflammatory swelling and edema. These cases are given a motility test-meal. This consists of a large meal of bread, potatoes, roast beef, two cooked vegetables, a fruit, and dessert. At the end of seven hours the No. 38 French tube with large bulb is passed, the stomach lavaged and the contents measured. More than 100 cubic centimeters of food and secretion is evidence of retention. Nausea accompanying migraine or extragastric disease inhibits peristalsis and gives pseudo-retention. The barium meal is a less reliable test of motility because of the fluidity of the material.

SIPPY METHOD

Several systems of ulcer treatment have been devised. The Sippy ulcer management has been quite generally and successfully used. This is the method herein described. The patient is confined to bed, and preferably in a hospital, which insures professional supervision and meets the requirements for physical and mental rest. Three ounces of a milk and cream mixture (22 per cent cream) is given every hour from 7 a. m. to 7 p. m. An alkali is given halfway between these feedings, or from 7:30 a. m. hourly to 7:30 p. m., and at 8 and 9 o'clock. On the fifth day, if all symptoms are relieved an additional four-ounce feeding of a well-cooked cereal, such as Pearls or Cream of Wheat, is given at 8 a. m. On the seventh or eighth day, depending on the nutrition of the patient, extra feedings of a soft egg and slice of white toast and butter is given at 12 o'clock, and a soft custard at 5 p. m. Four ounces of strained orange juice are given with the morning feeding, and four ounces of tomato juice with the noon. At the end of two weeks additional feedings are added. These consist of cream vegetable soups, blanc mange, milk and cream, and well-cooked rice, with cream and sugar. At the end of three weeks, the full caloric requirements of the patient are supplied. These must be foods which leave the stomach rapidly and stimulate the minimum of secretion. This food very largely consists of equal parts milk and cream, cooked or flaked cereals, soft eggs, white toast and butter, orange and tomato juice, baked potato, trout, lamb, vegetable purees, cream vegetable soups, soft custards, and ice cream.

Some cases of simple, uncomplicated ulcer will respond to an ambulatory management of three meals at 8 a. m. 12, and 5 p. m., with an alkaline powder immediately after the meals, and a glass of milk and cream at 10 a. m. and 3 p. m. The five o'clock meal, however, should be light, and consist of only well-cooked cereal with cream and sugar or soft custard and a glass of half milk and cream.

The purpose of the ulcer treatment is to promote healing, and to facilitate this an alkali must be given in sufficient quantity to reduce or completely neutralize the hydrochloric acid. In cases in which there is no evidence of hypertension, kidney dysfunction, or liver impairment, a tablet is given, consisting of twenty-five grains of sodium bicarbonate, fifteen grains of calcium carbonate, and seven and one-half grains of bismuth. A tablet is used because of the attainment of exact dosage. Cases which exhibit some intoxication with bicarbonate are given, instead, tablets of tribasic calcium phosphate twenty grains, and tribasic magnesium phosphate 15 grains. Magnesium oxid is not used because of the tendency to upset the bowel and create nausea from increased intestinal pressure. A rectal examination with the gloved finger is made frequently, and an eight-ounce warm water enema given if indicated.

COMPLICATIONS

The complications of ulcer are perforation, hemorrhage, pyloric spasm, organic tissue narrowing of the pylorus and bulb of the duodenum, inflammatory swelling and edema from an ulcer near the pylorus, continued or hypersecretion, and malignant degeneration.

Perforation requires surgical treatment as soon as the diagnosis is established. The severe abdominal pain, board-like rigidity of the recti, shock, pallor, rapid, thready pulse, and a history of dyspepsia are seldom confusing.

Hemorrhage of a massive character occurs in ulcer, cirrhosis of the liver, and Banti's disease. Only slow oozing is exhibited in malignancy of the stomach. The patient is put to bed and given one-quarter grain of morphin hypodermically every four hours, or sufficient to control restlessness. Twenty grains of calcium carbonate in two ounces of water are given every two hours during the day, and every three hours throughout the night. After four days a regular ulcer management may be instituted. The very rare case in which hemorrhage cannot be controlled by this treatment must be transfused and treated surgically.

Food retention caused by pyloric spasm, edema and inflammatory swelling, the result of an ulcer near the pylorus, either on the stomach or duodenal side, must be treated by the regular ulcer management, and in addition the stomach is emptied of its contents every night at 10 o'clock until nothing is obtained. In severe obstruction cases with continued secretion, a second nightly aspiration at midnight is necessary. If symptoms of intoxication or tetany are exhibited, an infusion of 500 cubic centimeters of normal salt solution with 5 per cent glucose is given daily. If these cases do not give evidence of decreasing retention in four weeks, they are treated surgically.[2] The continued secretion is due to pyloric obstruction, and disappears with the improvement of this condition.

IN CONCLUSION

It is not exaggeration to insist that 85 per cent of peptic ulcer cases can be cured or symptomatically relieved by accurate and adequate medical treatment. To achieve this result, the disease must be taken seriously in its early stages. Persistency in carrying out details and rigid supervision by the doctor are essential for success. There is no disease which is so satisfactory to treat and in which the patient is so fully restored to normal function.

1001 Medical Arts Building.

DISCUSSION

Lowell D. Snorf, M. D. (25 East Washington Street, Chicago, Illinois).—Doctor Cochran's brief review of the management of ulcer is very concise and refreshing. Furthermore, it is timely. The continued importance given to this subject means a more rational attitude of treatment among a larger group of physicians. The failures of medical therapy in general may be attributable, as Moynihan has said, to its insufficiencies, and it at once becomes evident that if one hopes to succeed in the broader sense, to properly cope with the problem at all, he must be on the lookout for the ulcer, prompt at diagnosing it, and capable of planning a treatment. He must be fully cognizant of the potential invalidism ahead of any human in whom an ulcer is present. Early recognition is, therefore, imperative. Why wait for a chronic and recurrent picture to clinch the diagnosis? Why call the early ulcer by such terms as "hyperacidity" and "hyperchlorhydria"? Suspect the lesion, try to confirm it by x-ray, but always be alert to it as a possibility. If you do not, the shock to your vanity is of no consequence, but the time wasted for the patient is important. Recognize the clinical chemical distress syndrome, and remember the relative infrequency with which this is mimmicked by any other abdominal lesion. It will not be your good fortune to recognize all lesions in their incipiency. The chronic peptic lesions are a trial to both the internist and surgeon. Hemorrhage obstruction, continued secretion, and adhesions, are all possible, and one or another probable in the life cycle of the ulcer unless early management is instituted. Any successful treatment of a given case of peptic ulcer demands a careful evaluation of the possible causative factors, such as foci of infection, nervous instability, etc., the nature of the pathology and, finally, the type of treatment best suited for the individual.

The ulcer problem would lose much of its uncertainty if we were fully acquainted with its causes. We may well assume, however, that a local lowered resistance, vasomotor instability, and the peptic activity of the gastric juice are three factors probably constantly present and to which proper treatment can be applied. Only clinical experience and laboratory experimentation can finally answer these questions.

The dissension among clinicians of the past few years regarding the type of treatment most satisfactory has been due in a large measure to the lack of appreciation of the nature and varieties in pathology. The simple, uncomplicated ulcer will respond temporarily to almost any kind of management, while in general, when mechanical disturbances from high-grade obstruction and deep-cratered ulcers develop, surgery is usually required. Meticulous attention must always be given to details of diet and general hygiene and, particularly, a program of education for the patient must be set up.

To date the Sippy management must be considered the therapy of choice. A dogmatic medical routine is as essential to success as the definite program of the surgeon in doing a gastro-enterostomy. To follow a scheme haphazardly is to have no plan at all. A diet slip and a prescription without supervision or detailed explanation means failure. In general, a successful management will depend to a large extent upon a full appreciation of disturbed physiology and the morbid anatomy involved, plus an incorporated educational program for the patient.

⁂

Frederick A. Speik, M. D. (727 West Seventh Street, Los Angeles).—Regarding the article "The Medical Management of Peptic Ulcer," this paper of Doctor Cochran's is, in my opinion, very inclusive. Not much can be added except to say that in acute bleeding of ulcer, bismuth-subnitrate, in large and frequent doses at regular intervals, will shorten the bleeding time.

Let the patient alone as much as possible, and do not give hasty transfusions or intravenous glucose and salt.

IRRITANT FACTORS IN TOBACCO SMOKE

By Emil Bogen, M.D.
Olive View

Discussion *by C. H. Thienes, M. D., Los Angeles; Joseph Goldstein, M. D., Los Angeles.*

The average smoker is not particularly concerned over the remote prospects that smoking may, in his own case, cause or aggravate serious functional derangements or organic lesions such as cardiac arrhythmias, toxic amblyopia, or thromboangiitis obliterans. He is, however, usually anxious to avoid the immediate local irritation of the mouth and upper air passages, which detracts considerably from his enjoyment of a smoke.

Accordingly, although cigarette manufacturers have not hesitated to invoke the physiologic consequences of the absorption of nicotin as talking points in advertising, such as the interference with appetite or the reported rise in the blood sugar, by far the greatest stress in recent campaigns has been placed on the claim that particular brands are devoid of certain irritating properties which are tacitly admitted for tobacco in general.

IRRITATING NATURE OF TOBACCO SMOKE

That tobacco smoke is generally irritating to the mucous membranes may be reasonably inferred from the emphasis which has been placed upon relative freedom from this effect in recent advertisements. In his exhaustive review of "Tobacco and Physical Efficiency," Schrumpf-Pierron simply states that "smokers' laryngitis is too well known to require a description."[1] Even that vigorous defender of tobacco, Dr. Wingate Johnson, admits that "most inveterate smokers show a marked congestion of the pharynx, and many either clear their throat or cough habitually, regardless of the brand of tobacco smoked."[2] Nearly half of a group of subjects given "blindfold tests" some years ago stated that they suffered from biting and irritation, burning, coughing, hoarseness or salivation, as a direct result of smoking.[3]

---

[2] Dr. C. W. Mayo makes the statement that forty of the Mayo Clinic doctors have peptic ulcer, none of whom elected to be treated surgically.

In private conversation, as well as in paid interviews, many smokers have insisted that they could recognize a real difference in the irritating properties of the smoke from different brands of cigarettes. There is, however, little agreement among them as to which brands are less irritating. Psychologists have generally found that the average smoker is utterly unable to identify the brand of a cigarette when smoking blindfolded.[4] The uncontrolled subjective impressions of the smoker, accordingly, form an unreliable criterion of the relative irritating effects of different brands.

THE TEMPERATURE OF TOBACCO SMOKE

The irritating effect of tobacco smoke has been ascribed simply to heat "burning" the lips and mucous membranes. This factor appears especially important in connection with the cancers of the lower lip noted in devotees of short-stemmed clay pipes. Certain widely spread advertisements imply that it is also true of cigarette smoke. Experiments performed as indicated pictorially in these advertisements failed to show any significant increase in temperature of the inhaled smoke with an ordinary mercury thermometer.[5] It seems that this advertisement was merely "symbolic," as delicate methods, using a thermocouple, are necessary to show the actual temperature changes in smoke.[6]

Such accurate measurements show that the temperature of the smoke inhaled changes very little from that of room air during the burning of the first quarter of the cigarette. Then there is a gradual rise with successive puffs, until about one-half of the cigarette has been consumed, when the temperature usually reaches about that of the body. It continues to rise at an increasingly rapid rate as the stump of the cigarette is burned, when painfully hot smoke, laden with revolatilized nicotin and other substances previously condensed in the stump, may be obtained. Accordingly, a cigarette holder, with its constant temptation to smoke further down into the stump of a cigarette, may lead to actual burns from hot smoke, as well as to greater absorption of nicotin and other volatile constituents.

With a constant level of suction, as is described in some experiments, the rate of combustion of the tobacco, and consequently the temperature, reached in the smoke at any time would be lowered by increasing the resistance to the passage of air through the cigarette by pressure in filling or mounting it, moisture, or other factors. In actual practice, however, it seems that smokers generally adjust the strength of suction to the resistance encountered, so as to take in about the same volume of air with each puff. Different brands of cigarettes, including so-called mentholated ones, burned at the same rate when the same volume of air was drawn through them, independent of the strength of suction required to do this, and all then gave the same range of temperature when the same length of cigarette had been burned.

The subjective effect of coolness resulting from the application of menthol fumes to the mucous membranes, with, perhaps, a certain amount of temporary local anesthesia induced by this drug, may perhaps be noted when mentholated cigarettes are used; but it is doubtful whether this is a safe or desirable condition.

Special devices for lighting a cigarette without a hot flame, and the so-called "static" method of lighting a cigarette without suction, have been recommended in order to lessen the irritation from the hot first puffs. Since the temperature of the smoke is generally a function of the length of cigarette unburned, and the length is greatest at the time of lighting the cigarette, the slight differences of initial temperature so achieved are probably of little importance, as compared with that resulting from leaving too small a stump.

RÔLE OF NICOTIN

Despite the general belief that nicotin is the chief toxic factor in tobacco smoke, and the extravagant tirades against it by the manufacturers of so-called denicotinized preparations,[7] this substance probably plays little part in the local irritation from smoking. It has long been recognized that the "strength" or irritating properties of tobacco are independent of their nicotin content, so that Porto Rican cigarettes, with a low nicotin content, are frequently regarded as the most highly irritating.

Inasmuch as nicotin in the form of the free base is much more easily volatilized by heat than in the form of its salts, it has been suggested that the absorption of nicotin and the irritation from smoking might be related to the "free nicotin" or nicotin base present in the tobacco, rather than to the total nicotin content.[8] Studies of this "free nicotin" in cigarettes and other forms of tobacco show that this is, as might be expected, inversely proportional to the hydrogen ion concentration of the tobacco, and that actually it is greater in the Porto Rican cigarettes than in the American brands, and lowest in the Oriental cigarettes commonly reported to be less irritating. Treatment of the tobacco with citric acid has been suggested, accordingly, to lessen this factor.

The alkaloidal base, nicotin, is undoubtedly quite irritating, and its application to the skin of a mouse or the eye of a rabbit may give rise to local inflammation and even ulceration. This, however, seems to be entirely due to the caustic effect of its alkalinity, as the same experiment, performed with neutral salts of nicotin, shows no effects. A piece of wet litmus paper held in the sidestream of smoke from the burning end of a cigarette turns deep blue, while one held in the mainstream of the smoke sucked through the tobacco shows no change or turns pink. Some of the irritation to the eyes and upper respiratory tract of bystanders may, perhaps, be due to the alkaline nicotin in the smoke from the sidestream of the cigarettes and cigars smoked, but in the acid mainstream smoke inhaled by the smokers themselves the nicotin would be mainly in the form of its salts, devoid of the irritating action of the base.

EXTRACTION OF NICOTIN FROM TOBACCO

It is chemically possible to extract nearly all of the nicotin from tobacco, but no commercial product so far examined even approximates this. Until some impartial authority, such as the American Medical Association, certifies that the final product actually contains less than, say, 0.2 per cent of nicotin, any one relying on the manufacturer's assurance is in danger of smoking more, and therefore absorbing more nicotin, than if he used the ordinary market brands. A truly denicotinized tobacco might indeed be a boon to sufferers from Buerger's disease, tobacco amblyopia, or other conditions ascribable to nicotin, but might produce as much local irritation as do the tobaccos with a higher nicotin content.

PYRIDIN

Besides nicotin, tobacco smoke may contain a number of other nitrogenous bases, chief of which is pyridin. Pyridin is more volatile and more irritating than nicotin, and may simulate many of its chemical and physiologic reactions. The claim that most of the nicotin in tobacco is converted into pyridin during the process of smoking,[9] however, could not be confirmed, as the heavy white crystalline precipitate obtained by treating smoke solutions with silicotungstic acid indicates that most of the nicotin in cigarette tobacco comes over unchanged in the smoke. The other alkaloids which have been reported in tobacco smoke are present in such small concentrations, according to the workers who have reported upon them, that it is very unlikely that they may be concerned in the local irritation.

AMMONIA

Ammonia may constitute, under some conditions, as much as one-half of one per cent of the smoke in the alkaline sidestream arising from the burning end of a cigarette or cigar, and this probably accounts for most of the irritation of the conjunctiva so noticeable in a small closed room in which much smoking is done. Owing to its absorption and precipitation in the acid stump of the cigarette, however, very little ammonia enters the mouth of the smoker through the mainstream of the smoke, and so this substance may not be held responsible for the effects of the smoke on the mucous membranes of the smoker himself.

OTHER CHEMICAL FACTORS

On the other hand, it is improbable that the small amounts of weak organic acids in the mainstream of the smoke are sufficient to produce any significant amount of local irritation, in spite of recent commercial insinuations.[10] The traces of hydrogen sulphid, methyl alcohol, cyanids, and other substances found only in minute amounts in the smoke may also be neglected. The carbon-monoxid content of cigarette smoke, which is greatest in the mainstream following fast and furious smoking, may perhaps be sufficient to account for some headaches or other systemic symptoms, but has no local effect that need be considered in this connection.

TARRY CONSTITUENTS

Some irritation from smoking has been ascribed to the physical effect of particles of matter in the smoke, tobacco, carbon, etc., acting inertly as material irritants. Special types of pipestems, cigarette holders and filters have been devised to hold back such particles, together with the so-called "tobacco tar" which settles out from the smoke. Chemical analysis indicates that such devices have little effect on the more important volatile constituents of the smoke, and clinical experience indicates that they are ineffective in eliminating irritation.

Although the tarry "tobacco yellow" may be esthetically disagreeable, staining the teeth and fingers, and giving an unpleasant taste and odor to the smoke, there is little evidence to suggest that it is actually irritating when freed of accompanying more volatile and soluble materials. The phenols, cresols, and other substances generally found associated with it may account, however, for a part of the irritation noted. The fact that these oily and tarry constituents of smoke have not been shown to possess high carcinogenic properties does not prove that they may not have other undesirable local or systemic effects.[11]

ALDEHYDS

The aldehyds produced in the course of combustion of tobacco are present in much greater concentration in the smoke from American tobaccos than in that from Oriental or West Indian cigarettes. Formaldehyd and acetaldehyd, which have been identified among them, are undoubtedly irritating, and the amount of aldehyd produced, if calculated as formaldehyd, would be in itself sufficient to account for a certain amount of local irritation. The reputed antiseptic properties of tobacco smoke, which have been subjected to repeated investigation with conflicting results, have been ascribed to the formaldehyd content of the smoke.

FURFURAL

Furfural has been singled out by Henry Ford[12] and others for especial attack, and in view of its known highly irritating properties, and its proved presence in the smoke, even though in minute amounts, it may not be disregarded. The fact that the aldehyds, including furfural, are found in lower concentration in the smoke from West Indian cigarettes, which are generally reported to be more irritating than the popular blends, however, demonstrates that the aldehyds do not, in themselves, represent the chief or only factor in the local irritation from cigarette smoke.

ACROLEIN

The irritating properties of acrolein, produced by the combustion of glycerin, were particularly emphasized by the late Thomas A. Edison. A small amount of acrolein may come from the native fats of tobacco, but more may be expected from the 2 or 3 per cent of glycerin which is added in the course of the manufacture of popular brands as a hygroscopic agent. How much of the glycerine present in tobacco is converted into acrolein has not yet been determined.

HYGROSCOPIC AGENTS

Aqueous solutions, through which cigarette smoke had been bubbled, were reported to cause edema of the conjunctiva of rabbits with all types of cigarettes studied; but those containing added glycerin produced a greater effect, and those to which diethylene glycol had been added instead gave less, than was noted from the smoke of plain cigarettes made without the addition of either of these hygroscopic agents.[13] It might be inferred that the addition of glycerin increases the amount of irritating acrolein in the smoke, while the absence of any hygroscopic agent leads to drying and consequently less absorption of other irritating substances in the stump of the cigarette. Other interpretations involving the technique of the experiments reported, possible chemical interactions between the hygroscopic agents or their combustion products and other irritating components of the smoke, and the pharmacologic action of these agents and their products, with particular reference to anesthetic or dehydrating effects, must be considered, and should be determined in future studies.

The clinical findings in a hundred smokers suffering from conditions attributed to irritation from the smoke, in most of whom the symptoms were reported to lessen or disappear with the use of cigarettes containing diethylene glycol as hygroscopic agent, and to return when glycerin-treated cigarettes were again used, appeared to give clinical confirmation to these claims.[14] Desultory inquiry among smokers, however, revealed quite contrary experiences. This study demands repetition on a larger scale, with the presentation of more detailed and objective observations, before the general validity of its findings may be established.

CIGARETTE PAPER

The common belief, that the products of the combustion of cigarette paper contribute an important part to the irritation from smoking, has led to repeated attempts at its elimination. The smoke produced by burning paper may be less pleasant and more irritating than that of tobacco, and in home-made cigarettes, unskillfully rolled with an extra twist of paper at the end, this may be noticed particularly in the sidestream smoke from the burning end of the cigarette immediately after lighting the cigarette. The actual amount of smoke produced by the burning of the paper in "tailor-made" cigarettes, however, is far too low to be of any consequence in this regard. Moreover, the products of the burning of the paper are, for the most part, removed from the smoke during its passage through the length of the cigarette before being inhaled.

The addition of nitrates or other materials to the paper or tobacco of cigarettes in order to promote combustion has been alleged. Investigations show most cigarette papers to be entirely free of nitrates,[15] while the nitrate content of the tobacco of various cigarettes is very low, averaging less than one-tenth of one per cent. This is less than found naturally in the dried leaves of tobacco grown with rich fertilizer, so it seems that cigarettes are generally not nitrated to enhance burning capacity.[8] The amount of nitrate naturally present in the tobacco, however, may contribute to the irritation from the acid mainstream of inhaled cigarette smoke, as well as, perhaps, to other systemic effects. The fact that the nitrate content is high in Porto Rican cigarettes, often reported irritating in spite of their low nicotin content, while it may be entirely lacking in Oriental cigarettes, makes this suggestion appear plausible.

ARSENIC AND OTHER AGENTS

The arsenic contained in the smoke from American tobaccos,[16] generally originating in the insecticides used on the plant, may be concerned in certain chronic skin lesions, but is in too low a concentration to cause local irritation or acute arsenical poisoning. Sugar or molasses, licorice, and similar foreign materials used in the manufacture of tobaccos, have not yet been shown to cause any increased irritation in the smoke. A host of adulterants, harmless or baneful, which have been suspected or even found in particular instances in the past, cannot be detected in standard brands of cigarettes.

SUMMARY

It appears from this rapid summary of the irritant factors in tobacco smoke that no single explanation applies to all of the phenomena observed. The irritation of the eyes of bystanders is mainly attributable to the ammonia and alkaline content of the smoke given off from the burning end, which are absent in that inhaled by the smoker. Heat, free nicotin, pyridin and other nitrogenous bases, volatile acids, tarry and phenolic substances and particularly the aldehyds liberated in the smoke, of which furfural and acrolein have been especially condemned, may all contribute to the irritation of the mucous membranes of the smoker.

Some individuals seem to relish the biting tang of the smoke as part of the pleasant sensory stimulation from a cigarette. More often this irritation is distinctly unwelcome. Although an occasional cigarette may do little or no harm, there seems to be little medical or scientific justification for the assurance reiterated in many advertisements that certain brands may be safely smoked absolutely without limit. May not the irritant factors in tobacco smoke constitute a natural safeguard, warning the individual against the excessive consumption of tobacco which might lead to more serious results from the absorption of nicotin and other toxic materials in the smoke?

DISCUSSION

C. H. Thienes, M. D. (University of Southern California, Los Angeles).—Wishful thinking and commercial interest have done more to befog the tobacco issue than scientific study can clear in many years. The almost universal use of tobacco forces the medical profession to give serious consideration to any dangers involved; yet the fact that the highest authorities in the land disagree among themselves over the many factors concerned, has made the average physician skeptical of any reports from research laboratories. It is interesting, however, that the official agencies of the medical profession, no less than the manufacturer, seem willing to profit from recent unconfirmed reports from well-known laboratories, in that large display advertisements are appearing in medical publications, even though the same organizations have councils and committees for keeping the drug manufacturer in the straight and narrow path. Certainly, in editorials and in reports of investigating committees and referees, the "denicotinized tobacco" myth has been discredited time and again, but on the basis of one recent experimental report, without waiting for confirmation, advertisements for "denicotinized tobacco" are being accepted.

Advertisements calling the attention of the physician to recent experiments on irritating properties of tobacco smoke are scarcely less objectionable; for, in publishing advertisements of that kind, the medical journal concurs in the suggestion that such experiments have been carried far enough to serve as a basis for the advice of patients by the medical practitioner.

Doctor Bogen's review has been so complete, and his logic so clear, that discussion of points in his paper would be superfluous. I heartily recommend that every physician who is advising patients concerning the use of tobacco keep Doctor Bogen's article close at hand for reference.

Joseph Goldstein, M. D. (727 West Seventh Street, Los Angeles).—It is interesting to note that Doctor Bogen believes the nicotin is not the most irritating factor, but that other volatile fumes are more harmful. The irritations arising from tobacco smoke are fairly well known, giving rise at times to serious conditions, and under such circumstances it may be recommended that the patient cease smoking entirely, such cessation often leading to abatement of the symptoms. Smokers' laryngitis, tracheitis, and pharyngitis are cured simply by withdrawing the irritating factors.

From published accounts of certain tobacco firms, one might be led to believe that their products were a cure for many ailments. Doctor Bogen's studies indicate otherwise.

NEW SIGN FOUND IN TRANSVERSE LESIONS OF SPINAL CORD*

By William J. Kerr, M.D.

and

C. A. Noble, Jr., M.D.

San Francisco

VASOMOTOR changes have long been utilized to supplement reflex and sensory changes in the localization of disease processes in the spinal cord. Similarly, disturbances in the function of sweating and in the erection of hair follicles, as well as unusual areas of pigmentation, have all been of distinct aid. As has been pointed out by Temple Fay and others, such abnormalities of the autonomic nervous system have often placed more accurately a disease of the cord, be that space-consuming, degenerative, or inflammatory, than the more commonly employed somatic sensory levels.

In 1930, the senior author first noticed in a patient with a somatic sensory level, due to a probable cord tumor, that there was a change of a different kind that could be felt. The skin above this level, which we may designate as normal, felt smooth, soft, moist, pliable, and could readily be lifted between the thumb and forefinger. On the other hand, the skin below the level seemed stiff, "hidebound," dry, and adherent to the subcutaneous layers, so that only with difficulty could a layer of skin be pinched together. It was found that this change could also be sensed by gently trying, with the tips of the extended fingers, to displace a segment of skin on its underlying tissues. Sometimes in patients subsequently studied the transition from normal to altered skin was abrupt, sometimes more gradual over one or two segments.

No reference to such a palpable level has been found in the literature, although this level may have a similar origin to the trophic disturbances and viscerosensory changes described by Pottenger. To describe the new sign we have used the term, "level of skin tension."

Since 1930 we have investigated about one hundred patients in the University of California Hospital and the San Francisco Hospital. The method of procedure has been for one of us to see the patient without knowledge of the location of a somatic sensory level, in fact, usually in ignorance of the presence of any such level. Then, in most cases, the patient has been seen independently by the other one of us, again in ignorance of those findings. Whenever feasible the examinations have been made with the patient both on his back and on his abdomen. Furthermore, the findings have been confirmed by later examinations when possible, and by correlation with other clinical studies supported by roentgen examination, anatomical details at the time of operation, or autopsy. Examination was found to be so confusing over the extremities that observations were made only on the trunk.

---

* From the Department of Medicine, University of California Medical School, San Francisco.

NORMAL CONTROLS

Sixty-four subjects in our group were examined presumably as normal controls. These were patients with various complaints, on the general medical wards of the University of California Hospital. In sixty-one of these sixty-four, changes in skin tension were found over the front or back. In the front there was an increased tension, as a band over the wall of the chest and upper abdomen, the width of which seemed to vary with the adiposity or extent of subcutaneous tissue present. The upper level of this band was just above, or just below, the nipple line, and would usually follow, not the configuration of the ribs, but would parallel lower margin of the thorax. In four cases, for reasons not entirely clear, the upper border of this band of tension reached the T2 segment. Two of these four patients were unusually obese. The lower margin of this band of hypertonus could be felt at a varying distance below the rib-cage, and in some cases extended to the level of the umbilicus. Occasionally the tissue overlying the sheath of the rectus all the way to the pubis seemed to be under increased tension. Below the lower level of the increased skin tension the skin again felt normal.

Over the back the normal controls all showed an area of increase in tension over the lower part, beginning at T8 or T9 segment and extending over the lumbar aponeurosis. In nine patients this level of increased tonus began at a slightly higher level, as high as T5 segment, again for reasons not quite clear. In three patients of our sixty-four control group, no apparent change in skin tension could be demonstrated, either on the front or back. It was noted, further, that where levels of skin tension were found in presumably normal controls, there were no associated pilomotor, vasomotor, or sweating levels.

GROUP WITH TRANSVERSE LESION OF CORD

There were twenty patients with a somatic sensory level and other convincing evidence of disease of the spinal cord. Their diagnoses included both intra- and extramedullary tumors, transverse myelitis of degenerative or inflammatory origin, diffuse arachnoiditis, and fracture of the spine. In these patients a level of skin tension was found which was in fairly close agreement, either with that somatic sensory level or, more often, with a level of change in sweating or pilomotor response. In ten of these twenty patients the level of the process in the cord was confirmed by operation or autopsy or, in the case of spinal fracture, by roentgen examination. In nine of these ten the level of skin tension corresponded exactly with the area of disease, and in one case pointed to a tumor five segments higher in the cord than indicated by the somatic sensory level. In this patient, whose first laminectomy had ended in a fruitless search for the lesion, operation confirmed the suggestion of a higher level of skin tension.

In ten patients with evidence of disease of the spinal cord with a somatic sensory level, no level of skin tension could be demonstrated. In four of these the disease process was in the spine below the lower level of the cord or the cauda equina.

In one patient there was a level of tension, but no other evidence of disease of the cord except for a congenital anomaly of the spine.

That this sign might affect the halves of the body differently is shown by two patients. In one of these patients there was a unilateral hypertonus of the skin, associated with marked constriction of the peripheral vessels on the same side, secondary to a cerebral lesion in the opposite hemisphere. The remarkable features of this case will be reported independently. A similar observation was made in a patient with a nearly complete Brown-Sequard syndrome, due to a fracture of the cervical spine.

What the physiologic disturbance is which underlies this change in skin tension must at present remain speculative. The close correlation between this sign and disturbances in erection of hair follicles, and in sweating, suggest that here we have another manifestation of innervation by the autonomic nervous system. We know, from the work of Beattie, Brow and Long, and others, that sympathetic fibers course down the spinal column in the lateral part of the ventral white matter in close relation to the vestibulo-spinal tract, and that they form frequent synaptic relations with cells in the lateral horns of the gray matter. From there they emerge with the anterior roots, the white rami, and then travel up and down the sympathetic chain sometimes several ganglia before making their synaptic connections with the last neurone. The last neurone, or rather those end neurones which affect the skin, reach the mixed somatic nerves via the gray rami, and then follow a segmental distribution. The wide overlapping known to exist in certain fibers of the sympathetic system may account for some of the discrepancies in our findings. It is conceivable that the altered skin tension is merely a sign of disturbed innervation of all the smooth muscles in the skin and subcutaneous tissues.

Too many of the tests at our disposal depend on the subjective impressions of what may be a comatose, a foreign, or a moronic patient. Any objective test which aids in localizing a pathologic process of the spinal cord would be of value. With that in mind, the level of skin tension is herewith reported.

University of California Medical School.

MEDITATIONS ON SOME PRESENT-DAY MEDICAL PROBLEMS*

By Alfred C. Siefert, M.D.
Oakland

To speak the truth and to shoot straight with bow and arrow, Zarathustra taught the young men of ancient Persia. These were considered manly virtues. Let us, then, select our targets.

The seal of Stanford University in my student years showed a giant sequoia and bore the words inscribed, "Die Luft der Freiheit weht." Later this inscription was changed to "Semper virens." Those who changed it did not know that growth and strength and evergreeness are possible only where freedom's breezes blow, yea where there are storms of freedom. Apply this to the profession of medicine.

A MARXIAN DOCTRINE

One hears so much how medicine must be socialized, communized, and enslaved, for the sake of humanity. A great institution of scientific achievement, a noble tradition of sympathetic helpfulness and strength to be torn down and disintegrated from within to benefit the weak and disinherited and the poor in spirit. Truly, Marxian doctrine, a sword that cuts both ways.

The decadence of our civilization and of our own people has progressed so far that the one thing we demand is "security." Government aid, relief, dole, Townsend plan—in short, we are ready for *panem et circenses* (food and motion pictures) free.

Once we asked for opportunity only, but now meet the vicissitudes of fate by insurance against this and that, and by this and that from the League of Nations to hospital service, nay, medical service insurance.

SCIENTIFIC STANDARDS IN MEDICINE MUST BE MAINTAINED

Government and State medicine may be inevitable. They will indeed be if the medical profession continues to offer compromises. Perhaps the majority sincerely believe that compromise is the only way to make bearable the unavoidable yoke. Would it not be better to accept battle, for to resign one's self without a struggle against that which the spirit rebels is craven.

THE MULTITUDE OF HOSPITALIZATION AND MEDICAL SERVICE POLICIES

Hospital insurance and group health insurance, and as many other types of insurance for which legal advisers can devise the proper terminology, are the order of the day.

Policies of nearly all of them are not sufficiently attractive unless "technical" or other roentgenology and pathology are included. Roentgenology and pathology are the worms that bait the hook; rhinology and obstetrics await their turn, and the entire practice of medicine, when the process will have progressed to its logical and unavoidable conclusion. Meanwhile the worms wriggle—it may be that pathology is already dead. Meanwhile houses of delegates pass resolutions and committees take vigorous stands, and attorneys-general hand down decisions. Let us be grateful to them all, but continue to wriggle.

"In the shadow of your swords, there let your paradise be."

THE FUTURE OF RADIOLOGY

Radiology, an "ancillary branch of medicine"—what are we to expect for the future of our science? Ancilla, a handmaiden. Radiology, a handmaiden. Radiologists, handmaidens. What young man of intellect and spirit will in the future select so menial a career? It hardly seems possible that medical leaders and hospital executives cannot see beyond the tip of their noses. "Take no thought of the morrow!"

We are being told by our own College of Radiology that we must raise the level of our specialty by education and training. This is excellent advice, provided that the contemplation of a contented cow in a hospital or government stable will prove to be sufficient inspiration.

What are knowledge and learning without character?

In the older roentgenologic treatises on the vertebral column we read about "intervertebral spaces." Let us fill in these spaces with tough annuli fibrosi and resilient nuclei pulposi to form a real *backbone*. A good head and a firm backbone are the needs of radiologists, today, beyond all other things.

RADIOLOGISTS SHOULD NOT HAVE PREFERENTIAL TREATMENT

Why should every incipient radiologist have a lucrative hospital job thrown into his lap?

What of the young practitioner of medicine and surgery, must he not fight and possibly even starve his way to success? Is not, perhaps, the complaint that the radiologist is not treated on terms of equality due to the fact that he has not won his spurs in this struggle of the survival of the fittest? Why do so many radiologists act like lackeys?

Rights and privileges are won by conquest. To be a peer among peers is a matter of confidence in one's self, and not of certificates and diplomas nor of condescension by anyone. Let us develop a little pride in our achievements.

RADIOLOGISTS SHOULD BE PHYSICIANS FIRST

"Too many radiologists contact only the patient's films, not the patient himself," says Edward Chamberlain very correctly. Let us remember that we are physicians first and foremost, and secondarily, specialists in radiology. Action upon that advice will contribute much to professional success and economic security. The point of the pen will not then be able to overthrow you.

Practice clinical radiology.

Why are we radiologists so squeamish about accepting responsibility? That is what makes many of us "glorified technicians." Many of our medical confrères do not hesitate to practice "amateur radiology" and take the responsibility. Let us develop at least an "amateur interest" in clinical medicine.

---

* Chairman's address before the Radiology Section of the California Medical Association, at the sixty-fifth annual session, Coronado, May 25 to 28, 1936.

Do not throw a patient out of your office because he comes to you directly without a written request for a "flat plate" of this or that. Advise him and refer him to the one among your medical and surgical confrères whom you consider the most competent to handle his case, and do not ask the doctor to limit himself to percussion or auscultation only in making his examination. It is more blessed to give than to be continually receiving, and you will be more respected.

Do not be a "hedger,"—God Almighty hates one; express an opinion, make a suggestion. Your consultant wants someone who will share responsibility with him, not shirk it.

IN CONCLUSION

The targets are numerous, but the quiver grows empty. Let us speed one last arrow on its way—its name, "In Unitate Robur" ("In union there is strength"). Remember the fable of Æsop about the father of seven sons who, by their constant dissension seriously impaired the standing and fortune of the family? The father one day called them together and requested each one in turn to break a bundle of seven rods. Not one of the brothers could muster enough strength to accomplish the feat. Then the father untied the cord that bound the rods together and easily broke each individual rod. The continuance of the Section on Radiology is more important to its members than they think. Let everyone help.

Have I struck my target?

411 Thirtieth Street.

THE MANAGEMENT OF ALCOHOLISM*

By Harry H. Wilson, M.D.
Los Angeles

Discussion *by John B. Doyle, M.D., Los Angeles; H. Douglas Eaton, M.D., Los Angeles; Aaron J. Rosanoff, M.D., Los Angeles.*

A BETTER understanding of the biochemical, sociological, and psychological factors involved in alcoholism is desirable, and is the incentive for this paper.

For the past several years there seems to be an increase in the frequency of medical contact with those who constantly use alcohol to such an extent that it interferes with their business, marital, or social life, or with those who are periodically so addicted as to present a grave problem.

The medical profession must not assume an acquiescent attitude; we are concerned with the responsibility of not only rendering skillful scientific assistance in meeting the problem of the individual, but of properly evaluating the injurious effects of the excessive use or abuse of alcohol upon the community welfare. The medical profession, in times past, apparently has been negligent in meeting its responsibility by the lack of an attitude toward the overuse of tobacco and understanding the importance of certain occupational diseases, with the result that non-medical workers have led the way in finding solutions of these problems. Are we to do the same with alcoholism?

In the past most physicians have been compelled to resort to the use of sedatives or the depressive type of treatment, which consists in the use of apomorphin, bromids, chloral hydrate, morphin, phenobarbital, etc., and the forcing of alcohol upon the patient's consciousness with the idea of producing nausea and an abhorrence that makes the thought of alcohol intolerable. These procedures have, however, only a temporary restraining influence. Physiotherapy, consisting largely of hydrotherapy, with the idea of washing out the patient and literally pummeling him into nonresistance, has a similar temporary value.

THEORETICAL CONSIDERATIONS

It is most important to determine what is and why is an alcoholic. In the years past it was held, and some still hold to the theory, that a chemical affinity develops between the cells of the body and alcohol, and that a cell hunger exists which only can be satisfied by the administration of alcohol; that this chemical hunger supersedes will power and all other factors involved. However, most contributors to the literature of today express the thought that alcohol is only a substitute used in the seeking of relief by a maladjusted personality, and each author presents his interpretation and classification of the various types of broken personalities. Most of us are familiar with the classifications of Freud, Adler, Jung, Du Bois, Ellis, Hart, Cowels, Watson, etc.

PRINCIPLES IN THIS DISCUSSION

From the standpoint of the internist or the family physician, it seems inadvisable in this paper to discuss in detail the various theories concerning broken or maladjusted personalities, but to confine the discussion to a few generally accepted principles:

1. We may assume that the type of individual who misuses and abuses alcohol will find a substitute if alcohol is unobtainable, for the energy of his mental complexes is bound to find an outlet.
2. Alcohol is usually an expression of a weak or unstable nervous system, rather than the sole cause of it.
3. The maladjusted individual will not reach adjustment by or without the use of alcohol, but rather will be harmed by its effects.

THE CLASSIFICATION USED BY THE AUTHOR

In approaching the individual problems, the author has started with the premise that "Life is a series of conflicts between personality and changing circumstances."

Now, what is personality?

It is the accumulative experience derived from tribal, racial, national, religious, familial, adolescent and personal heritage and relationships, with a result as if all these factors formed a mold or an iron helmet into which the ego was poured, each impression leaving an indelible mark to shape the personality or ego of the individual.

---

* Read before the General Medicine Section of the California Medical Association, at the sixty-fifth annual session, Coronado, May 25 to 28, 1936.

RESULTS OF THE CONFLICT BETWEEN PERSONALITY AND CHANGING CIRCUMSTANCES

1. The normal is exemplified by one who recognizes values and understands that it is relatively unimportant what happens to him, but that it is very important how he behaves toward what happens to him. In other words, the importance of attitude and behavior is understood; the ability to properly evaluate maintains throughout life.

2. The Attempted Adjustment or Maladjusted Group. This group consists of those who fail in the conflict to maintain a sense of values; and the first subdivision and the largest in number consists of

(a) *The Neurotic.* We are all familiar with the frequency with which symptoms are substituted for failure; this individual, as a defense mechanism, to excuse his or her failures or frustrations, uses illness which permits the justification of ego, and therefore substitutes symptoms for understanding.

(b) *The Genius or Work Substitute Adjustment Group.* This group, much smaller in number, consists of those fortunates who have literally thrown their nervous energy into a selected field of endeavor, with the result that they have so occupied their nervous energy as to permit it to act as a narcotic to obscure the importance of the sense of failure which brought about the maladjustment originally.

(c) *The Religious Zealot.* Here we have a substitution of faith for thinking. Here the inability to evaluate on the basis of logic permits the placing of an all-abiding confidence in a Greater Force as a reason for all of the apparent injustices of life, which are being worked out, and eventually reparation will be made by this Great Unseen Force. It is fortunate indeed for mankind that faith exists.

(d) *Drug Addicts.* The use of narcosis to inflate the ego or depress the veneer of culture and civilization is so well known and so closely allied to alcoholism as to permit its being considered in the same classification as (*e*) the liquor addict.

(e) *Alcohol Weaklings or Addicts.* The susceptibility of man to alcohol is variable. In its mild usage it may appear to be a blessing. Bernard Shaw states "that the common lot of the workingman in England is so hard, with his lack of education, lack of cultural development, too early marriage, too many children, inadequate income, long working hours, supervised by a dominant boss, going home where a shrew of a wife berates him for his inability to provide things that the more fortunate Mrs. Jones has, leaves a man with his ego so deflated that he finds solace in drink for a few hours in which he thinks himself a king."

This illustration seems to be nearly the only justification for the use of alcohol. The higher degrees of intoxication which permit the maladjusted personality to try to crawl into the neck of a bottle to hide from his problems in narcosis is the usual problem which confronts the family doctor.

(f) *Psychosis Group.* The last group in my classification of broken or attempted adjustments consists in the suicides, criminals, and the more or less completely broken personalities, many of whom are classified as insane, some called dementia praeçox, others the depressive types of melancholia, etc. A considerable number of these may be corrected by proper understanding.

INVESTIGATIONS ON ABSORPTION OF ALCOHOL

Turner, Bogen, and others have proved:

1. That the rate of absorption of alcohol in the various tissues is practically the same.

2. That the degree of absorption of alcohol in all tissue cells, chiefly the brain, liver and kidney, is almost identical.

3. That blood alcohol determinations evidence that alcohol is practically eliminated from the blood stream in twenty-four hours.

4. That the blood alcohol content is in direct proportion to the degree of intoxication.

In my own experience, based upon a chance observation that several patients recovering from the abuse of alcohol had many symptoms similar to those of hypoglycemia or hyperinsulinism, blood-sugar studies were made and in every instance there was a rather constant finding of approximately 60 to 70 milligrams of sugar to 100 cubic centimeters of blood. It is a well-known fact that hypoglycemia follows poisoning by such drugs as carbon tetrachlorid, chloroform, guanidin, etc., by retarding glycogenesis in the liver, and that the liver has the bulk of work in handling alcohol; that overloading of the liver by alcohol retards glycogenesis; that at the same time the constant or excessive use of alcohol produces an excessive insulin secretion. It is readily understood, then, that the after-effects of alcoholism may be largely attributable to the overloading of the liver, the overactivity of the pancreas and their failure to assist in taking care of the alcohol, resulting in the production of nausea, tremor, vasodilatation, excessive perspiration, mental depression, etc.

It was the result of these observations which caused me to refrain from the commonly used depressive type of "knocking out" a patient by sedatives, and to substitute a supportive type of treatment.

TREATMENT OR MANAGEMENT

The treatment is divided into two definite phases: first, the biochemical; second, the psychologic. Naturally, they overlap.

An injection of colloidal calcium and dextrose is given two to four times daily for approximately three days, for the purpose of obtaining an improvement in glycogenesis, combating hypoglycemia, with the prevention of the accumulation of lactic acid in the tissues. It also relieves the headache, markedly controls tremor, and (where tests have been made) the blood-sugar level rises. In addition, general hygiene measures are instituted together with specific therapy, dependent upon the findings arrived at as the result of a careful history and physical examination.

This procedure accomplishes several things:

First: The patient must report to the physician two or three times each twenty-four hours, and in a condition of sobriety.

Second: A definite program has been instituted in which the patient's confidence must be obtained.

Third: It permits of the opportunity for closer acquaintanceship, with the gradual working out of the reasons for maladjustment under conditions which allow the patient to freely give his confidence to the physician.

Fourth: Each patient has obtained tremendous physical support with great alleviation of the symptoms of the "hangover," and the calcium and dextrose appear to take away the overwhelming desire for another drink, which so frequently obtains in the confirmed alcoholic. After a few days, when the patient is feeling physically well and mentally better, and does not hold such a morbid viewpoint concerning himself, and is beginning to look to his physician with a sense of respect and confidence, a careful presentation of the psychologic factors of maladjustment is made.

This, of course, is the most important part of the management of alcoholism, and success or failure is dependent upon the understanding of the physician and his ability to express himself clearly, simply, and in a manner comprehensible to the individual being dealt with. I wish to stress the importance of not overestimating the patient's intelligence or knowledge, and the need for avoiding confusing terminology, and the necessity of confining the discussion to factors that pertain to the patient's life, which have been brought out in the preliminary discussions and may be easily recognized by the patient. This whole approach is an attempt on the part of the physician to supply an abbreviated psychoanalytical study, and its importance cannot be overstressed.

FACTORS TO BE CONSIDERED IN DIAGNOSIS

In my own contacts I have attempted to arrive at a tentative diagnosis as a result of the observations made during the preliminary supportive phase of the treatment, stressing three factors:

1. Is the degree of alcoholism such as to leave the will still predominant?
2. Has it reached a stage where it has affected the veneer of culture or civilization?
3. Is the degree of alcoholism an expression of a hereditary degenerative type?

I am frank to confess that I have felt competent to approach only the first two phases, and that the limits of my understanding of the psychologic factors have prohibited me from attempting to deal with the most severe stage of maladjustment.

One other determining factor is: Does the patient have an incentive or anchor that gives him something to work with? I mean by this the need or desire to support a family that he loves, an abiding faith, etc. For without an incentive on the part of the patient there is little desire on the part of the physician, because the effort involved in working out these problems is great, and the time consumed must be considered, for most of us dislike wasting time and energy where the promise of results seem so slight.

I use graphic illustrations to explain to the patient how he acquired the maladjustment in his personality, and how it was caused by his failure to adjust to changing circumstances; where alcohol entered into the picture as a substitute for understanding, and how one must substitute work, love, play, and faith, or reëstablish a sense of values which puts him back into the normal class to obtain permanence in the abstinence from liquor.

IN CONCLUSION

An analysis of some ninety-odd cases that form the basis for this paper indicates that the greatest success follows where the use of alcohol is occasioned by falling into the error of social drinking, with the failure of the individual to understand that he has become a victim of a common physiologic factor: the ease with which impulses make use of the association fibers, so that these individuals who fall into the habit of taking a drink under certain circumstances or conditions gradually drink excessively until it takes the place of reasoning, or they reach the stage where the pathologic effects of maladjustment have become relatively fixed. With these people who fall in the first degree of intoxication, the will is still predominant, the incentive or anchor present, and when an explanation is made and an understanding is arrived at, the cure is relatively simple and assured.

The second degree of intoxication offers more difficulties, because the individual has become pathologic, is a liar, completely untrustworthy, cheats and steals even from himself, has lost incentive and self-respect. Success in this field follows only where strong supportive factors are present.

The third stage, in my mind, is almost entirely the problem of the psychiatrist or neurologist, and requires institutional care, the hope of rehabilitation being slight.

1919 Wilshire Boulevard.

DISCUSSION

John B. Doyle, M. D. (1930 Wilshire Boulevard, Los Angeles).—Doctor Wilson's observations concerning the resemblance of the more severe symptoms of alcoholism, and those of hypoglycemia or hyperinsulinism, are very interesting. For many years I have felt that some of the more profound disturbances, such as delirium, were due to quantitative and qualitative starvation. Accordingly, I have prescribed hot milk and cream, liberally seasoned with powdered capsicum, and fruit juices on alternate hours. More recently a concentrate of vitamin B has also been employed. When sedation has been required, paraldehyd has usually proved adequate. Spinal puncture is indicated when agitation is more marked than usual.

The problem of alcoholism is the problem of addiction in general. It is only the cultural characteristics of nations which determine that opium and its derivatives shall be the dominant addiction of the Orient, and alcohol of the Western World. While it is probably true that only individuals possessing a certain innate peculiarity become addicted to depressants, with the effects of which they are acquainted, it seems certain from clinical experience that, until the span of life is complete, predictions as to the presence or absence of this quality cannot safely be made.

⁂

H. Douglas Eaton, M. D. (1136 West Sixth Street, Los Angeles).—Alcoholism is a problem with which all physicians, whatever their specialty may be, are brought into contact. The existence and growth of quasi scientific and commercialized, so-called "cures," demonstrate both the difficulty of the problem and the inadequacy of scientific medicine in meeting it. Those of us who, through a lack of interest or knowledge, do not wish to handle the therapy of alcoholism ourselves should at least be prepared to advise in general terms and to steer the alcoholic into competent medical hands.

Doctor Wilson's approach to the alcoholic problem is an interesting and stimulating one. Certainly any adequate therapy of alcoholic addiction must take into consideration the personality of the addict, as well as the chemical and pathologic changes that are present in varying degrees. Treatment aimed at the elimination of the last-named factors rightly initiates our handling of the individual case. Doctor Wilson's suggestions along this line merit further observation and study in a larger series of cases.

The subject of individual maladjustments and personality disorders is too broad to be covered in the present discussion. We can agree with Doctor Wilson that success in the handling of such cases depends on an adequate analysis of the individual case, followed by reëducation, both mental and physical. Such treatment offers the best, indeed the only, chance of permanent cure, and undoubtedly succeeds in a percentage of the milder cases of alcoholism.

The truly pathologic type of alcoholism eventually falls into the hands of the neuropsychiatrist and is, in my experience, one of the most difficult problems he is called upon to meet. Here one is confronted not only with lack of coöperation on the part of patients—a large majority of whom consult us, not because of their own desires, but because relatives or friends insist upon it—but frequently with actual inadequacies in constitutional make-up and definite psychoses. In another group, despite a potentially normal make-up, the chemical and pathologic changes mentioned by Doctor Wilson have become irreversible rather than reversible. In such cases a controlled environment, often for a considerable period of time, is requisite for successful treatment.

Doctor Wilson has outlined a viewpoint and method of approach to the problem of alcoholism which should prove of definite value to every internist dealing with these cases.

⁂

Aaron J. Rosanoff, M. D. (1908 Wilshire Boulevard, Los Angeles).—A rather pessimistic note is to be detected in Doctor Wilson's paper, especially with reference to the more severe types of cases of chronic alcoholism. In my opinion this is justified by many discouraging experiences.

Millions of people drink, yet only thousands become chronic alcoholics. It is obvious that the nature of the soil is an important factor in etiology. To what extent this is inborn and to what extent this originates in social environment is a question that no one could answer fully, but undoubtedly both inborn and environmental factors combine to produce the phenomenon of chronic alcoholism in a small percentage of individuals.

I have had an opportunity of discussing with Doctor Wilson the special plan of treatment which he has outlined in this paper. I have had no personal experience with it; but I have witnessed the trial of this treatment in three cases which I had had under my care. The results were unsatisfactory, both while under my care and while under the treatment described by Doctor Wilson.

In an experience extending over a third of a century with more than two thousand cases of chronic alcoholism, I, too, have come to be pessimistic about the prognosis. I believe there is no such thing as a cure for chronic alcoholism. It is true that about 10 or 15 per cent of the cases do recover, but such recovery in my experience is to be attributed not so much to the method of management as to a more than usually favorable soil in the temperamental make-up of the individual.

As alcoholism continues it invariably leads to further deterioration of temperament and character, and thus a vicious circle is established until a point is reached eventually when the prognosis becomes quite hopeless. In other words, something might be accomplished in a limited percentage of cases of recent origin, but hardly anything in cases of old standing.

Recently I had an occasion to review a Russian contribution on the subject of alcoholism (*American Journal of Psychiatry*, 92:992, January, 1936). Under the special conditions which now prevail in the Soviet Union, real success on a large scale has been attained in the management of alcoholism. Drunkenness, acute and chronic, has always been a vast problem in the Russian Empire. I doubt if anything of practical value is to be gained here from a study of the management of this situation as it is organized in the Soviet Union today; their methods could not be applied in this country.

THE LURE OF MEDICAL HISTORY[†]

CALIFORNIA'S FIRST MEDICAL SURVEY: REPORT OF SURGEON-GENERAL JOSÉ BENITES[*]

A TRANSLATION[‡]

By Sherburne F. Cook, Ph.D.
Berkeley

In 1804, the surgeon-general at Monterey, José Benites, was called upon by the Viceroy to make a report on the state of health of the whites and Indians in the California settlements. This report, or "Informe," forwarded under the date of January 1, 1805, has been frequently mentioned by persons writing on California medical history, and small portions were translated by Father Zephyrin Engelhardt.[1]

However, the complete document has never been translated, nor have the comments and criticisms of the royal director of the treasury and the Royal Medical Board ever received attention. These, in themselves, throw valuable sidelights upon the status of the medical profession and public health in the early nineteenth century. All three documents are to be found as copies in the Santa Barbara Archives, Vol. 3, pp. 4-12, as they are at present bound in the Bancroft Library, Berkeley.

[†] A Twenty-Five Years Ago column, made up of excerpts from the official journal of the California Medical Association of twenty-five years ago, is printed in each issue of California and Western Medicine. The column is one of the regular features of the Miscellany department, and its page number will be found on the front cover.

[*] From the Division of Physiology, University of California Medical School, Berkeley.

[‡] Editor's Note.—Where and how the author found this interesting original report is stated in the following letter:

To the Editor:—Not long ago, while looking over the Santa Barbara archives, I came upon the original Benites report of 1805, together with two other related documents. Since this was the first comprehensive report ever rendered by a physician concerning the state of health of the inhabitants of this State, and since it has never appeared as a whole in print, I have translated it, together with the comments of the Royal Treasurer and the Royal Medical Board of Mexico City. I may add that the report contains what, as far as I am aware, are the earliest case histories from the State as described by the attending physician.

Thinking that these documents might possibly be of interest to the medical profession of the State, I am forwarding translations herewith, submitting them for publication, if you think desirable, in California and Western Medicine.

Very truly yours,
S. F. Cook.

REPORT OF SURGEON-GENERAL JOSÉ BENITES

Benites' report is as follows:

Monterey, Jan. 1, 1805.

Your Excellency:

I am complying with the superior order sent by the kindness of your Excellency for the betterment of humanity, dated September 4, 1804, which has been given to me by the Governor, Don José Joaquin de Arrillaga, that I should report on the various illnesses which I have observed and their causes. I state they are the following:

First syphilis, or French malady (morbo galico); humid climate with continuous heavy fogs, and great cold. The causes of the first are the use of polluted water employed for all preparation of food, the lack of cleanliness in their homes due to disinclination toward such, their lack of space, and the presence of an estuary (inlet), near the Presidio, without communication to the sea except in the winter, and even then so stagnant that it spreads putrefaction, which is the origin of diseases. The waste water from the laundry, which is located about four varas (yards) from the above-mentioned estuary, serves for the preparation of food, good water being a league and a half distant. The infrequent use of vegetables, or lack of taste for them; the constant exposure of this people to the humidity, fogs and the rains in their season; and the frequent habit of drying their clothes on their bodies by natural and artificial heat are causes for corruption.

The second I ascribe to the first cause.[2] The third, although not very frequent, is produced by the excessive cold, which in suppressing perspiration is cause of a congestion about the lungs when they themselves are exposed to the effect of the cold. This happens much more when inflammatory sciatica prevails, due to overexertion and loss of sleep. This I observed from the tenth of September, 1803, until the middle of January, 1804, during which time the winter was very severe and rainy. They all (the sick) recovered due to my assistance, except a sexagenarian whose name was José Soberanes, a retired soldier of this company, in whom at my arrival the pneumonia or inflammation of the chest of which he suffered had terminated as gangrene and caused his death, in spite of the treatment given him to alleviate the terrible progress of the inflammation. Xavier Avila, a soldier of the above-mentioned company, suffered from a dysentery for two months. I assisted him with the most efficacious medicines which I have at my disposal, and according to the precepts of the most learned authorities, and succeeded in restoring his health to the point where he was able to go across the plaza; and I advised him to follow a reasonable diet. But paying attention neither to my advice nor his own discomfort, he gave himself up to eating foods hard to digest, and in a few days suffered a relapse of the same illness, only this time more severe than the first attack. I gave him the same medicines as I have stated above. Paying no attention to the weak state in which he found himself, he continued with his excesses, repeatedly arising from his bed, sitting by the hearth, or fireplace, which they use in their kitchens, eating beans and chili, and not minding the entreaties and appeals by which I tried to make him realize how serious his situation was, and how imminent his danger of death. I had the honor of visiting him with the most Rev. Father Fray Antonio Jayme, and we found him by the above-mentioned hearth, on the damp floor (as all these houses are) eating entrails, or tripe, fried in the embers, as is the inveterate habit of all of them (the soldiers). This immoderation, and those above mentioned, caused his death on the twenty-fourth of December of last year.

Since then I have observed two patients with pleurisy, one of twenty-four years of age, and a girl with dysentery, three years old; all these now enjoy perfect health. Maria Dolores Cantua, in consequence of a difficult delivery and of a hard deposit formed in the abdominal viscera, died after twelve days from secondary effects of the parturition. During this period there have been a few wounds in the service, some serious and others which have been cured perfectly.

Your Excellency, in this place, in order to further the comfort and nurse the illnesses of the troops and neighbors of this Presidio, and of others, it would be good if we had a room[3] to help them. Hitherto, for lack of this and other equipment, many of them have had to be abandoned, to sleep in their homes in one bed with their wives, not having another, from which results spreading of diseases and detriment to the Royal Service. Also the unmarried men in the Presidio are left by themselves in the hands of their own kind. All this I call to the attention of the kindness of your Excellency that you may make disposition according to your superior pleasure.

Having gone out by order of the provisional commandant, Don José Antonio de la Guerra y Noriega, to help the Reverend Fathers in the mission of La Soledad, at the request of said Fathers, I investigated and observed among their neophytes syphilis, pleurisy, inflammatory fevers, and a climate foggy and windy in the extreme. In the mission of San Antonio, under the right Reverend Father Marcelino Sipres, I observed tuberculosis in its different stages, and also syphilis. In San Juan Miguel, where I stayed two days at the request of the Right Reverend Father Fray Juan Martinez, I observed dysentery; and according to the report of that clergyman, who with real interest asked me for help for his neophytes, I know that this illness is still in progress. The climate of this mission is the same as that of San Antonio, for both are subject to seasonal extremes of heat and cold.

In the mission of San Luis (Obispo), at the request of the Reverend Father Fray Luis Martinez, in a hospital which he has for his neophytes, in which I found about thirty patients, the greater part being women, I found tuberculosis and syphilis in the highest degree, and the Father informed me there were many more who suffered of the same disease. Nevertheless, I did my best during the ten days I was there. In the mission of San Carlos, which I have visited several times, I have seen several of its neophytes, the majority of whom had scrofula. On the way to San Francisco to treat the Commandant of that Presidio, in the mission Dolores I found much scrofula, syphilis, and a moderate climate. In the mission of San Juan Bautista (there were) syphilis, some tuberculosis and a windy, cold and foggy climate.

The causes of these diseases are: impure relations on an excessive scale, the great filthiness of their bodies and villages, direct and indirect contact, the sick sleeping with the healthy ones, the custom of frequently exchanging clothes, the loss of sleep during their games and dances, in which games and dances they all sing, reinforcing by movements (of their bodies) the organs of respiration; the depraved use of a sweat-house (temescal), made in the center of earth, around the circumference of which can lie at least twelve [persons] who enter by a little door and force themselves to sweat by a fire. Since these sweat-houses are always located near a fountain or pool, they come out of the warmth and jump in the cold water. To these indiscretions, which I have seen, and others of which I have been told, are due the diseases mentioned, and in spite of the charitable zeal of the Reverend Fathers in taking me to their villages that I might apply to them some medicines, to such an extent reaches their barbarism that they prefer to believe others who tell them that the Father is killing them. Scorning this help (that of the priest and physician), they doctor themselves by washing their sores or wounds, and scarifying themselves with flints, even to the eyelids, whatever the sickness is, not to mention other atrocities which they perpetrate.

If it should be pleasing to your Excellency, in your great charity, that I may go to the other missions and the Presidios of the Channel [Santa Barbara] and San

---

[2] The text here is ambiguous. *La segunda* and *la tercera* may refer to a list of diseases of which the first, syphilis, has already been discussed. However, no such list appears. On the other hand, they may refer to the "humid climate" and the "great cold" respectively. If this is true, a confusion appears to exist in Benites' mind with respect to cause and effect between these natural phenomena, and the diseases he associates with them. The translation is quite literal at this point.

[3] *Una sala.* A room or hall to serve as a small hospital or infirmary.

Diego to examine the diseases of their neophytes, which I will observe with all the thoroughness which is granted me by God our Lord, and if the mercy of His Majesty, and of your Excellency orders me to do this for the good of humanity, then in the fulfillment of my duty and for the honor of my profession I shall do it. May God our Lord preserve your Excellency for many years.

(Signed) José Benites.

TRANSMITTAL LETTER OF OFFICER BORBON, FISCAL OF THE ROYAL TREASURY

Benites' statement was forwarded to the Fiscal, or the officer in charge of the Treasury, who usually commented on such reports, and made recommendations concerning their disposition. The Fiscal wrote as follows:

Mexico City, April 27, 1805.

Your Excellency:

The Fiscal of the Royal Treasury states that the governor of New California is sending to this high court the account or report which was sent to him by the surgeon of the Presidio of Monterey, Don José Benites, concerning the different sicknesses which he has been able to observe during his stay there and which the inhabitants suffer most frequently, stating that it would be advantageous to establish a "sala" or hospital where the troops and neighbors of the Presidio and others might be treated for their ailments with somewhat greater facility.

The object of such reports should be no other than (to make it possible) to adopt the most favorable and practicable measures for the welfare of humanity, either by completely destroying the contagiousness of some diseases, which have become almost indigenous to those countries, or, if this is not possible, to adopt measures to check their spread. Both purposes conform to the spirit of the Royal Decree of the 8th of November, 1797, which undertakes as far as possible to relieve and alleviate the distress of the Indians of Old California, and in harmony with which it was also decided to send to New California a physician with an adequate stipend. It is the opinion of the Fiscal that in order to achieve, in so far as possible, such desirable ends your Excellency should order that this communication be forwarded to the Royal Medical Board.[4] This is in order that, having become acquainted in detail with the report of Benites, it may point out the measures and regulations which by virtue of its practical and scientific knowledge it deems most likely to yield a system adapted to the climate and other qualities of the country as described by the afore-mentioned surgeon, with the object that, in accordance with the nature of circumstances as they arise, he may be able to put it into practice and use it according to the knowledge his experience there has given him. A proclamation of the decision made by the above-mentioned Board should be sent him through the governor with a provision that if his affairs should permit him, he might go to visit the missions and the Presidios of San Diego and the Channel in order to secure information concerning the diseases which are most common there and the most convenient means for the relief of the inhabitants. He should continue to send annually the accounts and reports required by the superior decree of September 4, ultimo.

Although the critical and pressing condition of the exchequer does not permit at present the establishment of a room or hospital as proposed by Benites, the emergency seems to the Fiscal adequate to warrant that your Excellency be pleased to order that when the Royal Medical Board has prepared its report, it having been sworn to and recorded, the report of Benites, and this reply, if it merits the acceptance of your Excellency, should be forwarded to the Illustrious Diocesan (the Bishop of Sonora). Then, after he has informed himself of the matter he may adopt, for such a meritorious and necessary purpose, those measures dictated by his notable pastoral zeal for the welfare of humanity and the aid of his spiritual subjects; communicating his decision to the said governor for his information.

(Signed) Borbon.

COMMENT OF THE ROYAL MEDICAL BOARD

This reply was approved by Viceroy Iturrigaray on May 3, 1805, and the report of Benites passed on by the Royal Medical Board. The latter considered the matter and returned the following statement:

Mexico City, May 10, 1805.

The diseases to which Don José Benites refers and which have been observed at the Presidio of Monterey, as well as at various missions visited by order of your Excellency, are common to the whole country and are seen among the entire population, for they are of the type that are caused by the disorders of the people or simply by the changes of season. Nothing can be argued against the climate of those provinces where there exists an endemic or regional debility except with respect to nutritional excesses and irregularities, and hitherto climates have been considered healthy when bad water, the estuaries, and other various causes of bad health have not produced the corresponding effects such as diseases of filth and relapsing fevers of which Benites makes no mention; nor are the diseases very numerous, for in one mission he saw only dysentery and in the others syphilis in advanced stages, and of considerable frequency.

No method can be devised which can spare the inhabitants the diseases which they suffer since the latter are due to inevitable causes and voluntary indiscretions; to the first belong the extreme cold, the lack of shelter, the bad water, lack of vegetables, and badly prepared meats; to the others belong carnal promiscuity, the mingling with infected persons, and the natural slovenliness of a people as yet little civilized, and who, in case of sickness, despise rational medicines, and use only the empirical treatment dispensed by their national doctors, each of which has knowledge only through his own experience.

Not only in those remote provinces is this the case, but even in our own country, and home. In the latest epidemic of smallpox, which occurred in Tacubaya (Mexico) where (I) was sent as doctor by the Regent Guebara with a supply of medicines to help them, the sick went into the back country and up to the hills to avoid being treated, and would go only to a medicine woman at Escapuralco. The same thing happened at San Salvador El Verde near Puebla, where some malignant fevers were detected and the commissioner, Don Ciriaco Carbajal, agreed with this Board in sending a physician to cure the sick, who, as soon as they learned that the professor had arrived, would hide themselves or deny their existence. This being understood, what can be expected of the inhabitants of California when those who are more enlightened resist rational treatment? The means of relieving the former could be administered by Benites, although not with all the breadth and skill of a professor of medicine, but the difficulty is that they may not follow his rules and that the salutary measures for their relief may be rendered useless.

There is no doubt that the establishment of an infirmary, into which the patients might be gathered, would facilitate their normal convalescence and be of the greatest assistance to Benites, but in addition to the difficulty pointed out by the Fiscal concerning its construction there is that of being able to get hold of the sick persons on account of the aversion they hold to such asylums. And, furthermore, there is the matter of accessory expenses such as arise in hospitals in connection with the administration of medicines and the care of the convalescents. If, actually, these obstacles could be overcome the establishment of an infirmary would be an advantage and help to those people, and it would be possible to alleviate principally syphilis, which, neglected and unattended, spreading by all the means of which it is capable, raises havoc with whole populations.

Understanding these things, your Excellency will adopt those measures which seem to your judgment best suited to the situation.

(Signed) José Vicuna, Muro.

CONVERSATIONAL GEMS OF DR. J. P. WIDNEY*

Founder of the Los Angeles County Medical Association: At Age of Ninety-Five Still Active in Literary and Church Work

It is not enough to read a good book—reread it and grow up with it.

A good book should be a friend—not a chance acquaintance.

Little Timothy ought to yield a good crop—he's been sown in good soil.

The danger to a republic comes when men begin to sink their patriotism in their personal interests and their prejudices.

The moment a man admits the working of the law of cause and effect he is not an atheist.

"Cut your coat according to your cloth." You cannot make a frock coat out of a jacket.

Do your duty faithfully and your reputation will take care of itself.

"It is the unexpected that happens." Guard against the thing that never happens.

Let your horizon line be broader than self.

French is an eye-language. It is a nimble language.

Don't throw away your bread because you can't have butter on it.

If you would live, have something to live for; a man does not die until his work is done.

It takes a warm heart to win warm friends.

Truth may be so told as to become a lie.

In music, the sharps have pathos and majesty—the flats are smooth and mellow, but commonplace.

(To be continued)

CLINICAL NOTES AND CASE REPORTS

UNUSUAL CASE OF FIBROMYOMA UTERI

By STANLEY E. COFFEY, M.D.
AND
ERMANELL C. COFFEY, M.D.
Orland

A SURVEY of the literature anent fibroids in general seems to indicate a pretty fair agreement that the incidence of these tumors in girls under the age of twenty is to be considered a rarity. It is with this idea in mind that we submit herewith the following case report, interesting, on the one hand, from the standpoint of the patient's age and, on the other, from the standpoint of differential diagnosis in this particular case.

Anspach[1] quotes that in forty-two cases, reported by Laudau and occurring between the age of twenty and thirty years, only two of the patients were twenty years old. C. C. Norris[2] quotes the statistics of Frank, Kelly and Cullen, McDonald and himself, comprising 3,091 cases, wherein it is shown that only 13.7 per cent of all cases occurred in the decade between twenty and thirty years, and that the youngest patient was twenty years of age. Lynch[3] relates that Pick, Anspach and himself have found them in new-born children, and that Gusserow and Tillaux described the tumors in girls of ten, fourteen, sixteen: three at the age of eighteen, and eight at nineteen years. Yet, in his own series of 683 operative cases, no patient was under the age of twenty years. Hence, it would appear that this condition existing in a girl of eighteen years is of sufficient interest to warrant reporting.

REPORT OF CASE

On February 7, 1936, we were called to attend Miss F. A., aet. eighteen, who had been ill for ten days prior to this visit.

Chief Complaint.—Bleeding of a menorrhagic type for ten days.

Personal History.—In August, 1936, the patient had been exposed to pregnancy. Two weeks later she developed a discharge and reported to a physician, who made a diagnosis of trichomonas vaginalis and for that successfully treated her. There was no further history of discharge of any kind. Menstrual periods remained regular and of usual duration. No intermenstrual bleeding. No further interesting history appears until late in December, when the patient noted movements in her pelvis and lower abdomen, had a short period of nausea without vomiting, and a mild frequency of urination. This disappeared in about two weeks. Late in January she noted a swelling in her lower abdomen in which she claimed she could feel movements. These she described as a light tapping sensation. Periods still normal. No further developments occurred until the onset of her chief complaint.

Family History.—M. d. eighteen years ago, six days after the patient was born, from postpartum eclampsia, as near as can be determined. F. l. and w., German peasant stock, aet. forty-eight. Only suggestive family history is that of maternal aunt, l. and w., operated twice for uterine fibromata. One half-sister, l. and w., aet. thirteen.

Examination.—Girl of stated age, in bed, with marked evidence of secondary anemia, in no apparent pain, but with profuse bleeding from uterus. Aside from mild acceleration of pulse to 110, and paling of conjunctivæ, positive physical findings were confined to the abdomen and pelvis. There appeared to be a definite mass, directly in the midline, which on palpation was round and smooth, but rather harder than the pregnant uterus. In size it was comparable to the head of about a five- to six-month fetus. There was no evidence of any other tumor masses. Vaginal examination revealed a hard mass in the posterior fornyx, rather harder than the pregnant uterus and without its usual doughy consistency. Visual examination with the speculum was impossible under the local conditions. No movements could be palpated. There was a marked bruit, but no evidence of fetal heart sounds.

Diagnosis.—Incomplete five- to six-month miscarriage; unruptured ectopic pregnancy; cystic ovary; dermoid cyst; atypical intramural fibroid.

Treatment.—Usual expectant treatment for incomplete abortion, *i. e.*, fluid extract of ergot in dram doses, six such doses. Bleeding was interrupted, but not entirely stopped. Uterus failed to empty its contents.

After forty-eight hours of observation, it was decided to intervene surgically. The patient was accordingly transferred to the hospital and prepared for both dilatation and curettage and laparotomy. Blood count revealed a relative leukocytosis of 10,500; red blood cells, 2,950,000; hemoglobin, 55 Talquist. General preoperative condition was fair.

The cervix appeared nulliparous, and almost entirely obliterated along the posterior wall by a large, round, smooth mass. The sound was directed anteriorly by the same mass, as was the dilator. Gentle curettement resulted in small amounts of endometrium, curiously similar to that found in ectopic pregnancy. Practically no bleeding accompanied the curettage.

Immediately following this exploration, a laparotomy was performed through a midline incision. The uterus was found to be well into the abdomen. The tubes and ovaries were negative, except for a slight degree of edema of the tubes. The anterior wall of the uterus was negative, but the posterior wall was found to be involved in a relatively huge tumor mass extending from the internal cervical os to within a centimeter of the cornua. An attempt was made at myectomy, but the remaining wall was so thin and friable that the more radical supravaginal hysterectomy was performed, leaving the ovaries and tubes *in situ*. Closure was by the usual method. The patient left the table in fair condition.

---

* Compiled by Rebecca Davis Macartney.
Previous excerpts from the Macartney compilation were printed in the July issue (page 61), August issue (page 171), and September issue (page 278).

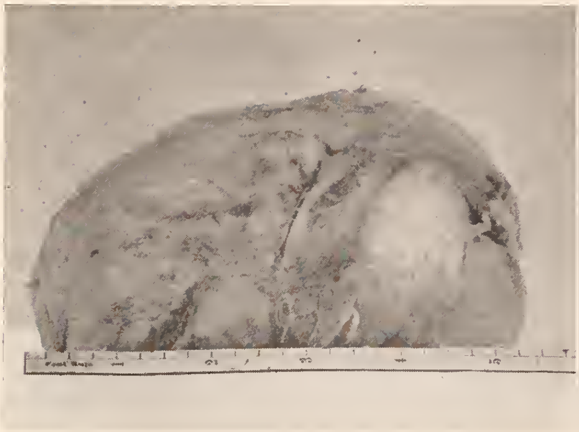

Fig. 1.—Endometrial surface, showing size of tumor.

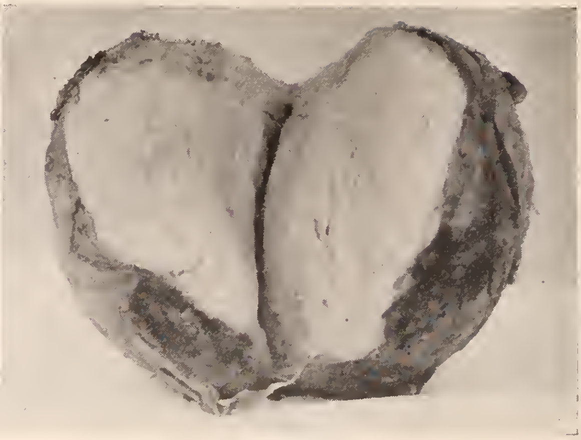

Fig. 2.—Cut section, showing extreme thinness of endometrial covering.

Postoperative course has been uneventful, except for three days of a pyelitic fever, associated with 70 white blood cells to the field in the catheterized specimen. This responded well to therapy, and the patient is now doing exceptionally well.

COMMENT

The accompanying figure amply illustrates the size and type of tumor removed. In consistency it is for the most part a fibroma, with a small amount of muscular tissue. The endometrium over the tumor was thinned out to almost tissue-paper thickness, but otherwise was entirely normal grossly. No microscopic section was done. Postoperative diagnosis: Fibromyoma uteri with hemorrhage; weight, 60 ounces.

1. This is one of those rare cases of fibromyoma uteri occurring in an individual less than twenty years of age.
2. It is also one in which the differential diagnosis between pregnancy and other tumors was difficult, it not impossible, at the time when first seen.
3. This type of tumor can develop with most amazing speed. Check-up of the patient's prior record reveals that not the faintest semblance of a tumor existed in August, 1936.

ACRIFLAVINE AND LIVER DAMAGE WITH A REPORT OF A FATALITY ASSOCIATED WITH ITS USE

By O. C. Marshall, M.D.
Watsonville

Relatively little is known concerning the effect of some of the commonly used urinary antiseptics upon certain organs of the body, especially the liver. It is only in the rare case coming to necropsy wherein urinary antiseptics have been extensively used, and in experimental work upon certain animals, that their action can be studied. The purpose of this report is to summarize the available material in medical literature concerning acriflavine and its effects on the liver with a report of a case terminating fatally, evidently from its use. Further work is being done in the pathology department of Stanford Medical School upon the interesting effects of acriflavine upon the liver.

Acriflavine is one of a class of dyes used as a urinary antiseptic. It is most often prescribed as neutral acriflavine for systemic use and[1] recommended as enteric coated tablets of one-half grain each from three to eight tablets daily (96 to 256 milligrams). Also it is available for intravenous usage in doses of 100 to 500 milligrams, recommended to be dissolved in 20 to 50 cubic centimeters of normal saline and given daily for three days, and then every three to four days. Locally it is used commonly for urethral irrigations.

The action of living tissue indicates it to be a toxic dye. It readily stains the skin, such stain being removed with difficulty, and Heathcote and Urquhart[2] found that heart muscle absorbed and retained it in spite of prolonged perfusion with Ringers' solution. It was found to be depressing to certain tissues, a 1:1,000,000 solution depressing the heart, a 1:25,000 solution depressing intestinal muscle, and a 1:20,000 solution depressing skeletal muscle. Weaker solutions produced some stimulation of intestinal and skeletal musculature. The same investigators reported favorable bactericidal action on staphylococci, but found certain strains of gonococci quite resistant to acriflavine. Gilbrandsen[3] found the minimum fatal dose for monkeys to be about 30 milligrams per kilogram, body weight, and it appeared to kill by depressing the heart.

Heathcote and Urquhart[2] made quite extensive studies upon the action of acriflavine upon dogs, using various-sized doses. They used the drug intravenously and intramuscularly and found: (1) a dose of 50 milligrams per kilo killed at once; (2) sublethal doses of 25 milligrams per kilo at two-day intervals caused death in two to four doses; and (3) repeated smaller doses (5 to 12 milligrams per kilo) by intravenous or intramuscular injections at two-day intervals caused death or produced serious liver damage within fifteen to sixty days.

---

[3] Gilbrandsen: Proc., Roy. Soc. B, 90:136, 1919.

In the case of sudden death by larger doses, the cause was apparently cardiac depression, and in those dying after a delayed period the cause was due to liver injury. Necropsy findings upon those dying within the first week were practically a uniform cloudy swelling of the liver parenchyma and kidney epithelium. Those found from seven to twenty-one days after the first dose of acriflavine showed, in addition to cloudy swelling, an atrophy of the liver parenchyma and kidney epithelium, with some focal necrosis and pigmentation of the spleen. Those dying or destroyed in the interval from the twenty-first to the sixtieth day showed, in addition to the atrophy of the liver and kidney cells, a uniformly common focal necrosis situated chiefly around the central veins of the liver lobules and a congestion of the liver sinuses. The kidney showed a tubular atrophy. The marked pigmentation of the spleen indicated destruction of erythrocytes. The intramuscular sites where injection of the drug was given showed abscess formation.

One feature of the animals surviving sufficiently long was the great degree of emaciation attributed to liver injury.

McKelvey Bell[4] reported its use on persons by intravenous use and by enteroclysis. He considered it effective for many acute infections if used for one or two injections of a one-half per cent neutral acriflavine in 50 cubic centimeters volume at weekly intervals. He often noted alarming symptoms from it and warned against its frequent use.

Murray[5] reported its application in 118 cases, mainly of gonorrhea in the British troops. He used five cubic centimeters of a two per cent solution (100 milligrams) twice weekly, ranging from five to twenty-six doses intravenously. He noted toxic symptoms, and attributed one death to its use as showing an acute yellow atrophy of the liver.

The toxic symptoms are apparently divided into immediate and delayed symptoms. Bell reported complaints of transient fainting, vomiting, palpitation of heart, and two cases of mild shock. Old people complained of several days of weakness, lassitude, and depression following a second dose. Women tolerated the dosage poorly. The people who received four to five injections appeared to develop a gastritis with epigastric pains, nausea, and albuminuria.

Murray noted marked delayed actions appearing after a lapse of eight or more weeks, wherein 11 per cent of all cases receiving acriflavine (doses of five cubic centimeters of a two per cent solution) developed a jaundice against an average of 32 per cent in the untreated British troops. There was apparently no relationship between the number of doses administered and the occurrence of jaundice. Bell also noted a cardiac irritability developing about the fifteenth day. The fatal case reported by Murray presented similar but more marked symptoms than the others suffering from jaundice and, in addition to the icterus, showed loss of appetite and vomiting, slight pyrexia, bile-stained urine, paler stools, and tender liver at the costal margin. In the majority of cases the jaundice disappeared in ten days, and in a majority of cases the men recovered in thirty days. In the patient who died twenty days after hospital admission, diagnosis was acute yellow atrophy of the liver. This patient showed a leukopenia (1,400).

REPORT OF CASE

F. M., Age twenty-four years. American. Bank clerk.

Past History.—Never had had any severe infections; only a mild specific urethral infection in 1927, which responded well to treatment, but which appeared to have become aggravated in October before the use of acriflavine. Past average weight was about 205 pounds (90½ kilos).

Present Illness.—Gave a history of taking six acriflavine tablets daily (192 milligrams) from October 25 to December 22, or a total dose of about 11.1 grams. Early in November he began having periods of malaise, and about the middle of the month developed stabbing epigastric pains, with loss of appetite. Weight loss of 14 to 17 pounds during December, and about the same during the illness in January. During December he became quite weak, and developed marked tenderness in the liver with a constant epigastric distress. About January 6 he became markedly lethargic, associated with insomnia, which persisted until two days before death, when he passed into coma and expired.

Physical Examination.—When first seen on January 8 he was lethargic, and movement of body caused abdominal pain. Jarring over the liver was quite painful. Temperature was normal, pulse 64. On January 9 he developed a jaundice which became increasingly worse until death on January 20. The urine progressively became darker and the stools lighter. Temperature became elevated on January 15 and reached 104.2 finally. Had some vomiting during illness. Abdomen became much distended on the 19th with an anuria. Pulse became increasingly fast and reached 140.

Laboratory Examination.—Urine contained albumin two plus, much bile and, apparently cystine crystals. Widal was negative. Blood count of 6,000 white blood cells.

Clinical Diagnosis.—Acute yellow atrophy of liver.

Autopsy Report.— (Half-hour after death.) Moderate jaundice, with distended tympanitic abdomen present. No edema noted. The abdomen contained about one-half to one quart of dark yellow fluid. The jejunum and duodenum were sprinkled with many hemorrhagic spots the size of pin-heads or larger. The liver was firm in consistency and was decreased about one-third in size. The left lobe and the central portions were more involved than the right. On section the liver showed many regularly distributed nodules or granules on a yellow-green surface. The spleen was moderate-sized and stained a yellow green. The kidneys were moderately enlarged and bile-stained. The heart was enlarged and flabby.

Histologic Examination.—Spleen: Intense congestion of the sinusoids. In places are focal areas of necrosis, in which are rather numerous mononuclear cells, many red cells, and polymorphonuclear leukocytes.

Liver: In large, poorly circumscribed areas corresponding in position to the central parts of the lobules, many liver cells are swollen to several times the normal size, and the cytoplasm of these cells contain many vacuoles, but the nuclei of most cells are intact. Surrounding these cell groups there is a moderate amount of cellular fibrosis tissue, which in places extends between degenerating cells, and also extends into groups of otherwise normal appearing cells. There is a moderate irregular round cell and polymorphonuclear leukocytic infiltration of the fibrous tissue, which also contains large phagocytes filled with brown granular pigment. There are also a moderate number of proliferating bile ducts.

---

[4] Bell, McKelvey: M. J. and Rec., No. 5, Vol. 120, p. 437, 1934.

[5] Murray, D. H.: Acriflavine: Its Use by Intravenous Injection in Treatment of Gonorrhea, J. Roy. Army M. Corps, 54:19-27 (Jan. 30), 1930.

Kidney: Slight congestion and cloudy swelling. The glomerular tufts are normal, though some capsular spaces contain granular material. Many tubules contain small hyaline casts.

Diagnosis.—Cirrhosis of liver, subacute; splenitis, subacute.

COMMENT

This case apparently harmonizes with the clinical effects of acriflavine upon the liver as reported in the literature. Apparently there is an accumulation of the dye in the liver cells which may even produce a progressive injury to the liver parenchyma extending several months after the drug is discontinued. The action appears to be uniform in type, but variable in amount. There must be a large number of cases where injury was present without symptoms severe enough to attract clinical attention. It makes necessary a more critical examination of patients for liver injury, especially those receiving drugs similar to acriflavine in action.

IN CONCLUSION

1. The use of acriflavine systemically and continuously is attendant with dangers.
2. The drug is apparently readily absorbed from the intestinal tract and is retained by the liver cells for a considerable period of time.
3. Acriflavine exerts a decided immediate toxic action on the heart, and a delayed toxic reaction on the liver.
4. It produces a secondary loss of weight due to liver injury.
5. It causes destruction of erythrocytes and a leukopenia.
6. Experimental work is needed on similar drugs as related to liver injury.
7. The fatal case here reported indicates the desirability of enjoining caution on the indiscriminate use of acriflavine.

A SIMPLE ABDOMINAL CUP FOR CONTROLLING CYSTOTOMY DRAINAGE

By Joseph E. Tillotson, M.D.
Woodland

Cystotomy wounds present practical and esthetic features that invariably require much attention on the part of the patient and all who have to do with their care. The writer has improvised a rather simple abdominal cup which eliminates many and minimizes other unfavorable features associated with a cystotomy.

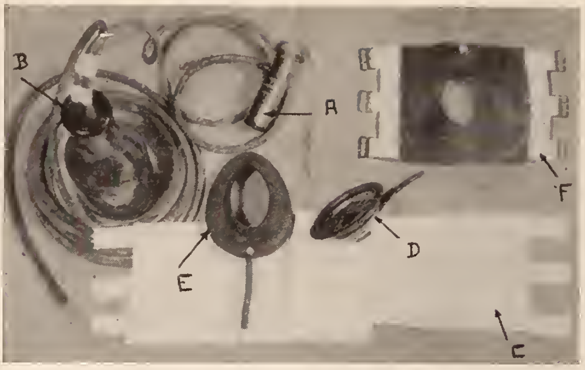

Fig. 1.—Working apparatus, illustrating component parts. A, running-water aspirator; B, bottle with rubber tubing for collecting urine; C, muslin abdominal binder; D, tin cups and copper tubing soldered together; E, pneumatic rubber rim, commonly used on conventional anesthetic inhalers; F, rubber mat, with buckles for attachment to abdominal binder.

The working apparatus, illustrated in Figure 1, comprises the following: A is a running-water aspirator. This is an economic and simple type, attachable to any shaped water faucet. Any suction apparatus, whether running-water type in design or motor-driven, will serve just as well. The bottle, B, is connected by tubing to the aspirator, and further connected by tubing to reach the patient; it collects urine and other discharge from the bladder. The abdominal part of the apparatus is formed of C, D, E, and F. C is an abdominal binder, made of muslin to the exact size of the patient. Two or three are made so that they may be washed and changed daily. D, or the main part of the cup, is made from tin cake-cups fitted with copper tubing and all soldered together. E is a pneumatic rubber rim, commonly used on conventional anesthetic inhalers. F is a rubber mat that goes over the metal cup when the latter is encircled by the pneumatic rim and fitted with buckles for attachment to the muslin abdominal binder. This particular mat was made from a piece of automobile tire inner-tubing and fitted with buckles and straps—a procedure easily done in the sewing department of the usual hospital.

Figure 2 shows the apparatus set up, ready to apply to the patient. Figure 3 shows it fitting on the abdomen. The patient, when his general condition permits, may get in and out of bed with the apparatus attached, working and maintaining complete dryness.

The cup may be applied immediately following a cystotomy operation. Once a day, or oftener, the cup is removed and the gauze changed. In the early stage of a prostate operation, for instance, there may be considerable blood, mucus, and sometimes pus, which may obstruct the cup to a degree, so that occasional cleansing is desirable. After a

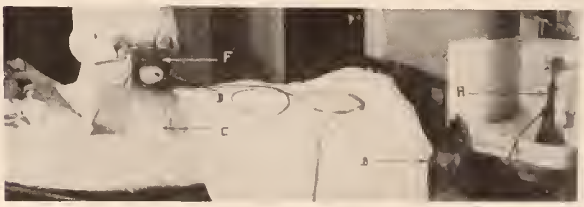

Fig. 2.—Apparatus set up ready to apply to patient. A, running-water aspirator attached to faucet; C, binder encircling body ready to be buckled to F, the rubber mat which steadies the cup, D. In the latter is a small fold of gauze which carries the urine from the surface of the abdomen near the wound to the upper compartment in the cup, where the fluid is aspirated away and collected in the bottle, B.

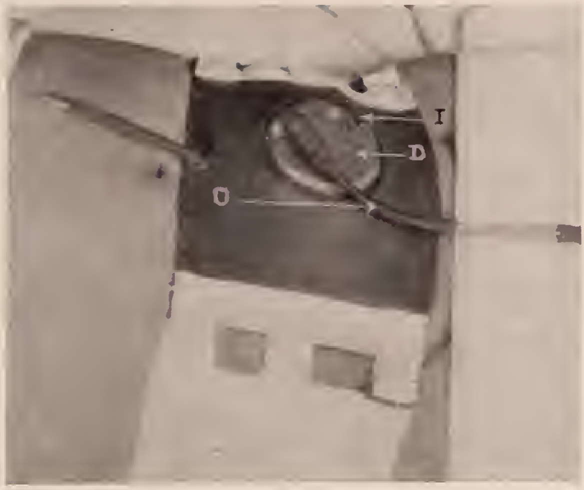

Fig. 3.—Apparatus fitted to abdomen. Air enters copper tubing at I; it leaves through the suction tube, O, carrying along collected urine from the cup, D; and the abdomen remains dry.

few days, however, it is surprising how promptly the urine becomes mucus and odor-free, and the wound also looks healthy and clean. Occasionally at the outset the skin beneath the pneumatic rubber rim becomes chafed and sometimes blistered. Puncture of the blisters and application of tincture of benzoin clear up the condition in a day or two, the skin heals promptly and rarely blisters again.

The suitability of this apparatus is illustrated in the following brief accounts of two of the writer's cases.

REPORT OF CASES

Case 1.—G. G. H., age sixty-seven. Admitted to Santa Monica Hospital on March 8, 1934. Obstructive prostate history of three years' standing; over period of three days before admission, hematuria; on admission, complete urinary retention not decompressible by urethral catheter on account of blood-clots; large prostate rectally; large suprapubic mass, involving also an inguinal hernia; increased blood urea and toxic. Repair of hernia separating bladder therefrom and cystotomy were performed; the bladder was full of old blood-clots, pus, and urine. A large caliber cystotomy tube was inserted and the cystotomy cup applied. Three days later the bladder discharge was free of blood, and toxicity of patient had subsided. Ten days after cystotomy the prostate was removed and the cystotomy cup applied. The patient returned home ten days later; there was still some cystotomy drainage, and use of the cystotomy cup was continued at home.

Twelve years before the present operation the patient had had a suprapubic cystotomy and prostate operation by a reputable surgeon. At this time syphon drainage was employed. The patient thus had an opportunity of experiencing two types of after-care for practically the same condition. He was ever enthusiastic in emphasizing the dryness and greater comfort in the use of the abdominal cup. To insure prompt and effective decompression, and as a safeguard against further accumulation of blood-clots in this case, a cystotomy tube of large caliber was used; this was easily adaptable to the cystotomy cup. Three days following the prostatectomy, when all tubes were out of the bladder, the cystotomy cup was still employed, maintaining complete dryness.

* * *

Case 2.—E. M., age sixty-four. Admitted to Sutter Hospital, Sacramento, June 16, 1935. Obstructive prostatic history of several years' standing; recent hematuria; on admission to the hospital, complete urinary retention not decompressible by urethral catheter due to blood-clots. Large prostate rectally, increased blood urea, and toxic. A cystotomy was done, at which time the bladder was found filled and distended with old and new blood-clots. Large cystotomy tube was inserted and the cystotomy cup applied. Within four days urine was blood-free and toxicity had subsided. Twelve days after cystotomy, prostate was removed. Cystotomy cup was applied right afterward, and two days later was still effective, when all tubes were removed from the bladder.

In this case, as in the former one, the cup was adaptable where a large cystotomy tube was desirable for prompt decompression and for a safeguard against reaccumulation of blood-clots in the bladder. It was also practicable to use effectively for dryness and cleanliness after all tubes were removed from the bladder, and later when the margins of the cystotomy wound were brought together.

SUMMARY

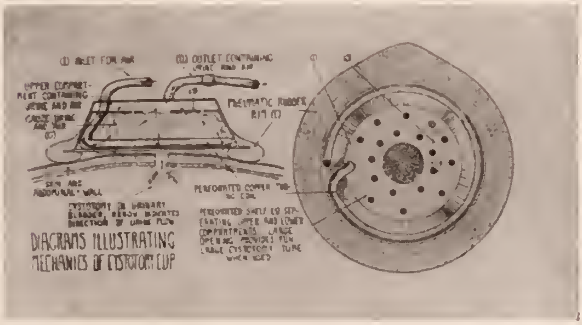
A simple abdominal cup for controlling cystotomy drainage has been illustrated. There are several advantages in the use of the cup:

1. The patient is kept dry—the usual discomfort of continuous large wet dressings is eliminated. The nervous strain and potential complications of large wet dressings are reduced.

2. The cup can be employed where no drain of any kind is in the bladder, or it may be employed where a cystotomy tube of large caliber is desirable for removing large blood-clots or other obstructive material.

3. It insures continuous gentle decompression with removal of urine and exudate, and this continuous action promotes cleanliness of the bladder and wound and protection against infection.

4. Toilsome and unpleasant nursing care is minimized. There is large economy in dressings.



(I) INLET FOR AIR
(O) OUTLET CONTAINING URINE AND AIR

Fig. 4.—Diagram illustrating the mechanics of the metal cup.

In short, the principle involved is that of a current of air blowing continuously over the surface of the wound and carrying off the bladder discharge. The aspirator creates the current of air. When the latter operates, air flows in through the inlet, I; encircles through the copper coil; passing through the perforations in the coil, the air blows through the lightly packed gauze, G, which becomes saturated with the bladder discharge, and causes a flow of the urine, blood, etc., above the shelf, S, into the upper compartment in the cup, from which space the discharge is carried away through the outlet, O, to the collecting bottle. When the pneumatic rim, E, is inflated and wet, it adheres water-tightly to the skin of the abdomen, and there is required only slightly diminished interior pressure to maintain this fixation and this is without undue suction on the skin or bladder. There is no marked vacuum pressure here, for air is rushing in continuously through the inlet, I. The binder with the rubber mat merely acts as a steadying influence, and not as a major factor, maintaining the water-proof adherence of the pneumatic rim to the skin. One need not fear pressure necrosis to the bladder mucosa due to the latter pressing against an indwelling bladder tube, because the suction pressure is minimal. Moreover, a cystotomy tube may be removed, depending on individual circumstances, and the bladder discharge will be carried away effectively from the abdominal surface of the wound.

BEDSIDE MEDICINE FOR BEDSIDE DOCTORS

CANCER OF THE FUNDUS UTERI

ETIOLOGY AND PATHOLOGY

Paul E. Hoffmann, M. D. (Stanford University School of Medicine, Department of Obstetrics and Gynecology, San Francisco).—Uterine cancer is found most often in women in the fifth decade, but may occur from the second to the eighth. An important etiologic factor is its association with fibromyoma. Stacy found 33.45 per cent of corpus cancer associated with fibromyoma in a series of 269 operated cases. In our clinic service we have seen eighty-four cancers of the fundus, and ten of these were associated with fibromyomas.

It is difficult to say just what the etiologic relationship between fibromyoma and cancer is. The interference of the fibromyoma with uterine drainage, and irritation from trauma by a submucous tumor have been considered etiologic factors. Some workers believe that there is a relation between carcinoma and adenomyoma of the uterus. Malignancy in the presence of hyperplasia of the endometrium is rarely seen. Tuberculosis has been observed in uterine carcinoma.

Benign overgrowths occur in the surface of the uterine mucosa as the result of chronic pyometra and following curettage when escharotics or styptics have been used. The regeneration of the surface epithelium may result in a proliferation of the epithelial cells, with partial or complete epidermization. Differentiation between this overgrowth and an early malignancy is very difficult. This epidermization, or leukoplakia, should always be regarded with suspicion and considered as a precancerous condition. In spite of extensive investigations, no one has yet definitely proved that chronic hypertrophy, hyperplastic changes, polyp formation, or chronic inflammatory conditions are responsible for the occurrence of cancer of the corpus uteri.

Pathology.—The anatomical forms may be divided into (1) diffuse and (2) circumscribed growths. The first may be an advanced stage of the second, but it is probable that certain diffuse tumors arise over a wide area. The earliest stages of the localized neoplasms appear as low thickenings in the endometrium, but definite outgrowth into the uterine cavity occurs early and forms polypoid or papillary projections. Certain tumors always remain distinctly papillary.

Bulky growths, which destroy the uterine cavity and invade the myometrium, are produced in the advanced stages. The cervical canal is rarely involved in corpus carcinoma, but groups of malignant cells may undermine the cervical mucosa. Because of the growth in the uterine cavity, a general enlargement of the uterus results. However, in some instances fibromyomas associated with the neoplasm account for the increased size. If the myometrium is intact, the prognosis is more favorable, and in some instances cures have followed simple curettage. If the growth is not arrested, it will eventually perforate the uterine wall and invade the bladder, rectum, or peritoneal cavity. The advanced stages of this malignancy are marked by excessive polypoid formation, ulceration, necrosis, and deposition of calcium.

Formerly all corpus cancers were considered as a single pathologic entity of the adenocarcinoma variety, but in the light of more recent studies the tumors have been classified into five histologic grades, or groups:

1. A superficial papillary adenoma, which runs a slow and rather benign course. Infiltration is absent. The cells are not very atypical.

2. Malignant adenoma, histologically a more malignant lesion characterized by greatly elongated alveoli, which are lined by several layers of cuboidal and cylindrical cells. The alveoli occur in groups separated by strands of stroma. The cell nuclei characteristically stain very deeply, but the cytoplasm is pale. Mitotic figures are common.

3. Adenocarcinoma, which differs from the above tumors in that invasion of the uterine wall occurs early. The neoplasm presents a glandular or papillary structure, but may be almost solid. The cells form multiple layers or solid columns, and the polarity of the cells is disturbed. In the solid portion the cells are even more atypical with marked variations in size, shape, and staining reactions. Invasion of the muscle and lymphatics occurs quite soon, and the tumor runs a malignant course. This type may occur in uterine polyps.

4. Grade 4 is a solid cellular adenocarcinoma. These tumors lose all semblance to any glandular arrangement, and replace myometrial tissue to the point of rupture. The cells are small, round or polyhedral, and stain deeply. Mitoses are numerous and there is complete loss of differentiation in the cells. Giant cells occur and occasionally the structure resembles lymphosarcoma.

5. True adeno-acanthoma, with squamous epithelium and pearl formation, is occasionally seen. In this type of neoplasm, squamous cells are the predominating tissue, and the tumor probably develops at the site of a leukoplakia. The squamous cells appear in foci in the alveolar lining, and may show evidence of hyaline degeneration.

A characteristic form of uterine carcinoma which is very malignant may originate in a diffuse adenomyomatosis. These tumors may occur deep in the uterine wall and extend to the adjacent tissues quite early. Various forms of adenocarcinoma, solid or alveolar types, are observed in these tumors.

SYMPTOMS AND DIAGNOSIS

Lawrence F. Eder, M. D. (1421 State Street, Santa Barbara).—The tendency to regard carcinoma of the fundus as a relatively benign and easily cured disease has done much to increase the number of deaths due to this malignant growth. The chance of cure of carcinoma of the fundus is similar to that of carcinoma of any other organ: the earlier it is discovered and treatment instituted, the higher the percentage of cures. And, as in other carcinomas, an early diagnosis is too rarely made. This is in part due to the fact that carcinoma of the fundus most frequently occurs at a time when menopausal disorders are present. The menstrual irregularities which are so common at that age frequently mask the presence of an early carcinoma of the fundus. The early warnings are tolerated by the patient in the belief that such manifestations are normal and to be expected of the menopause.

The difficulty of diagnosis is, likewise, increased by the presence of myomata of the uterus. Large series of cases of fundal carcinoma show that over 25 per cent are found in association with myomata, the presence of which alone would account for the symptoms.

The most common early symptom is abnormal vaginal bleeding. This occurs, in 100 per cent of the cases, some time during the progress of its growth. The bleeding is usually intermenstrual in type, beginning as a slight spotting, which becomes more marked in amount and more frequent as the area involved increases. Profuse bleeding rarely occurs until the later stages. If the malignancy begins during the menstrual life, the periods may be a little more profuse or prolonged, or there may be a slight spotting just before the onset of the expected flow. However, this confusing coincidence is not the rule, as carcinoma of the fundus occurs most frequently after the cessation of menstruation.

Occasionally the first symptom noticed is a thin, watery vaginal discharge. It is usually irritating, and may or may not be blood-streaked. If there is degeneration of the surface of the tumor, the discharge will be malodorous and may contain sloughing particles. This discharge may be ignored by the patient until it becomes more sanguinous in character.

Pain is rarely present until the later stages of the disease. There may be a slight sacral backache, or a feeling of pelvic discomfort which the patient is unable to describe in definite terms. After considerable growth of the tumor with metastases or parametrial involvement, there may be considerable lower abdominal and pelvic discomfort. However, during the early stages pain is not present and is of no diagnostic aid.

The personal history of the patient is rarely of diagnostic significance. The most common age of onset is during the fifth decade. Hereditary history of cancer is present in approximately 10 per cent of the cases. The parity of the patient is not of great importance, for over 25 per cent occur in nulliparous women. The duration of symptoms is misleading, for it varies from six months to two years, and depends on the type and grade of the malignancy.

Physical examination of the patient rarely reveals general signs, such as cachexia, loss of weight, and palpable masses, until the growth is advanced.

Pelvic examination: In the early period of growth of the tumor the uterus is usually normal in all characteristics. There will be no change in the size nor consistency of the uterus until the carcinoma has progressed for a time sufficient to cause a uniform enlargement and a barely appreciable softening or bogginess. Metastases occur relatively late, and palpable parametrial masses are found only in the advanced stages. Metastases to the regional lymph glands are rare.

As a diagnostic office procedure, the Clark test may occasionally be advantageously employed. The vagina and cervix are exposed with a speculum and cleansed with a mild antiseptic solution. An ordinary uterine sound is inserted into the uterine cavity and gently manipulated so as to contact the entire endometrial surface. If a friable, vascular carcinomatous area is contacted, there will be a small amount of bleeding around the sound or from the cervix after the sound is withdrawn. Care must be used not to perforate through a soft spongy area.

Ewing has been able to take fundal smears and to identify the cancer cells in this manner.

Blood serum reactions, such as Roffo's test, may be positive in the later stages of the disease, but have no great diagnostic certainty.

The symptoms of early carcinoma of the fundus, therefore, are not sufficiently alarming to the patient to demand medical opinion. The absence of local pain and frank hemorrhage belie the seriousness of the condition. Nor are the physical findings of sufficient distinction to merit a clear-cut diagnosis of early fundal cancer. However, the history of abnormal vaginal bleeding or discharge, especially within certain age limits, which cannot be explained on obvious grounds, should always be considered as strongly suspicious of carcinoma of the fundus.

These suspicions can be changed to an actual diagnosis only by a microscopic examination of the tissue. Therefore a diagnostic curettage must be done in all suspected cases. The curettage must be thorough in order that a small area of malignancy will not be overlooked. Care must also be used in selecting the tissue which is to be examined. Curettage is undoubtedly a much abused procedure, but it is the only one by which a definite diagnosis can be made. For this reason a thorough curettage should be done before intrauterine radium is inserted for the treatment of myomata of the uterus in order that a coexisting carcinoma will not be overlooked.

The symptoms and physical findings of the more advanced stages greatly simplify the diagnosis. Diagnostic curettage should be done in these cases to determine the type and grade of malignancy.

PROGNOSIS AND TREATMENT*

Verne C. Hunt, M. D. (727 West Seventh Street, Los Angeles).—*Prognosis.* In general it may be stated that the prognosis of carcinoma of the uterine fundus is the most favorable of any of the malignant lesions except those of the skin. While there are many factors upon which the prognosis of cancer in general is dependent, most of them are particularly favorable in carcinoma of the uterine fundus. This is particularly true when such lesions are contrasted with primary malignant disease of the uterine cervix which occurs more than twice as frequently as carcinoma of the uterine fundus. While carcinoma of the uterine cervix, often far advanced before alarming symptoms occur, is an invasive lesion, tends to progress rapidly, often metastasizes early, and is usually of high-grade malignancy, the reverse in all particulars is usually true of carcinoma of the uterine fundus. Carcinoma in the latter situation usually, or often at least, is a localized lesion productive of menstrual irregularity or intermenstrual spotting of sufficient degree during the menstrual age, or productive of postmenopause bleeding sufficiently early in its course to lead to diagnostic curettage and microscopic examination of uterine scrapings. Inasmuch as carcinoma of the uterine fundus is not particularly invasive, progresses slowly, and does not tend to metastasize early, the diagnosis is most frequently made while the lesion is a localized one, as contrasted with the state of affairs in most instances when the diagnosis of malignant disease of the uterine cervix is made. Likewise, the degree of malignancy of carcinoma of the uterine fundus is low in a high percentage of cases, while the degree of malignancy in carcinoma of the uterine cervix usually is high. Some years ago, in a series of 455 cases of carcinoma of the uterus that I reviewed (which consisted of 186 cases of carcinoma of the uterine fundus and 269 cases of carcinoma of the uterine cervix), in which the lesions were graded according to their degree of malignancy, it was shown that 66 per cent of the cases of carcinoma of the fundus were of low-grade malignancy (Grades 1 and 2), and 33 per cent of the cases were of high-grade malignancy (Grades 3 and 4). Only 8.5 per cent of the cases of carcinoma of the uterine cervix were of low-grade malignancy Grades 1 and 2), while 91 per cent of the cases were of high-grade malignancy (Grades 3 and 4). In other words, from the standpoint only of the degree of malignancy based on cell differentiation, the prognosis should be much better in carcinoma of the fundus than in carcinoma of the uterine cervix. This is borne out in a report which I have previously published in which it was shown that only 18 per cent of the patients with carcinoma of the cervix who had been operated upon were living five years after operation, as compared with 64 per cent of the cases of carcinoma of the uterine fundus who were living five years after operation. Of the various factors that are concerned in the curability of carcinoma of the uterus, the degree of malignancy based on cellular differentiation is the most important. On account of the tendency for carcinoma of the uterine fundus to remain as a localized lesion, the operability of the disease in this situation is high and the prognosis is favorable, on the basis that the majority of cases show a high-degree of cellular differentiation and the more highly malignant lesions are in the minority.

Treatment.—While there are many factors concerned in menstrual irregularity, menorrhagia, intermenstrual spotting and other manifestations not entirely regular and in order, they should not be too readily explained on the basis of ovarian dysfunction or menopausal disturbances. A normal size uterus and the absence of a lesion of the cervix does not allow one to hastily infer that disease within the uterine fundus does not exist. It is, likewise, noteworthy that, because fibroids are readily palpable, one may not hastily assume that associated intra-uterine malignant disease does not exist, and that the apparently innocent fibroids provide sufficient cause for menstrual irregularity or postmenopause bleeding. I have previously stated elsewhere that fibromyomas of the uterus were associated in 30 per cent of the cases of carcinoma of the uterine fundus. Certainly, when any question of doubt exists it is imperative that one urge a diagnostic curettement and careful microscopic examination of the uterine scrapings.

Operability of carcinoma of the uterine fundus requires that the lesion is confined to the fundus, without invasion of the cervix or the broad ligaments, without fixation of the uterus, and the absence of demonstrable regional or remote metastases. In the truly operable cáses in the absence of associated disease, by virtue of which the excessive surgical risk precludes operation or by virtue of which the expected longevity is not great, total hysterectomy with removal of both tubes and ovaries provides excellent prospects of cure of the disease. Except in instances of considerable abdominal obesity or marked uterine prolapsus, under which circumstances vaginal hysterectomy may be readily accomplished, the operation of total abdominal hysterectomy is usually most advantageously employed within a mortality rate of 5 per cent. The question of infection associated with carcinoma of the uterus has caused the operation of total abdominal hysterectomy to be accompanied in the hands of many surgeons by a somewhat higher mortality rate than the same surgical procedure for benign disease of the uterus. It has frequently been observed, particularly in those cases in which carcinoma of the uterine fundus has developed in the postmenopause period, that a considerable pyometria coexists. A preliminary procedure of vaginal suture closure of the cervix in all cases of carcinoma of the fundus prevents contamination of the operative field through the escape of such infective material during the course of the surgical procedure of hysterectomy. Furthermore, the use of the cutting cautery in making the dissection down around the cervix and across the vaginal vault, in all cases of total abdominal hysterectomy for benign or malignant disease of the uterus, has served a most excellent purpose in minimizing, if not entirely eliminating, contamination from within and about the cervix.

---

* Submitted September 20, 1935.

Some question justifiably exists whether or not both the ovaries should be removed in all cases coincident with total hysterectomy. In patients with early malignant disease some ovarian tissue may at times be preserved for one reason or another; however, as a general principle, the complete removal of both tubes and ovaries simultaneously with total hysterectomy assures the best prospects of cure. Offutt showed quite conclusively that some relationship exists between carcinoma of the body of the uterus and carcinoma of the ovaries. In 520 cases of adenocarcinoma of the body of the uterus there was associated carcinoma of the ovaries in 11.9 per cent. Unquestionably, the fallopian tubes provide a direct route for extension of malignant disease from within the uterus to the ovary. In fact, Offutt found carcinomatous cells in the lumen of the fallopian tube in several cases of carcinoma of the body of the uterus. Likewise, Sampson has presented convincing evidence that migration of cells takes place through the fallopian tubes from the uterus, and he demonstrated endometrial and carcinomatous cells in the ovary and peritoneal cavity that had originated in the uterus. Furthermore, when one or the other ovary is involved in malignant disease of the uterine fundus, bilaterality of ovarian involvement occurs sufficiently often that seldom may one be justified in preserving ovarian tissue when performing total hysterectomy for carcinoma of the uterine fundus.

The operation for carcinoma of the uterus that was introduced by the Viennese surgeon, Wertheim, and which bears his name, is one which is seldom justifiably instituted for carcinoma of the fundus of the uterus. The operation consists not only of total abdominal hysterectomy with the removal of both tubes and ovaries, but also wide excision of all pelvic gland-bearing structures, including those along the iliac vessels. Its need and usefulness at about the time of its introduction, particularly for carcinoma of the uterine cervix, was far greater than at the present day; for at that time the effectiveness of the physical agents was not great. The mortality rate of 15 to 20 per cent attending this extensive surgical procedure has hardly justified continued usefulness of the operation, for it is extremely doubtful that the percentage curability of cancer of the uterus has been increased, when the excessive mortality of the operation is taken into consideration.

The extensive usefulness of the physical agents in the treatment of carcinoma of the uterine cervix which has advanced beyond operability quite naturally presents the question of the status of radiotherapy in the treatment of carcinoma of the uterine fundus. From the preceding statements regarding prognosis it is quite apparent that carcinoma of the cervix, and carcinoma of the uterine fundus, differ materially one from the other, not only in their degree of malignancy, their progression and extension, but also in their accessibility. The operability of carcinoma of the uterine fundus is high, while the reverse is true of malignant disease of the cervix. Little, if any, controversy exists today regarding the merit of total hysterectomy for truly operable carcinoma of the body of the uterus in the absence of general contraindications, and there is little, if any, suggestion from any quarter that radiotherapy is a justifiable substitute for such surgical procedure. There is little to suggest anticipated improvement in the results of total hysterectomy through preoperative radiation of operable carcinoma of the body of the uterus. There, likewise, is little evidence to support the suggestion of postoperative radiation in those cases of carcinoma of the uterine fundus in which at operation the disease is found to be an entirely localized, non-invasive type of lesion. However, postoperative radiotherapy may justly receive favorable consideration as an adjunct to total hysterectomy, if at the time of operation the lesion has been proved to be one of high-grade malignancy, or is invasive, or in which there is irremovable regional glandular involvement. Also radiation may be decided upon as the sole method to be used in the presence of distinct contraindications to a surgical procedure by virtue of associated disease providing an unjustifiable surgical risk or a short life expectancy. Likewise, radiation has proved of considerable merit in the cases of inoperable carcinoma of the uterine fundus, seldom in the production of cure in advanced cases, but often productive of much palliation.

Doctor, Please Return Your Questionnaire.—The Scientific Research Division of the United States Public Health Service has been conducting a health survey in certain localities in California. These localities are: San Francisco Bay area, Vallejo, Napa, Chico, Jackson, Grass Valley, Bakersfield, and certain sections of Los Angeles.

The purpose of the survey is to ascertain the rate of illness sustained by individuals and the diagnoses given by the doctor as well as the number of days of illness of a given period.

Some 40,000 questionnaires were sent out with a frank return envelope. Of this number, some 30,000 have been returned. The doctors returning the questionnaire are given 25 cents for each report.

The Public Health Service is desirous of obtaining a 100 per cent return, because only by such return can full value of medical data be determined.

You are, therefore, urged to return whatever questionnaires have been sent you.

Insurance on Health Studied.—The San Francisco *Daily News* of September 9 printed the following item:

"All credit unions of San Francisco and the East Bay will consider a medical and hospital insurance plan for 40,000 California credit union members next Monday night at the Women's City Club, 1428 Alice Street, Oakland, it was announced today by Leo H. Shapiro, chairman of directors.

"Northern California committees studying a medical program to assure employees full medical and hospital services for the payment of a small monthly fee also will attend the conference. The plan would embrace 7,500 San Franciscans.

"Participating in the meeting will be State Senator Dan Williams of Sonora, chairman of the Legislative Committee on Health Insurance, and Dr. Philip King Brown, leader of the movement."

CALIFORNIA MEDICAL ASSOCIATION

This department contains official notices, reports of county society proceedings and other information having to do with the State Association and its component county societies. The copy for the department is submitted by the State Association Secretary, to whom communications for this department should be sent. Rosters of State Association officers and committees and of component county societies and affiliated organizations, are printed in the front advertising section on pages 2, 4 and 6. Articles listed under the caption, "This Month's Topics," have been contributed by the Association's Secretary.

ASSOCIATION ACTIVITIES

HAVE YOU A PAPER?

Last month, under the above caption, an invitation was extended to members to send in their names and subjects if they were willing to present a paper or demonstration before our county societies. The statement was made that frequently the headquarters office is appealed to for speakers for county society programs. A list of members is being compiled and will be kept for reference so that a selection can be sent to county secretaries and enable them to arrange scientific programs.

The response was not gratifying—only eight answers were received. Therefore, this request is being republished. If you are willing and will respond to an invitation from a neighboring county society to present a paper or clinical demonstration, will you please send in subject, brief synopsis, and length of your paper, together with your name, address, and telephone number?

County meetings are being resumed. Will *you* help in making these programs interesting, practical, and inducive to large attendance? You can by responding to this request. Won't you write today? Thanks a lot.

* * *

AUTOMOBILE DRIVERS' LICENSE

During the month a four-hour conference was had with the department head of the Drivers' License Bureau of the State Traffic Division. The state official came in with his problems related to the physical and medical aspects involved in denying or revoking automobile drivers' license.

Several files were presented that included traffic and police reports, court records, and medical certificates of physical fitness. The wonder was that licensed physicians would append their names to such certifications that lay enforcement officers knew were not substantiated by present medical knowledge.

By way of illustration the following are examples of signed certificates, by members, in an endeavor to establish that the party involved was a safe driver and should have a license or should not have his license revoked:

(*a*) Epileptic, taking ten grains of sodium luminal a day.

(*b*) Diabetic, taking 80 units of insulin per day (had two accidents while in insulin shock).

(*c*) Diabetic, requiring 7,200 insulin units per month.

(*d*) Insomnia (?) taking ten grains of nembutal daily and a known alcoholic.

(*e*) Reported normal vision with correction, yet on recheck had 20-60 and 20-100's.

(*f*) Total color blind, certified as having normal vision, yet has record of running four red lights in two weeks.

(*g*) Epileptic; three accidents during seizure. Was certified as having no physical defects.

The department's problem, in an earnest endeavor to reduce the present high automobile death rate and to protect drivers on the highway from these incompetent operators of trucks and passenger cars, is a grave one. An earnest effort is being made to reduce the death toll on our streets and highways. Individual and legal rights are involved. Unwarranted medical certification must be eliminated. There can, there must be no evasion or condonement when medical certificates are signed.

Arrangements are now being perfected whereby shortly a secret medical board of nine referees will be appointed that will review and make recommendations when traffic records and accidents indicate that a medical certification does not warrant the statements contained in the original medical certificate. If you give false certificates you become a party to any ensuing accident, or even death, due to physical defects in the driver involved. The medical profession must do its part in reducing automobile accidents.

* * *

SERVICES AVAILABLE TO YOU AT ASSOCIATION HEADQUARTERS

The following services are available to members and are obtainable by application to the Association's offices:

1. Mailing-list of members and addressing envelopes. (A small charge is made to reimburse addressograph operator.)
2. Literature on medico-economics.
3. Bibliographies.
4. Reference library.
5. Answers to inquiries on medical, economic, health, and legislative subjects.
6. Ratings of schools and hospitals.
7. Time and place of state and national meetings.
8. License and registration requirements.
9. Medico-legal decisions.
10. Consulting specialists.
11. Approved sanitariums.
12. Postgraduate schools and courses.
13. New and nonofficial remedies.
14. Radio broadcasts (medical).
15. Governmental agencies and service.
16. Approved laboratories.
17. Collection agencies.
18. Locum tenens (not always).
19. Practice openings (not always).
20. Approved investment agencies.
21. Ethics and professional conduct.
22. State and national medical policies.
23. Training in medical specialties.
24. Medical libraries.
25. General professional information.

These are but some of the services obtainable by reason of your membership affiliation. Your inquiries are welcomed and will receive prompt replies.

MEMBERSHIP RESOURCES AND ASSETS

1. Advantages of regular scientific meetings and discussions, district meetings, annual state session, clinics, and social functions.
2. Individual betterment contributing to betterment of entire profession.
3. Affiliation with an organized unit which with other units form the state unit whose Council, officers, and committees are charged with the responsibility of promoting professional interests as well as being on guard to expose and defeat movements and issues that are subversive to the public's and the profession's welfare.
4. Central information bureau.
5. Official publication, California and Western Medicine.
6. Eligible for American Medical Association Fellowship.
7. Protection for your professional work.
8. Postgraduate opportunities.
9. Endorsement of individual standing by peers.
10. Association with fellow physicians.

* * *

THREATENING LETTERS

Sooner or later a physician in active practice will receive a threatening letter from a disgruntled patient or one who is seeking to evade payment for services received. The letter may be written by the patient or by an attorney who has solicited or been retained by his client. Veiled threats are made and a reply or a call is requested "to avoid resort to legal proceedings."

The recipient physician is quite liable to "blow up" and in the heat of anger commit his reactions in a letter or in an explosive interview with the complaining parties—all to his future detriment. Should the issue come to trial, the "answering letter" or a repetition of the heated interview will find its way in the testimony for jury consideration.

This advice is given: *Never answer or respond to any threatening letter.* Refer it to your insurance attorney, who knows better than you do how to answer the threat and protect your interests. It may be difficult to resist "blowing off," but discretion is better than the passing satisfaction obtained from "That's telling him," which may backfire to your damage when the day in court arrives.

Clamp down on the safety valve; refrain from writing or explaining; do not enter into a discussion or make comment. Consult your attorney and allow him to handle the entire matter for you. Resolve, never to answer or reply to a threatening letter; your attorney knows best how to handle the situation. Depend on him and you will have peace of mind.

* * *

CONSTITUTION AND BY-LAWS

In the August issue the Association's Constitution and By-Laws were reprinted. The several amendments adopted at recent annual sessions are incorporated in this reprinting. A sufficient number of special copies of our Constitution and By-Laws have been acquired, and a copy has been sent to each county society secretary for reference and preservation in county files.

Members are urged to preserve the August issue for their personal reference.

A Few Peeves, or Things We Can Do Without

1. Uninformed legislators.
2. Detail men for "not Council approved" medicinal preparations—ditto for electrotherapy equipment.
3. Citizens (?) who neglect to register and vote.
4. The unwilling-to-be-advised politician.
5. Trade journals that lift their reading matter from recognized medical publications profiteering on advertising income from questionable advertising.
6. Two-thirds of the advertising junk contained in each mail delivery.
7. Music during dinners and banquets which are arranged primarily for renewing acquaintanceship.
8. Middle of the road drivers and corner cutters.
9. Punch boards to raise funds.
10. Laymen who think they alone are competent to direct and provide medical services.

C. M. A. DEPARTMENT OF PUBLIC RELATIONS†

"E" Men

President Sensenich of the Indiana State Medical Association recently wrote: "The medical profession without its journals, like a nation without a public press, would be uninformed, incoördinated, and helplessly inarticulate."

"The E-Men of Medicine, the editorial personnel of medical publications, are the directors of this transmission system." He then pays deserved tribute to the "E" men of Indiana.

We would go further and pay tribute that is deserved to all the "E-Men of Medicine" in this country. Because of their service, vision, fearlessness, and leadership, we would like to nominate for the "E-Men in Medicine" hall of fame: Bulson of Indiana, Taylor of Texas, Whalen of Illinois, Hammond and Donaldson of Pennsylvania, Meyerding of Minnesota, Shanklin of Indiana, and last, but not least, Phil Jones, Musgrave, and Kress of California. There are other "E" men, but their nominations are left for others. The names mentioned represent editors who for many years have crystallized opinions and policies that have clarified medicine's problems and ennobled the temple of medicine and the medical profession. They have been most influential in guiding the profession and creating safe, just and constructive movements. Every organizational member is indebted to the "E" men in medicine. That indebtedness should be acknowledged frequently and earnestly.

* * *

Economic Budgets

Comfort, luxury, pleasure, are human quests and weaknesses. Food, clothing, fuel, and shelter are basic needs. A fifth basic need, physical welfare and medical care, is passed into the discard by luxury expenditures. It is not until the emergency arrives and medical care becomes a necessity that most individuals realize that they have failed to make provision for it in their budget. Confronted with the need for medical care and having failed to provide for it, the individual calls upon the physician or society to assume the burden of his neglect and provide him with that which he should have prepared for ere expending reserves for luxuries. A human trait that has been condoned and, in great measure, abetted by governmental agencies.

That trait will continue and will grow unless economists, governmental agencies, and society initiate a movement to educate and impress the individual that the provision for medical care is his personal responsibility and obligation. Appropriation of funds for these educational movements will be a lesser drain upon the taxpayer and the community than would be the tremendous amount required to provide medical care by means of tax-raised funds.

American citizens need to be enlightened as to their personal responsibilities. You say, "Try and do it" and "utterly impossible in these times of governmental paternalism and spoils"—a defeatist attitude. Had such a position been assumed in the years past, we would still have the plagues of smallpox, diphtheria, typhoid, and tuberculosis, because when public education to eradicate these diseases was undertaken the task to do so seemed as hopeless and impossible as is the task of endeavoring today to commence to cause individuals to recognize that medical care is a basic need that should be met by the individual. We prefer to try and fail than not to start trying.

---

† The complete roster of the Committee on Public Relations is printed on page 2 of the front advertising section of each issue. Dr. Charles A. Dukes of Oakland is the chairman, and Dr. F. C. Warnshuis is the secretary. Component county societies and California Medical Association members are invited to present their problems to the committee. All communications should be sent to the director of the department, Dr. F. C. Warnshuis, Room 2004, Four Fifty Sutter Street, San Francisco.

As to the need of trying, cogitate on these figures, imparting the luxury expenditures of the average family per year:

Automobile	$150.00
Tobacco	67.00
Gasoline	37.00
Candy	37.00
Movies and entertainment	35.00
Sodas, ice cream, and gum	34.00
Jewelry and furs	29.00
Liquor	25.00
Radios	16.00
Cosmetics	15.00

The average medical bill for the family, if it is paid, is $62 per year, but more is spent for tobacco. Twice as much is spent for candy than for hospitals. Twice as much is spent for cosmetics as for nursing. Luxuries exceed necessities and basic family needs.

Certain states and communities are balancing their budgets and reducing taxes. A light is dawning, and persons with annual incomes of $1,400 in this state, paying $1 per day in taxes, are beginning to demand a halt. Politicians and lawmakers will listen to that demand if we make it loud enough.

* * *

Elevators Spread Contagion

We have often wondered why health departments and officials have not devised a terse, arresting slogan to be placed in public elevators, to prevent spread of infection by coughing and sneezing.

Most everyone has some time or another ridden in an elevator and has been deluged with the spray of a sneeze or cough by a copassenger. Personally we have been tempted to speak our piece to the offending passenger and berate him or her for their infection-disseminating act. Signs are placed in other public conveyances. Elevators, especially in these days of tall buildings, carry thousands of passengers hourly, all confined within a small space. The cougher and sneezer always hits the bulls-eye with his spray.

An ordinance is suggested compelling building owners to place a neat attention-arresting warning sign in all public elevators. Someone can probably suggest a better warning than these: "If you must cough or sneeze, cover your face." "Prevent the spread of contagion by covering your face when you cough or sneeze." "Do not transmit your infection to fellow passengers by unprotected coughs and sneezes."

It is hoped that health officers will adopt this suggestion, which may aid in reducing nasal respiratory infections. Make elevators sanitary public conveyances.

* * *

Lay Health Meetings

A major activity of county medical societies is the education of the public upon the questions of private and public health. It is a fact that a lay person consults a cultist mainly because of lack of information and inability to discern the difference between scientific medicine and the pseudoscientific representations of cults. The average person, once informed, will discontinue consultation with a member of a cult. The many uninformed persons accounts for the fact that only about 50 per cent of the medical care required by the public is rendered by licensed physicians and surgeons. Hence education of the public is a major responsibility of our constituent units.

This educational program is not inspired by mercenary reasons. It is based on the centuries of service through which medicine has always exhibited its concern for the advancement of the health welfare of the public. Edgar A. Guest has expressed an ideal in:

> He has not sowed who gathers gold,
> Nor has he served whose life is told
> In selfish battles he has won
> Or deed or skill that he has done;
> But he has served who now and then
> Has helped along his fellow men.

Sponsorship of a program of lay health education requires no apology or explanation.

Chief interest is now centered in inspiring county societies to initiate a series of local health talks for the public. A committee should be placed in charge. The coöperation of lay organizations should be secured. Publicity should be obtained through the local press and by means of announcements in schools, churches, and in other meetings. Dates should be determined for a series of three to six meetings at intervals of two to four weeks. Assistance in obtaining speakers will be rendered by the state headquarters office. A little push, energy, and work will inaugurate the program in your county. Will you bring this about?

* * *

November Elections

Before the next issue reaches you the November national and state elections will have taken place. Our political interests are not pledged to any party or to party candidates. Our foremost interest is to bring about the exercising of every member's franchise right—to cause him to go to the polls and vote. Our next interest is to urge every member to become informed as to the ability and sincerity of every candidate and to know the purpose and necessity of every special measure or initiative and then to vote in accordance with his best beliefs and judgment. Every voter should aid in securing the election of the most capable candidates and the passing of sound legislation. Entering the voting booth in that spirit will result in the securance of dependable, truthworthy legislators and governmental officials.

Elections record the voice of the people. Record your voice by voting intelligently and advisedly.

* * *

Public Health Institutes

The San Diego Exposition closed its gates the night of September 9. By actual count on the last day, over 10,000 persons visited the Hall of Medical Science. Records reveal that the Hall of Medical Science attracted thousands of people. Its attendance records were exceeded only by the number who visited the Transportation Building. A detailed report on the Hall of Medical Science is being prepared by the committee and will be submitted in the near future.

Sponsorship and supervision of the Hall of Science by the San Diego County Medical Society and the California Medical Association was a major activity these past nine months in our Association's program of public health education and welfare.

We now enter upon our second major activity—the conducting of a series of Public Health Institutes in selected localities in our State with the assistance of county societies and auxiliaries.

The arrangements have been made to conduct Public Health Institutes in Monterey, October 7 to 10; Santa Barbara, October 22, 23, and 24; San Francisco, October 14 to 17. Our Association exhibits on heart, cancer, tuberculosis, diet, preventive medicine, maternal welfare, appendicitis, serology, medical education, smallpox, and plastic surgery will be supplemented by local exhibits from health departments, hospitals, clinics, dairy and food departments, dentistry, nursing and local welfare organizations. These institutes are open to the public. No admission is charged. A series of health talks are given. By these means visualized education on individual health welfare is imparted. Sound public opinion is created and public benefit ensured.

Other bookings will be made at the request of county societies. May it be suggested that your county society sponsor a Health Institute in your community?

* * *

Don't Sign!

1. Until you have read and understand all the clauses of a lease.
2. Until you have included a clause in the lease that in the event of your death your administrator has the option of terminating the lease on thirty-day notice.
3. A note until the maker has secured you as endorser against loss if payment is demanded from you.
4. A trial order unless you are certain that the order can be canceled without cost to you.
5. A petition until you know what the petition contemplates.

6. A certificate until you are possessed of facts to substantiate it.
7. A bond until you understand the liability you are assuming.
8. Don't sign a check for more than your deposit balance.
9. Don't sign a receipt until you have received that which you acknowledge as having received.
10. Don't sign a "power of attorney" unless you are fully informed as to the scope and extent of that power.

Foolish Dont's, some will say. Nevertheless, many an individual has paid dearly because he was careless in not heeding such simple "Dont's"

* * *

A Suggestion Applicable to Your Community

Officers of the Chicago Medical Society report a tremendous amount of interest and educational results in their window display in one of the large department stores in the loop district. The store management has placed one of its large display windows at the disposal of the county society. Each week some health subject is covered by this display, and facts about medical truths are visualized to the passing throng. Time and labor are required to build these exhibits. Members of the society under the guidance of a committee prepare these educational exhibits that daily carry their story to passing thousands. Some of our metropolitan societies will do well to undertake a similar activity. Even in the smaller communities a sympathetic merchant could be induced to proffer a display window for several weeks. Try it!

* * *

Proposed Legislation

It cannot be stressed sufficiently that members should refrain from expressing opinions or subscribing support in legislative proposals until such legislation has been reviewed by the Committee on Public Policy and Legislation and its recommendations have been received. Marked differences of opinions is capitalized by proponents of undesirable legislation. Such a situation should be avoided and can be avoided if members and county societies will conform to this recommendation.

Back of some legislative proposals hidden motives exist. Innocent they seem to be on first or outward appearances, but when analyzed they involve and supersede present satisfactory provisions. Upon application untoward and undesirable conditions are established that hasty approval failed to detect, and had they been known, or had all the ramifications been exposed, endorsement would not have been pronounced and opposition to enactment would have been made. Consequently the advice is repeated, refrain from endorsing and supporting proposed legislation until our Association's attitude is determined.

COMPONENT COUNTY MEDICAL SOCIETIES

SACRAMENTO COUNTY

The regular meeting of the Sacramento Society for Medical Improvement was held in the Auditorium, Twenty-ninth and L streets, on Tuesday evening, September 15, at 2:30 o'clock.

Dr. Edmund Butler of San Francisco was guest speaker, and his topic was *Injuries of the Chest and Abdomen That May Cause Early Death—Diagnosis and Treatment.*

Attention was called to the following resolution, passed at the July 14 meeting of the board of directors of the Sacramento Society for Medical Improvement:

WHEREAS, The By-Laws of the Constitution and By-Laws of the Sacramento Society for Medical Improvement as provided in Chapter VIII, Section VII (b), are as follows:

"Physicians shall not become or remain associated or identified with any corporation, organization, group or individual, medical or lay, except those approved by the Board of Directors of the Sacramento County Medical Society, resorting to or making use of direct advertising to the public for business of a medical or therapeutic nature, or having to do with the diagnosis, care or treatment of the sick or injured, the maintenance of health, or the prevention of disease"; and

WHEREAS, The Mutual Benevolent Health Society is an organization engaged in the practice of medicine; therefore

Resolved, The Board of Directors disapproves of this organization.

NORRIS R. JONES, *Secretary.*

⁂

SAN JOAQUIN COUNTY

The regular monthly meeting of the San Joaquin County Medical Society was held Thursday, September 3, in the Medico-Dental clubroom, at 8:15 p. m., President T. C. O'Connor presiding.

The regular meeting was preceded by the customary supper meeting at the Hotel Wolf at which ten members were present. The paper at the supper meeting was presented by Dr. H. J. Bolinger of Lodi, who talked on *Psychoanalysis From the Viewpoint of the General Practitioner.*

The petition of Dr. H. Rixford for membership in the San Joaquin County Medical Society being passed on favorably by the Admissions Committee, and there being no objection from the floor, he was declared a member. The petitions of Doctors D. Belts and R. A. Greenman were presented and referred to the Admissions Committee.

A representative of the P. T. and T. Co. and Miss Huxford of the Logan Business Bureau spoke on the advisability and cost of installing a physicians' exchange in Stockton.

A communication from George E. Katz, foreman of the San Joaquin County Grand Jury, concerning the adoption of the charter form of government for San Joaquin County, was read.

The paper of the evening was presented by Dr. Charles Mathé of San Francisco, who gave a talk, illustrated by many lantern slides, on *Diagnosis and Treatment of Obstructive Lesions of the Kidney.* After the conclusion of this paper he presented two reels of moving pictures taken on the sixth congress cruise of the Pan-American Medical Association to Rio de Janeiro in 1935. Both the paper and the moving pictures caused considerable discussion and questions from the floor.

There being no further business to come before the Society, the meeting was adjourned at 10:45 p. m. and refreshments were served.

G. H. ROHRBACHER, *Secretary.*

⁂

SANTA BARBARA COUNTY

A special meeting of the Santa Barbara County Medical Society was held at the El Paseo, Monday, August 24.

Those present were: Santa Barbara Councilors Freidell, Gray, and Clark; Doctor Ullmann, state district councilor; and Doctor Eaton, secretary of the Council.

This meeting was celled at the request of a member of the Council to consider the propriety of appointing a committee to investigate the charges preferred against a physician, not a member of the society.

After discussion, a motion was made by Doctor Clark, seconded by Doctor Gray and unanimously carried, that any action in this matter is not properly any business of the Society.

Doctor Freidell suggested that some action be taken to require a response from the membership to the questionnaires recently forwarded.

A motion was made, seconded and carried, that Dr. Harold Kahn of Santa Maria be recommended for membership to the Society, provided a favorable report is received from the state secretary.

✓ ✓ ✓

The regular meeting of the Santa Barbara County Medical Society was held Monday evening, September 14, at Bissell Auditorium, President Gray presiding.

Dr. C. T. Roome gave a very interesting and instructive paper upon *Aseptic Meningitis*, which was discussed by Doctor Koefod. Doctor Roome also commented upon the local infant mortality rate, and emphasized the necessity of stating correctly the primary cause of death when completing death certificates.

Mr. Charles A. Son of Los Angeles gave a very instructive talk upon the *Problems of the Industrial Acci-*

dent Commission, urging closer coöperation by the profession with the Commission.

Mrs. Hunt, president of the Woman's Auxiliary, spoke concerning the *Public Health Institute*, to be held in Recreation Center the latter part of October, and which is being sponsored by this organization. As the Society desired to give financial aid to this project, a motion was made, seconded and carried, that each member of the Society be assessed one dollar.

President Gray announced that the Visiting Nurses' Association had established an hourly nursing service at very reasonable rates.

Doctor Robinson, chairman of the Insurance Committee, gave a most complete and comprehensive report of the activities of this committee, with their recommendations, which upon motion, duly carried, was accepted and ordered attached to these minutes.

Doctor Baird invited the Society to hold the October meeting in Santa Maria, which was accepted.

Doctor Freidell reported the proceedings of the Council meetings, and the Society confirmed the action of the Council, that a committee be appointed to investigate the merits of a malpractice suit.

Other committee chairmen had no reports.

William H. Eaton, *Secretary*.

⁂

SOLANO COUNTY

The Solano County Medical Society held its first meeting after the summer recess, Dr. Joseph Tillotson of Woodland being the guest speaker. The meeting was well attended for the first meeting, and the subject, *Fractures and the Causes of Poor and Fibrous Union* was well received. During the discussion many interesting points on treatment were brought out. Dr. A. Lloyd Johnson, recently of Taft, was admitted to membership on a transfer from Kern County.

John W. Green, *Secretary*.

CHANGES IN MEMBERSHIP

New Members (21)

Fresno County.—Earl H. Coleman, Harold John Cooper, Clarence D. Newel, Milton M. Schatz, Albert Hamlet Sweeney.

Los Angeles County.—J. E. Bergmann, Eugene F. Hoffman.

Monterey County.—Lawrence M. Knox, Arthur L. Wessels.

Napa County.—Stanley McClure Deakin.

San Bernardino County.—Edward Mahon.

San Diego County.—James Clarence Anders, Florence Olive Austin, Alfred Henry Byars, George Wilbur Getze, William Buster McGee.

San Luis Obispo.—Lowell Spafford McGraw.

Santa Clara County.—Albert R. Currlin.

Santa Cruz.—R. C. Alsberge, Edwin A. Coats.

Shasta County.—Bertram Lawrence Trelstad.

Transferred (3)

M. Elizabeth Jenkins, from Solano County to San Francisco County.

A. Johnson, Lloyd, from Kern County to Solano County.

Edwin Wilton Thomas, from San Joaquin County to Shasta County.

In Memoriam

Duffield, William. Died at Los Angeles, September 9, 1936, age 70. Graduate of the University of Pennsylvania School of Medicine, Philadelphia, 1893. Licensed in California in 1900. Doctor Duffield was a member of the Los Angeles County Medical Association, the California Medical Association, and a Fellow of the American Medical Association.

Pure white marble has replaced wooden monuments that formerly were in place. Amongst crosses are many "Stars of David" (Jewish).

OBITUARY

Shadworth Beasley

1876-1918

The inscription on a marble tombstone in the Meuse-Argonne cemetery reads, "Shadworth O. Beasley, Major, Medical Department, California, October 14, 1918, D.S.C." On the anniversary of his death it is fitting that we should pause and do homage to the memory of a real man, a fine physician, and a brave American, whose life was devoted to helping others and who made the supreme sacrifice while rendering aid to the wounded under fire near Cierges, France.

The record reads: "Major Beasley was killed in action October 14, 1918, about 8 a. m., on Hill 253, about two kilometers northwest of Cierges, France. He had just returned from the hospital to duty the day before, where he was under treatment for the grippe. Seeing a soldier fall into a shell hole after being struck by fragments of a high explosive shell, he left his shelter to go to the aid of the wounded man. While supervising the carrying of the wounded man back to the aid station, another high explosive shell burst directly on the aid party, mortally wounding Major Beasley in the right hip and abdomen. First aid was administered by the sergeant and litter carrier, but the Major was beyond medical aid, and died about ten minutes after being wounded. He remained conscious up to the moment of his death."

Previously, Major Beasley had a long and honorable career in the Philippine wars and later in Serbia. At the time of the World War he was assistant clinical professor of obstetrics and gynecology at Stanford University Medical School and member of the San Francisco County Medical Society. He went into the Army and overseas early, seeing much active service.

The citation under which Major Beasley was awarded a Distinguished Service Cross, reads as follows: "For extraordinary heroism in action near Petit Bordeau Woods, France, July 14-16, 1918. During the entire action, Major Beasley braved the danger of continuous shell fire by constantly searching for wounded and administering treatment."

There are many California boys resting in this beautiful place.

Recently, while motoring through Europe we stopped at the Meuse-Argonne cemetery and had the privilege of visiting "Shad's" grave and taking these photographs. Originally there were twenty-five thousand bodies in this beautiful place, but ten thousand have been returned to America. Many thousands more remain in various parts of France. When one contemplates this and reviews the world situation and observes the attitude toward us of some of our European friends, one cannot help asking "was it worth the sacrifice"?

HARRY E. ALDERSON, M. D.

THE WOMAN'S AUXILIARY TO THE CALIFORNIA MEDICAL ASSOCIATION†

MRS. ANDREW J. THORNTON.............................President
MRS. ROBERT M. FURLONG...Editor and Chairman of Publicity

A. M. A. Convention Gleanings: Report by the President

Dear Auxiliary Members:

Thursday, May 9, was the day and 8 p. m. the hour toward which all my plans had been shaping for a fortnight. . . .

I reached Kansas City late Saturday night. The first person to greet me in the dining room Sunday morning was Mrs. Rogers N. Herbert, our national president.

Sunday afternoon, May 10, a tea honoring Mrs. Herbert was tendered the National Board by members of the Jackson County and the officers of the Wyandotte and Clay County auxiliaries. . . .

Baltimore Hotel, Kansas City, Missouri, was the official headquarters of the fourteenth annual convention of the Woman's Auxiliary to the American Medical Association, which convened from May 11 to 15. . . .

I think I gained most benefit from the deliberations of the National Board, since there was more opportunity for frank discussion of problems and policies in this smaller group than during the general sessions of the convention.

The problem of coördinating the work of local, state, and national bodies was much discussed. State presidents were urged to impress upon their officers the importance of coöperating with the National Auxiliary in two particulars: by sending their addresses to the corresponding national chairman, and by answering all correspondence promptly. Silence is baffling to a chairman trying to assemble data necessary to make her own records complete.

Mrs. James D. Lester, our energetic *Hygeia* chairman, was asked many difficult questions regarding *Hygeia* subscription rates. There seemed to be a general feeling that a larger number of subscriptions could be obtained through the efforts of the auxiliaries if a more definite price schedule were established. . . .

Perhaps this is the point to pass on a word of advice from National regarding organization work. It is this: that care should be taken to have sufficient enthusiasm and interest aroused before an auxiliary is formed so that a permanent organization will be assured.

The problems peculiar to the small auxiliary were discussed most sympathetically. The consensus of opinion was that these groups are asking too much of themselves. They justify themselves by being organized and ready for the opportunity to serve the cause of better public health and scientific medicine whenever it arises.

For a number of years the revision of the Constitution and By-Laws of the Woman's Auxiliary to the American Medical Association has been in progress. Since it embodied several changes in procedure which required intensive study before final action could be taken, it was referred to the Revision Committee for recommendation next year.

Mrs. Eben J. Carey, treasurer, reported the new accounting system a great improvement since it has simplified the work of local officers and provided them a permanent record of membership. The system is fully explained in the new Handbook, and I urge all county treasurers to familiarize themselves with it. Copies of the Handbook may be obtained from the chairman of supplies, Mrs. Lucius Cole, 1117 North Lathrop Avenue, River Forest, Illinois. The price is forty cents.

Mrs. William Hibbitts, historian, had prepared an excellent map in folder form. . . .

In concluding my report of the Monday sessions, I want to stress three ways to coöperate with the National this year:

First: By answering all communications promptly and fully.

Second: By keeping records of all *Hygeia* subscriptions secured.

Third: By carrying on Mrs. Long's three-point program, which follows:

1. The continuation of the Public Relations Educational Program through health programs, health institutes, and essay contests.
2. That auxiliaries continue coöperation with local Parent-Teacher groups in their health programs by advising periodic health examinations of school children in the office of the family physician in preference to mass clinics.
3. The promotion of *Hygeia* exhibits at county and state fairs, with Auxiliary members serving as hostesses and distributing American Medical Association literature.

The formal opening of the convention was at nine o'clock, May 12, in the Francis I room of the Hotel Baltimore. Forty-four board members, sixty-four delegates, and sixteen alternates responded to roll call.

I shall mention only a few highlights from the sessions of the convention, but strongly recommend that you read the reports of the state presidents when they are printed. They were stimulating and a revelation of the growth in knowledge and usefulness of our membership.

Mrs. Rogers N. Herbert, in her annual report declared the Auxiliary needs greater appreciation from the doctors and greater unity between county, state, and national bodies.

Mrs. Augustus Kech of Pennsylvania was named president-elect.

Now as to the part California played in the convention. Six women responded to roll call, one board member, and five delegates. California ranked third in membership with 1,080 paid-up members. We received honorable mention for the increase in number of subscriptions to *Hygeia* over the previous year. I was proud of the report that California stood first in number of new counties organized. We reported five and Mississippi four.

Your delegates were of service on convention committees. Mrs. W. H. Sargent, Mrs. James F. Percy, and Mrs. Andrew J. Thornton were named on the elections, the nominating and the credential committees, respectively.

Finally, I am happy to report that California will have two representatives on the National board next year. Mrs. Philip S. Doane was elected third vice-president, and to Mrs. James F. Percy were entrusted the difficult problems to which the Chairman of Revisions has fallen heir.

At the Tuesday, Wednesday, and Thursday luncheon hour we were instructed and entertained by three guest speakers: Dr. W. W. Bauer, director of public health for the American Medical Association; Dr. Perry Bromberg, professor of clinical urology, Vanderbilt University; and Tom Collins, Kansas City humorist.

Doctor Bauer was the keynote speaker of the convention and discussed the relation of the Woman's Auxiliary to his department.

Dr. Perry Bromberg's subject was *Trends in Modern Medicine*. He considers public health conservation the most important function of government. He described the types of socialized medicine practiced in Europe. Physicians in England, Germany, and elsewhere reported services rendered by physicians under state medicine are not as efficient as in private practice. Because of lack of time the physician gives less personal service. A comparison of health conditions in the United States with those in

---

† As county auxiliaries of the Woman's Auxiliary to the California Medical Association are formed, the names of their officers should be forwarded to Mrs. Robert M. Furlong, chairman of the Publicity and Publications Committee, Linden Lane, San Rafael. Brief reports of county auxiliary meetings will be welcomed by Mrs. Furlong and must be sent to her before publication takes place in this column. For lists of state and county officers, see advertising page 6. The Council of the California Medical Association has instructed the editor to allocate two pages in every issue for Woman's Auxiliary notes.

European countries shows that the United States ranks first in every form of medical practice, except the care of industrial accidents, and maintains the highest grade of health for its workers of any people in the world.

The witty, laugh-producing talk Thursday noon by Tom Collins furnished us a well-earned half-hour of relaxation. His subject was *The Care and Treatment of Husbands and Wives.*

The hospitality of the Kansas City women was expressed graciously and bountifully. Drives on two days through the beautiful parks and residence districts were supplemented by teas in private homes.

The appointments of the dinner on Monday night, honoring the founders, officers, and presidents of the auxiliaries of Kansas and Missouri, were particularly beautiful. The function was held at the Kansas City Country Club.

The bring-your-husband dinner was attended by eight hundred persons. The program on this occasion was elaborate, consisting of nine musical, dramatic, and dancing numbers. These were interspersed by assembly singing of clever odes written by Mrs. Sam Roberts, a local physician's wife. Here is a sample (tune, "Home on the Range"):

Oh, Doctor, come home to the children and me,
And call on us—we need you, see!
Set the old black bag down at its place on the floor
Get some rest, let us meet you once more.

Chorus

Home—home from your calls,
Where no fear and alarm on you falls,
With your thumb by your side,
On no pulse must it ride.
We'll plug phones and in peace all abide.

I regard my days in attendance at the convention as an intensive training course in preparation for my work this year. Thank you for the privilege.

Sincerely yours,
ADA COY THORNTON.

* * *

State Auxiliary News

A meeting of the State Board of Directors of the Woman's Auxiliary to the California Medical Association was held at the Del Mar Club in Santa Monica on September 11, 1936. A very good attendance proved the interest with which the work of the year will be carried on. Mrs. Andrew J. Thornton, state president, presided at this meeting.

Problems of the individual auxiliaries and plans for unifying the State Auxiliary were discussed.

Mrs. John Hunt Shephard, convention chairman, urged the members of all the auxiliaries to make reservations for the annual session at Del Monte as soon as possible. This meeting is held in May, 1937, and a large attendance is expected.

A resolution honoring the memory of Dr. William Duffield, our founder, was read. Doctor Duffield was appointed by the California Medical Association to organize a Woman's Auxiliary. On May 8, 1929, during the convention of the California Medical Association then in session at Coronado, he called together the physicians' wives who were present and perfected the organization of the Woman's Auxiliary. Doctor Duffield was untiring in his efforts to make the Auxiliary a success and gave much encouragement and valuable advice to its officers during the early years of its existence.

The following resolution was adopted by the State Board in his memory:

MEMORIAL RESOLUTION

WHEREAS, Our founder and ever faithful counselor and guide, Dr. William H. Duffield, has been called home, having departed this life September 9, 1936; and

WHEREAS, His absence from his accustomed place among us will be keenly felt by those of us who must carry on without him; therefore be it

Resolved, That the Board of the Woman's Auxiliary to the California Medical Association in official meeting assembled September 11, 1936, at Santa Monica, California, pause in its deliberations for one minute, standing with bowed heads, in honor of his memory and to express to his family the deepest regrets and sympathy on behalf of the State Auxiliary, in token of which be it further

Resolved, That a copy of this resolution be presented to the family, a copy spread upon the minutes of this Association, and a copy furnished to CALIFORNIA AND WESTERN MEDICINE.

Committee:
MRS. JAMES F. PERCY
MRS. CLIFFORD A. WRIGHT
MRS. PHILIP S. DOANE

MARGARET M. FURLONG,
Chairman of Press and Publicity.

* * *

County Auxiliary Reports

San Diego County.—The regular meeting of the Auxiliary to the San Diego County Medical Society was called to order by our new president, Mrs. F. G. Lindemulder. A buffet luncheon was served beside the pool of the Hotel del Coronado beach and Tennis Club.

This was a social meeting. The secretary's minutes and the treasurer's report were dispensed with.

Mrs. Paul Wedgewood reported that the treasurer's books had been audited and were found in good order.

Mrs. Elliott Colby gave a short talk on the Community Chest, reminding each member to do her part.

Mrs. Lindemulder called attention to the payment of delinquent dues and that work had been started on the new year book.

The new board and chairmen of the standing committees were introduced by the president.

Mrs. Hiram Newton introduced guests of the day.

After the meeting adjourned, the remainder of the afternoon was spent in visiting and swimming.

ELIZABETH R. BELFORD, *Secretary.*

* * *

San Francisco County.—The first meeting of the coming year of the Woman's Auxiliary to the San Francisco Medical Society took the form of an enjoyable luncheon held at the Western Women's Club on Tuesday, September 15, with Mrs. J. C. Geiger presiding. The attendance was most satisfactory, the East Room of the Club being filled to capacity with a group of eager, earnest women.

Our guest speaker was the secretary of the California Medical Association, Dr. Frederick C. Warnshuis, who addressed us on *Organized Medicine.* Doctor Warnshuis expressed his approval of women's auxiliaries to the medical societies, urging the women to help their husbands by fostering public health meetings in Parent-Teacher Associations, women's clubs and like organizations, in order to acquaint the general public with necessary information along this line.

The Auxiliary is growing rapidly, over twenty-two new members being added to the group since last spring. Not only are we growing in numbers, but in enthusiasm as well, as is being shown by the interest registered in the various activities of the group.

Monthly, on Wednesday mornings at ten o'clock, at the headquarters of the San Francisco County Medical Society, 2180 Washington Street, the following round tables will be held:

First Wednesday—Cause and Cure for War, Chairman Mrs. Fred H. Zumwalt.

Second Wednesday—Social Welfare and Public Health, Chairman Mrs. Frank J. Rodin.

Third Wednesday—History of Medicine, Chairman Mrs. Julius Sherman.

Fourth Wednesday—Legislation, Chairman Mrs. Rodney A. Yoell.

Although the importance of social life in our group is recognized, it may be readily discerned from our program that we aim to take a definite place in the more serious life of our community.

AMY S. ZUMWALT, *Chairman of Publicity.*

Happy is the man who understands his capacities and his limitations. Happy is the group which has so well defined its functions that it invades the province of no other group. Wise is the man, and wise is the group, who, with Plato, can say, "What I do not know, I do not think I know."

MISCELLANY

Under this department are ordinarily grouped: News Items; Letters; Special Articles; Twenty-five Years Ago column; California Board of Medical Examiners; and other columns as occasion may warrant. Items for the News column must be furnished by the fifteenth of the preceding month. For Book Reviews, see index on the front cover, under Miscellany.

NEWS

Coming Meetings

American Medical Association, Atlantic City, New Jersey, June 7-11, 1937. Olin West, M. D., 535 North Dearborn Street, Chicago, secretary.

California Medical Association, Del Monte, May 2-5, 1937. F. C. Warnshuis, M. D., 450 Sutter Street, San Francisco, secretary.

* * *

American College of Surgeons, Philadelphia, October 19-23, George W. Crile, M. D., 40 East Erie Street, Chicago, Chairman, Board of Regents.

American Public Health Association, New Orleans, October 20-23. Reginald M. Atwater, M. D., 50 West Fiftieth Street, New York, executive secretary.

Interstate Postgraduate Medical Association of North America, St. Paul, October 12-16. W. B. Peck, M. D., 27 East Stephenson Street, Freeport, Illinois, managing director.

Oregon State Medical Society, The Dalles, October 8-10. Morris L. Bridgeman, M. D., 1020 S. W. Taylor Street, Portland, secretary.

Medical Broadcasts*

The American Medical Association broadcasts have been discontinued for the summer months. A new series is under consideration for the autumn and winter of 1936-1937.

* * *

San Francisco County Medical Society.—The radio broadcast program for the San Francisco County Medical Society for the month of October is as follows:

Tuesday, October 6—KYA, 6 p. m.
Tuesday, October 13—KYA, 6 p. m.
Tuesday, October 20—KYA, 6 p. m.
Tuesday, October 27—KYA, 6 p. m.

* * *

Los Angeles County Medical Association.—The radio broadcast program for the Los Angeles County Medical Association for the month of October is as follows:

Saturday, October 3—KFI, 9 a. m. Subject: The Road of Health.
Saturday, October 3—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, October 6—KECA, 10:30 a. m. Subject: The Road to Health.
Saturday, October 10—KFI, 9 a. m. Subject: The Road of Health.
Saturday, October 10—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, October 13—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, October 17—KFI, 9 a. m. Subject: The Road of Health.
Saturday, October 17—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, October 20—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, October 24—KFI, 9 a. m. Subject: The Road of Health.
Saturday, October 24—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, October 27—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, October 31—KFI, 9 a. m. Subject: The Road of Health.
Saturday, October 31—KFAC, 10:15 a. m. Subject: Your Doctor and You.

Air Line Transportation for Infants.—Transportation of infants by air is increasing, the latest example being the case of three months old Martin Thomas, son of Dr. and Mrs. Thomas Ferwerda of the Naval Hospital at the Navy Yard in Brooklyn.

A husky, eight-pound boy, only three months old, he was the youngest, smallest child ever to fly from coast to coast without its parents, according to Air Line officials.

Los Angeles County Hospital.—Item from the Los Angeles *Herald-Express* (September 3):

"Le Roy R. Bruce, assistant superintendent of county charities for the last three years, today was appointed assistant executive superintendent of General Hospital at a salary of $5,000 per year by Rex Thomson, county superintendent of charities. The appointment was approved by the Civil Service Commission.

"Bruce will succeed G. W. Olson, who recently submitted his resignation, to become effective October 1. Olson will take over the post of superintendent at the Queen of the Angels Hospital. Before entering county service, Bruce was deputy director of state institutions of California for four years."

Hearing Tests Aid Classroom Work at State University.—In many instances, suspected contrariness, day dreaming, or plain laziness are being eliminated at the University of California as the causes of lack of concentration and lax study habits among students. A health survey made by the Cowell Memorial Hospital on the University campus has determined that physical defects, combined with sensitiveness in a number of instances are the real reasons for low grades, and there is an immediate improvement where these defects are corrected or properly understood.

A test of 4,003 students in the hospital determined that no less than 587 were suffering from defects of hearing which could have affected their scholastic work. Of the latter number, 308 were men and 279 women. In the total group, 101 were suffering the loss of twelve or more sense units out of a possible 100 such units. . . .

State Health Officers' Meeting.—The League of California Municipalities held its annual convention on September 9 and 10 in the City of Santa Monica. The Health Officers' Section had meetings on both days. Among the papers presented by members of the medical profession were the following:

President's Address—Dr. C. M. Burchfiel, Santa Clara County Health Officer.

Public Health in California—Dr. Walter M. Dickie, Director, California State Department of Public Health.

The Social Security Act in Relation to the Health Department—Surgeon Fred T. Foard, United States Public Health Service.

The Next Steps in Public Health—Dr. George Parrish, Los Angeles City Health Officer. Dr. George H. Kress, Member, California State Board of Public Health, discusser.

Venereal Diseases—Dr. George M. Stevens, Epidemiologist, Los Angeles City Health Department. Dr. Lee A. Stone, Madera County Health Officer, discusser.

The Use of Immunobiologic Principles in the Prevention and Control of Civilization Diseases—Dr. Karl F. Meyer, Director, Hooper Foundation for Medical Research.

A Review of Twenty Years' Experience in County Health Work—Dr. J. L. Pomeroy, Los Angeles County Health Officer.

An Original Method for Differentiation of Staphylococci Involved in Food Poisoning—Dr. R. V. Stone, Director, Bureau of Laboratories, Los Angeles County

---

* County societies giving medical broadcasts are requested to send information as soon as arranged (stating station, day, date and hour, and subject) to California and Western Medicine, 450 Sutter Street, San Francisco, for inclusion in this column.

Health Department. Dr. W. H. Kellogg, Chief, Division of Laboratories, State Department of Public Health, discusser.

The Epidemiology of Tuberculosis—The Health Officer's Opportunity—Dr. Reginald H. Smart, Constultant on Tuberculosis, Los Angeles County Health Department. Dr. K. H. Sutherland, Orange County Health Officer, discusser.

On Thursday the banquet of the Health Officers' Section was held at the Grand Hotel, Dr. George H. Kress acting as toastmaster. The address of the evening was made by Dr. Robert Gordon Sproul, president of the University of California, who spoke on the subject, "The State University in Relation to the Public Health."

New York Automobile Toll Reduced.*—The number of motor vehicle accidents and the number of persons killed and injured were reduced in the first six months of 1936, as compared with the corresponding period of 1935, the Bureau of Motor Vehicles recently reported. The number of accidents was 34,159, compared with 35,503; the number of persons killed 1,047, compared with 1,199, and the number injured 42,867, compared with 44,609. Of the accidents, 16,159 were collisions with pedestrians, 13,031 collisions with other cars. Of 47,418 motorists involved, 295 were listed as intoxicated and 32 as having a physical defect. Of 16,640 pedestrians involved, 470 were said to have been intoxicated, 97 had physical defects and 819 were confused by traffic.—*J. A. M. A.*, September 19, 1936.

Traffic Kills Seven in Los Angeles.*—Under the above caption, the Los Angeles *Herald-Express* of Monday, September 21, 1936, printed the following item:

"Seven more persons were killed and scores injured in traffic accidents reported throughout the county during the past twenty-four hours and a dozen drivers who figured in collisions were arrested on suspicion of drunk driving.

"Official records in the coroner's office today disclosed the distressing fact that 689 persons have lost their lives in traffic accidents in Los Angeles County since the first of the year. Of this number, 352 were killed in the city. Injuries in the city proper to date total 11,050. In the county, 2,697 persons have been injured so far this year."

Summary of Mortality from Automobile Accidents*. The United States Bureau of the Census announces that during the four weeks ending August 29, 1936, eighty-six large cities in the United States reported 665 deaths from automobile accidents. This number (665) compares with 611 deaths during the four weeks ending August 31, 1935. Most of these deaths were the result of accidents which occurred within the corporate limits of the city, although some accidents occurred outside of the city limits.

For comparison, the number of deaths due to automobile accidents within city limits is desirable. Such figures are available for the four-week period ending August 29, 1936, and for the corresponding four-week period of 1935 for all of the eighty-six cities, the four-week figure in 1936 being 484 as contrasted with 441 for the corresponding four weeks in 1935.

For the 52-week periods August 29, 1936 and August 31, 1935, the totals for the cities were respectively 8,436 and 8,997, which indicate a recent rate of 22.7 per 100,000 population as against an earlier rate of 24.1 or a decrease of 6 per cent in the rate during the year.

Four cities reported no deaths from automobile accidents for the last four weeks, and one city reported no deaths from automobile accidents for the corresponding period of 1935.

For the last four-week period reports as to whether deaths occurred from automobile accidents within city limits or outside were received from all of the eighty-six cities reported. In these cities in this four-week period, the total number of deaths from automobile accidents was 665, but only 484 of these were due to accidents within city limits.

Health Exhibit This Year in Wide Range of Health Work.—The *Ohio Health News* states:

"This year's health exhibit at the Ohio State Fair will provide complete coverage of the activities of the State Department of Health, with special emphasis on the broader scope of the work in maternal and child hygiene, milk sanitation, occupational diseases, and public health nursing. All divisions will be represented in the array of charts, graphs and statistical tables, and other features will be exemplified in models, equipment, and photographic displays. An attractive gallery of child hygiene posters has been provided. Samples of literature and lists for visitors to check their needs will be at hand.

The exhibit will be housed in a new location, as last year's site was not available.

Urologic Clinic Before Alameda Society.—Dr. Elmer Hess, one of the country's outstanding urologists, on Thursday, August 13, gave a very interesting clinic on urologic surgery to the Alameda County Medical Society.

American Medical Association Conference of State Association Secretaries and Editors.—The annual conference of state medical association secretaries and editors will be held in Chicago on Monday and Tuesday, November 16 and 17, 1936. The secretary of the American Medical Association has mailed notice of the meeting to all state medical associations.

State University and Stanford in New Drive Against Tuberculosis.—A ten-year program to end any incidence of tuberculosis that may be found in the student bodies of the University of California and Stanford University, and to give impetus to the general drive against the "white plague" in the State, has just been announced by Dr. R. T. Legge, University of California physician, and head of the Cowell Memorial Hospital on the University of California campus.

The plan, now in active operation, includes the examination of every freshman student through intradermal, x-ray, or fluoroscope test for indications of tuberculosis in any and every form. This is in addition to the regular physical examination given each student. Those entrants having active cases of tuberculosis are hospitalized, as usual, while the quiescent or arrested cases are examined periodically, their contacts closely watched, and a regimen of medical treatment laid out for them.

An examination of 1,829 new students on the Berkeley campus at the time the plan was inaugurated, revealed an extremely low incidence of cases of present and suspected activity, there being but three active histories possible, but the number of those disclosing healed lesions was 433. Of the cases of all classifications detected, 35 per cent were men and 28 per cent women. . . .

University of California Experiments Show Food Extract May Cause Cataracts.—The baffling problems surrounding the cause of cataracts in the eye may be a step nearer solution as a result of experiments carried on by Dr. Agnes Fay Morgan, chairman of the Department of Household Science, and Bessie B. Cook, graduate student, in the University of California. In human subjects the drug dinitrophenol, which is presumed to have some efficacy as a fat reducer, is also presumed to produce cataracts. Experiments on subjects other than human, made by the University, now tend to further the claim that certain dietary elements may also be responsible, and that the element of light may not be as important a cataract producer as it has been figured in the past.

In the experiments, conducted by Doctor Morgan and her associate, it was shown that a diet running high in milk sugar or lactose tended to produce cataracts. In a report to the Society for Experimental Biology, they state:

"The delay in, or interference with complete absorption accompanying the presence of large amounts of lactose or galactose in the intestine, and the frequent gastro-intestinal absorption difficulties in clinical conditions associated with vitamin G deficiency, for example, pellagra, pernicious anemia, and sprue, offer a possible common attack upon the problem. The present study was planned to test the bearing of such absorption disturbances upon the production of cataract, of dermatitis and of growth abnormality. . . .

Californian Goes to Queens Hospital, Honolulu.—News item from the Los Angeles *Herald-Express:*

G. W. Olson, Aide at Los Angeles Hospital Takes Hawaii Post

"Recognized as one of America's leading authorities on hospital management, construction and maintenance, G. W. Olson, assistant superintendent of the Los Angeles General Hospital, today accepted an offer to become the superintendent of the Queens Hospital in Honolulu.

"Olson today tendered his resignation, to take effect October 1, when he expects to leave for his new post. He has been assistant superintendent of the institution since 1932.

"Prior to that he was superintendent of the California Hospital, in the construction of which he was active. He has been identified with hospitals in executive capacities for twenty-five years."

On Tuesday noon, September 15, members of the Swedish and Nordic clubs of Los Angeles and the members of the attending staff of the California Hospital gave a luncheon in honor of Mr. Olson at the University Club of Los Angeles, Mr. Ritz Heerman presiding as toastmaster.

On behalf of the members of the attending and administrative staffs of the California Hospital, Dr. George H. Kress presented to Mr. Olson two traveling cases.

The Sixty-Fifth Annual Meeting of the American Public Health Association. — The American Public Health Association will hold its sixty-fifth annual meeting in New Orleans, October 20-23.

More than one hundred separate scientific sessions are listed, engaging upward of three hundred speakers. There are highly specialized programs designed to solve current problems in the fields of administration, nursing, school health work, health education, sanitary engineering, vital statistics, laboratory practice, child hygiene, industrial hygiene, epidemiology. There are programs covering overlapping interests which involve several groups of specialists who come together in joint meetings for common discussion. There are programs broad enough in scope and of sufficient importance to warrant the attendance of the entire Association in general sessions.

Advances in public health is one such general session. Recent advances in administrative technique, in the control of pneumonia, in engineering practice, in health education methods, in laboratory methods, and housing as a public health problem will be presented by qualified experts.

Other general sessions will deal with diphtheria immunization, mental hygiene, mosquito-borne diseases, and professional education.

A symposium on syphilis is featured.

Other symposia include industrial sanitation, milk and dairy products, infant and maternal mortality, enteric fevers, nutritional problems, registration of births and deaths, care of communicable disease in the home, food poisoning, sanitation of eating utensils, intestinal parasites, school-health education, school nursing, business aspects of the health department, and publicity.

The program of the sixty-fifth annual meeting includes the meetings of a number of related organizations which regularly choose the same convention site and dates. They are: The American Association of School Physicians, the Conference of State Laboratory Directors, the Conference of State Sanitary Engineers, the Association of Women in Public Health, Delta Omega, National Committee of Health Council Executives, the State Registration Executives, and the International Society of Medical Health Officers.

On the invitation of the Cuban Government and Florida health authorities, the Association will sponsor an all-expense postconvention tour to Havana via Florida by train, motor, and steamer. Delegates are invited to join the tour.

The American Public Health Association offers a copy of the program, which includes hotel and railroad information, a summary of the postconvention tour and other details concerning the annual meeting to those who write to the Association's office, 50 West Fiftieth Street, New York City.

Donation of Volumes on Anesthesia to University of California Library.—Dr. C. D. Leake, librarian and professor of pharmacology of the University of California Medical School, has given a special collection to the Crummer Medical History Room of items relating to the history of anesthesia. These range from sixteenth century publications of Valerius Cordus (1515-1544), who discovered ether, to autographed signed letters from Dr. Carl Koller, who introduced local anesthesia in 1884. There is included in the collection inscribed volumes of Humphrey Davy and Horace Wells, who discovered the anesthetic properties of nitrous oxid, pamphlets and books dealing with Morton, Long, and Jackson's introduction of ether, material relating to Simpson's work on chloroform, Claude Bernard's, John Snow's, Richardson's and Gwathmey's general work on anesthesia, and correspondence, manuscripts and original documents concerned with recent developments in anesthesia, including ethylene, "amytal," "avertin," "evipal," cyclopropane, divinyl oxid, and Water's carbon dioxid absorption technique, preoperative medication, and the prevention of local anesthetic toxicity. This collection is particularly interesting because of its relation to the scientific work on anesthesia which has been conducted for the past eight years in the pharmacological laboratory of the School.

Recent deposits in the Crummer Medical History Room include a set of diplomas from Dr. Elizabeth Davis from the University of Pennsylvania Medical School in the early part of the nineteenth century.

First Transparent Woman.—Dr. Dean De Witt Lewis, famous surgeon-in-chief of Johns Hopkins Hospital, Baltimore, Maryland, recently unveiled the Camp Transparent Woman before a distinguished gathering of prominent medical authorities, noted scientists and leading public health officials. S. H. Camp, president, S. H. Camp & Company, Jackson, Michigan, brought the Transparent Woman to the United States as his contribution to public health education.

The Camp Transparent Woman is the first and only one in the world, and will shortly leave the New York Museum of Science and Industry for a nation-wide public health educational tour of one hundred cities which is expected to last more than two years. It will be accompanied by a doctor-lecturer, who will introduce the exhibit to the profession, scientists, and public health officers nationally, and to the general public in a series of lectures to which admission will be free. At the close of the tour it will be given to some prominent medical school or museum for permanent exhibition.

William F. Snow, M. D., general director of the American Social Hygiene Association, lecturer of the Columbia University, Teachers' College, formerly president of the National Health Council and health officer of the State of California, stated in regard to the Transparent Woman:

> There is a great need in this country for more health education through visualizing the essential structures and functions of the human body.
>
> Every man, woman, and child should understand the body as a biologic machine and how to run it.
>
> This transparent life-size figure is a splendid teaching model for giving the public quickly and clearly a knowledge of all the organs and their relations, similar to the knowledge gained from visiting a factory and seeing all the parts of an automobile demonstrated. It is by such methods that the people are prepared for subsequent demonstrations and instruction in what to do to conserve health or to assist the physician whom they consult in efforts to regain their health.
>
> I hope this is the beginning of many coöperative activities of science and industry for promoting health and preventing disease.

The International College of Surgeons.—The establishment of Colleges of Surgeons in the principal countries of the world has resulted in a higher standardization of surgery. Not only has it stimulated surgeons to strive for a higher goal, particularly the younger man, but it has also raised the standards of hospitals until it has eliminated a horror against hospitals which was universal for so many years.

It is timely for an International College of Surgeons to be formed. The International Surgical Society has been in existence for some years. It is a highly respected organization, limited in membership, and under the able leadership of Doctor Mayer of Holland has done good work. But it has made no attempt to broaden its field. The International College of Surgeons, however, with headquarters in Geneva, Switzerland, will open its doors to all reputable surgeons, of all countries, who can pass the severe test examination or who, because of outstanding ability, are recognized as of sufficient eminence to be appointed without examination.

Professor Arnold Jirasek of Czechoslovakia was recently appointed president. Professor Albert Jentzer of Geneva was appointed secretary-treasurer general for Europe. We are happy to state that the appointment of director-general was tendered to Dr. H. Lyons Hunt of New York City, who for years held the same position with the American Medical Editors and Authors' Association.

Naturally, everyone is interested in knowing who, of American surgeons, have already been chosen for Fellowship. For obvious reasons it would be untimely to mention them here. A booklet of their names, addresses, and hospital affiliations has already been prepared.

The number of regents and appointed Fellows throughout the world is limited to one thousand. In the list of American and Canadian surgeons recently sent out, are the names of a few hundred of the most prominent surgeons on this continent. If the same intelligence is used for all honorary appointments, the College will have a nucleus of the greatest men in surgery in the whole world.

The creation of an organization of this kind was bound to meet with a certain amount of criticism. We are not unmindful that the American College of Surgeons had to combat such criticism in its formative years. The answer—the acceptance of Fellowship by the outstanding surgeons of this country and Canada. The College must stand or fall by showing its need, by having on its roster those men in surgery who have always had the highest ideals and who have the courage and leadership ability to make a success of any undertaking to which they have lent their names. Naturally, the administration of such an organization must be placed in the capable hands of men who have vision, who are unbiased and who will work with an idealism which will make the College respected. We feel that a right start has been made. The future will tell the rest of the story.

LETTERS

Concerning annual training course for Medical Department Reservists of the Army and Navy.

Headquarters Seventh Corps Area
Office of the Surgeon
Omaha, Nebraska,
September 1, 1936.

To the Editor:—Inclosed herewith is a notice which is being sent to all reserve officers in this corps area announcing the next, or eighth, annual inactive duty training period to be held at the Mayo Clinic for reserve officers of the Army and Navy.

In past years we have had a number of applicants who had seen notices in your journal or in the *Journal of the American Medical Association.*

We should be very glad indeed to have you use this data as a news item or otherwise, as you see fit.

Kent Nelson,
Colonel, Medical Corps, Surgeon.

* * *

Headquarters Seventh Corps Area
Office of the Surgeon
Omaha, Nebraska,
August 12, 1936.

Surg. 353 or (Mayo Foundation) JRH 4000.
Subject: Medico-Military Inactive Duty Training, Mayo Foundation.
To Medical Department Reserve Officers.

1. The eighth annual training course for Medical Department Reservists of the Army and Navy will be held at the Mayo Foundation, Rochester, Minnesota, from October 4 to 17, 1936.

2. This training course was first inaugurated by the Seventh Corps Area at the request of the Mayo Foundation to give training in military medicine to the younger medical men connected with the Foundation. Other reserve officers requested permission to enroll and to take advantage of the opportunity to attend clinical presentations during the morning hours. Such permission was granted and such attendance has become so increasingly popular that it is now necessary to limit the enrollment.

3. The program will follow the plan of the past years. The morning hours will be devoted entirely to professional work in special clinics and study groups. Officers in attendance may select the course they wish to follow from the wide variety of presentations offered. The afternoons and evenings will be devoted to a medico-military program under the direction of the surgeon of the Seventh Corps Area (Army) and the surgeon of the Ninth Naval District (Navy).

4. This training is on an inactive duty status and is without expense to the Government. Enrollment is open to all Army and Navy reservists of the Medical Departments in good standing. Application should be submitted to the surgeon of the Seventh Corps Area, Omaha, Nebraska, or the surgeon, Ninth Naval District, Great Lakes, Illinois. Enrollment is limited to two hundred.

5. The surgeons-general of the Army, Navy, and Public Health Service have signified their desire to attend at least a portion of the course.

Kent Nelson,
Colonel, Medical Corps, Surgeon.

Concerning treatment of dog bites.

Office of
Director of Public Health
City and County of
San Francisco

To the Editor:—I am enclosing copy of a letter to Mr. Albert Payson Terhune, relative to an article appearing in the *Reader's Digest,* August, 1936, entitled "Beware of the Dog." I thought this would be of interest to you.

Sincerely,
J. C. Geiger, M. D., *Director.*

* * *

September 14, 1936.

Mr. Albert Payson Terhune,
c/o Readers' Digest Association,
Pleasantville, New York.

Dear Mr. Terhune:

I am in receipt of a copy of your article "Beware of the Dog," as published in the *Readers' Digest.* It was sent to me by a young woman dog owner, who was formerly a student of science.

Although we agree with your praises of the animal, the statement discussing the possibilities of rabies infection is perhaps misleading. In many communities a real hazard is present in each dog bite due to the endemicity of rabies. Fortunately this condition does not exist in New York City or in San Francisco. It does, however, even today, exist in many other localities.

Furthermore, your advice "to paint the wound with carbolic acid instead of iodine" is rather poor, as the former is quite a real escharotic and dangerous in the hands of the inexperienced, while both are useless in the treatment of rabies. Fuming nitric acid is usually used by the medical profession. Better advice would be to have a physician take charge of the treatment.

Trusting you will understand my motive in writing and assuring you we have enjoyed many of your stories, I am

Cordially yours,
J. C. Geiger, M. D.,
Director of Public Health.

Concerning Proposition 2 on November ballot.

September 14, 1936.

The Members of the Medical Profession, Addressed.

Dear Doctors:—California physicians are hard hit by the new State tax on personal incomes. It is a bad tax for everyone; but the burden falls heaviest on those whose income-producing asset is professional skill and this is only the beginning.

The California income tax allows you *no credit for earned income.* The tax spenders who framed the law provided for depreciation of buildings and equipment; they ignored the fact that your professional skill is a wasting asset, and is so recognized in every other comparable state, as well as by the Federal Government.

You need not be reminded that, by denying the normal credit for dividends, the tax assesses a heavy penalty against any income you are fortunate enough to receive from invested savings. Nor have you failed to note, in making your first payments to the State income tax collector, that the total is distressingly higher than you were led to anticipate.

The Legislature next year, beyond any question of doubt, will increase the tax unless the voters of California take this direct power out of its hands.

Our physicians' Committee of Allied California Citizens asks your moral and financial support in accomplishing that objective. Proposition No. 2 on the State ballot takes from the Legislature the power to directly dip into wages, salaries and personal income from invested savings. It provides that no tax on personal incomes shall be imposed except by a vote of the people. And, finally, it repeals the personal income tax now in effect. You are invited to enlist in the fight to write Proposition No. 2 into the fundamental law of this state.

Funds are urgently needed to carry on the educational campaign in behalf of Proposition No. 2. The committee of your colleagues whose names appear on this letter, urge you to mail a contribution *now* to Allied California Citizens, 308 Sharon Building, San Francisco.

Enlist with more than your financial help. Do your part, in your circle of friends and acquaintances, by informing and arousing public opinion. Urge them to vote "Yes" on Proposition No. 2, November 3.

Physicians Committee, Allied California Citizens:

LEROY H. BRIGGS, M. D., *Chairman*
DONALD J. FRICK, M. D.
HERBERT C. MOFFITT, M. D.
ROBERT A. PEERS, M. D.
CLARENCE G. TOLAND, M. D.
REGINALD KNIGHT SMITH, M. D.

SPECIAL ARTICLES

Health Exhibit:* New York World's Fair of 1939

Plans for a great health center and permanent public museum of health and hygiene for the New York World's Fair of 1939 were announced September 6, with the formation of an advisory group representing city and national health and medical organizations.

In making the announcement, Grover Whalen, president of the Fair Corporation, said that health and medical science will be ranked as one of the most important phases of the Fair. Plans for the necessary buildings and exhibits are yet to be worked out, but both the Oberlander Foundation and the Carnegie Corporation have already pledged financial aid. Other grants are expected to provide a fund for retaining the exhibits as a nucleus for the permanent museum.

The committee, of which Dr. Louis I. Dublin will be chairman, will undertake a fivefold project involving the establishment of a permanent museum of hygiene such as the famous German institution at Dresden.

The five major objectives as announced are:

1. A complete coördinated health and medical exhibit, illustrating for public education the results of medical research, which would furnish during the Fair a nucleus for a large group of commercial exhibits of products related to health and afterward the nucleus of a permanent institution.

2. A model health village constantly demonstrating equipment and methods in daily use by individuals, families, and communities.

3. Emphasis at every appropriate point throughout the Fair of protective devices and services installed for the benefit of the visitors, which illustrate with commercial advantage the value of the device.

4. Provision for a permanent health center.

5. A strict censorship of medical products and other things sold or promoted on a health basis. . . .

Secretary Calver has just returned from abroad, where he spent eight weeks visiting health museums and expositions to seek material for inclusion in the exhibits here. He brought back more than fifty exhibits from Germany, France, and England for consideration of the Fair committee.

The medical center and exhibits are being planned, it was explained by President Whalen, with the aim of presenting "the material, social and professional equipment now available to society for its health protection and promotion, and to provide a dramatic visualization of the brilliant possibilities for a humanity fully served with these facilities.

"Public health and medicine are deeply concerned with the future of individuals and the race. Their objective is aptly phrased by Doctor Dublin in the statement, 'If we could apply the knowledge we possess we could add ten years to the average life expectancy in America.'"

The health and medical exhibits, it was pointed out in Mr. Whalen's statement, will tell simply of the relation of the exhibits to the individual, with man himself as the central motif. In the exhibit, it is planned to have representations of:

"Models of the human embryo in its various stages of development.

"Formation of habits, nutrition and other problems of bodily and mental development in the early years of life, illustrated with common examples which the visitor may recognize from his own experience.

"Protective devices in school and playground, discovery and correction of defects, organization of the school for health and health teaching, posters, models, plays and programs prepared by the children themselves, would visually demonstrate the beginning of participation by the individual himself in his own health protection and promotion.

"Men and women in adult life, their hazards of occupation, personal hygiene, periodic examinations, accident prevention, responsibilities of parenthood, typical problems illustrated here with moving devices, and mechanical demonstrations, will carry along the dramatic story of man's inward struggle to survive and prosper in his modern environment. . . .

"A considerable section of the exhibit will be devoted to the early recognition of degenerative diseases, such as heart disease, cancer, nephritis, and diabetes. The fact that much may be done to prolong the lives of those who suffer from these diseases should alleviate the mental strain and stimulate sufferers to avail themselves of the skill of surgeons, the benefits of x-rays and radium, the relief afforded by insulin, etc.

"Dominating this section of man himself and visually summing up the health story of his life may be a life-size man, woman and child, all transparent (as was the transparent man at the Century of Progress), naturally posed and inwardly illuminated to furnish a brief lesson in gross anatomy and surrounded with working models of the heart, the lungs and other organs, so that the visitor can see 'how the wheels go round' and thus better understand the care of his body.

"Why do some people get sick and some stay well? The question of immunity affects all age groups. A special section of the exhibit may be set aside to deal with this little-understood problem. What we know about immunity, how it may be acquired naturally and artificially, its possibilities and limitations. This story has never been told wholly and understandably to the public. Working models showing the reactions of toxin and antibodies as they are now understood will provide a sympathetic understanding for immunization and vaccination services."

Other subjects to be included are: Air hygiene and ventilation; nutrition and the food supply; water purification and sewage disposal; municipal cleansing; noise—its cause, effect, and prevention; mental hygiene—what it is and how it serves; epidemiology and the disease detective; protein poisoning—the ragweed and its allies; the sagas of the health heroes of history; quacks, quackery, nostrums, fads, and fallacies; superstitions—old and new—relics of the medicine man.

---

* The Golden Gate International Exposition, to be held in San Francisco in 1938, will also present a large health exhibit.

TWENTY-FIVE YEARS AGO[†]

EXCERPTS FROM OUR STATE MEDICAL JOURNAL

Vol. IX, No. 10, October,[*] 1911

From Some Editorial Notes:

Variola and Varicella in San Francisco.—According to a recent publication of the United States Public Health and Marine Hospital Service, smallpox is and has been for the past few years quite prevalent throughout the United States. While the disease is of a mild type, and the mortality with few exceptions low, still it behooves us in California in general, and San Francisco in particular, to be constantly on our guard, and to in every way coöperate with the local and state Boards of Health in their endeavors to eradicate the disease.

During the year 1909 over 24,000 cases were reported in the United States, with a mortality ranging from .10 per cent to .50 per cent in most localities up to as high as 20 per cent in Norfolk, Va., and even higher in a small epidemic in South Carolina. The figures for the State of California are incomplete, but the records of the San Francisco Isolation Hospital show that since 1900 an annual average of 124 cases have been treated, with a mortality of less than one-quarter of one per cent for the past four years. . . .

* * *

The Exceptional Child.—In another part of this JOURNAL we publish the very excellent set of record blanks devised by Doctor Grossmann for investigating the physical and mental potentialities of children. Doctor Grossmann in an address to the San Francisco County Medical Society made evident the great importance of a better understanding of child development, and claimed that 25 per cent of our children depart from the normal. . . .

* * *

Disinfection of the Skin.—In the performance of our ordinary surgical operations the possible sources of contamination are the hands of the surgeon, the materials used (instruments, ligatures and sutures, dressings, etc.) and the skin of the patient. By the employment of reasonable care, rubber gloves, gowns and masks, and the usual methods in vogue for the sterilization of our instruments, ligatures and dressings, the surgeon and his materials are rendered reasonably safe. The skin of the patient alone remains. . . .

From an article on "Abnormal Body Temperatures in Injuries of the Cervical Spinal Cord" by Ray Lyman Wilbur, M.D., San Francisco.

The essential clinical features of the case which gave rise to this paper were a sudden, complete and unvarying paralysis and anesthesia of all parts of the body supplied from below the level of the fourth cervical cord segment, diaphragmatic respiration, absence of the sphincter and all other body and limb reflexes except the plantar, which was at times exaggerated, transient priapism, and high temperature with slow pulse rate, all the result of a fracture dislocation in the cervical region. (See paper of Dr. T. M. Williams, *Journal American Medical Association*, July 22, 1911, p. 283, for full case report.) . . .

From an article on "Treatment of Nevus Vascularis by the Use of Carbon Dioxid Snow" by D. Friedlander, M.D., San Francisco.

Within the last ten years, or, more properly speaking, within the last five years, for it is only within that time that it has been brought into practical use, a new remedial agent has taken a definite place in dermato-

(Continued in Front Advertising Section, Page 14)

[†] This column strives to mirror the work and aims of colleagues who bore the brunt of Association work some twenty-five years ago. It is hoped that such presentation will be of interest to both old and new members.

[*] As stated on page 355 of the September, 1911, issue of the *California State Journal of Medicine*, owing to the illness of its editor, Dr. Philip Mills Jones, the *Journal* was brought out by the Publication Committee.

BOARD OF MEDICAL EXAMINERS OF THE STATE OF CALIFORNIA[†]

By CHARLES B. PINKHAM, M.D.
Secretary-Treasurer

News

The results of the written examination held in San Francisco July 7 to 9, inclusive, show 146 graduates of medical schools passed the examination, together with thirteen chiropodists and three drugless practitioners. The highest mark (90 6/9 per cent) was made by Kenneth H. Abbott, M.D., Ontario, California, a graduate of the College of Medical Evangelists, June 21, 1936.

A total of 116 applicants took the written examination given in Los Angeles July 21 to 23, inclusive. Altogether, 101 physicians and surgeons passed, together with two chiropodists and one midwife. The highest mark (89 per cent) was made by Oscar Weiss, M.D., Los Angeles, California, a graduate of Rush Medical College, Chicago, Illinois, June 15, 1936.

The many years of effort of the California Board of Medical Examiners in the investigation and prosecution of eyesight swindlers gives promise to be brought to a satisfactory termination because of the coöperation of the United States Post Office inspectors. Said the San Francisco *Examiner* of September 18, 1936: "Dealing a smashing blow at what they describe as 'the most vicious band of racketeers in the nation,' postal inspectors tonight had seized thirty fake eye surgeons and wrecked a $5,000,000-a-year bogus medical business. The arrest climaxed an investigation extending over a year. The names of those seized have been withheld by postal officials, pending further arrests within the next week. . . ." An article on the eyesight swindlers, compiled by Secretary Pinkham, was printed in the annual report of the Board of Medical Examiners for 1930. A supplemental pamphlet on this subject was published by Secretary Pinkham in 1933. (See Bulletin of the Federation of Medical Examining Boards, 1933, p. 46.) The secretary of the Texas Board of Medical Examiners has also waged an active warfare against this group of swindlers. Commenting on the activities of the eyesight swindlers, the Santa Rosa *Press-Democrat* of August 9, 1936, in an editorial headed "Their Crime Contemptible," said: "In trading on the credulity and hopes of sufferers from disease in any form, quacks and other deceivers are guilty not only of obtaining money by false pretenses, but of cruelty in one of its worst forms. No mental agony is greater than having the cup of hope dashed from the lips of a person seriously afflicted in body. . . . In this day it is hard to understand how anybody will give a large amount for supposed medical service to any 'practitioner' without knowledge as to his professional standing. Such incidents belong in the category with the criminal activities of organized gangs who pretend to grow gold in flower pots."

Thomas P. Hunter, who passed with a high rating the examination for inspector of the Board of Medical Examiners, recently given by the State Division of Personnel, was on September 1, 1936, appointed inspector for the Board of Medical Examiners for the Northern California District, to succeed Harry G. Henderson.

"Medical and hospital insurance for more than 40,000 California Credit Union members, including 7,500 San Francisco salary and wage-earners, is being planned by the California Credit Union League, it was revealed today by Leo H. Shapiro, attorney, chairman of directors.

Western Electric
ELECTRICAL
STETHOSCOPE

Amazing new instrument amplifies heart sounds . . . Isolates and accentuates murmurs . . . Makes diagnosis of heart conditions easier

Some years ago, the Bell Telephone Laboratories designed the hospital type Electrical Stethoscope — for use in the operating amphitheatre. Now these same Laboratories have developed a *portable* model: The Western Electric 3A.

It has proved a valuable aid in diagnosing heart ailments—being particularly helpful to doctors with impaired hearing —as it amplifies heart sounds up to 100 times the intensity obtained with an ordinary acoustical stethoscope.

Doctors find it invaluable in examining thick-chested patients and in detecting heart conditions in their early stages. The *filter circuit* isolates and accentuates murmurs — often so hard to detect. Price $116.00.

(Continued from Front Advertising Section, Page 30)

Some doctors give it in the third month or even earlier. Green vegetables should be begun by the sixth month. Potatoes (baked) may be begun at the tenth month, but must not take the place of green vegetables. Dry toast or zwieback may be given after the baby's first tooth has come. Stewed fruit—apple sauce or prune pulp—may be begun at the tenth month.

When the baby is seven or eight months old, ask the doctor about weaning him and about what food to give him. Usually it is a mixture of whole milk (pasteurized), water, and sugar, boiled three to five minutes in a saucepan or cooked for twenty minutes in a double boiler. As a rule, weaning should take about three weeks and should be completed by the end of the ninth month.—*The Children's Bureau, United States Department of Labor, Washington.*

Caring for the Baby.—Proper care of the baby means a regular routine of bathing, dressing, feeding, sleeping, sun baths, play and exercise, and elimination. The mother should plan a regular program for the baby, but the program need not be so rigid that it can never be altered. Proper care of the baby also means planning suitable clothing for him and if possible a well-arranged nursery.

For the nursery, a bright, sunny room is best. If the baby cannot have a room to himself, he should at least have a separate bed. A good bed lets the baby lie perfectly flat. At first a large flat clothes basket will do for a bed, but a crib will be needed as soon as the baby tries to sit up.

Babies need sunlight. When the baby is about three or four weeks old he should begin to take sun baths—outdoor sun baths for the spring and the summer baby, indoor sun baths, through an open window, for the late fall and the winter baby. Sunlight and cod-liver oil help to protect the baby against rickets. When the weather permits, the baby should take his nap out of doors.

The normal baby exercises constantly when awake, crying, kicking, tossing his arms about, stretching, and, later,

An X-Ray Power Plant About the Size of Your Hat

—YET SURPRISINGLY EFFICIENT FOR OFFICE AND PORTABLE WORK

WHEN both the high-voltage transformer and x-ray tube are immersed in oil and sealed within the same container, you have a unit which in bulk seems exceedingly small when compared to the amount of x-ray energy it delivers. But that's the result of *complete* oil-immersion, also the reason for its shockproof operation.

Hundreds of physicians have found this G-E Model "F" Office-Portable X-Ray Unit to be just what they had long wanted—a small unit to be set on the desk, ready for service by simply plugging in to the nearest electrical outlet when a simple radiograph or fluoroscopic examination is desired. In the management of fracture cases especially, the location of foreign bodies, or for emergency service in the patient's home, these users find it practically indispensable—a convenience both to themselves and their patients.

It's highly probable that you are skeptical of the ability of such a small x-ray unit to serve a worthwhile purpose. If so, then do as most present users of this unit did—ask us to put it through its paces—right in your own office, and without any obligations.

learning to creep. During the baby's waking hours his position should be changed from time to time. The baby needs regular exercise. Twice a day, before his morning bath, and after undressing him for the night, let him kick and play freely on the bed for a few minutes while he is undressed.

The baby's activities should not be restricted by tight clothing. The baby's clothing should be planned for his comfort. According to the weather and also the temperature of the room, porch, or yard, his clothing may range from a diaper alone to a complete outfit of band with shoulder straps, shirt, stockings, flannel petticoat, dress, coat, and cap.

The baby should have his own towels and wash cloths for his daily bath. The bath may be given at any hour that suits the mother, such as before the midmorning nursing.— *The Children's Bureau, United States Department of Labor, Washington.*

Protecting the Baby Against Disease.—Keeping the baby well involves more than careful attention to his feeding, training, and his regular routine. It means careful adherence to the doctor's advice, and it also means avoidance of disease by protecting the baby against communicable diseases.

A complete examination of the baby will be made at birth by the doctor. At least once a month the mother and baby should be seen by the doctor for general advice. In addition, the mother should take the baby to the doctor for a thorough examination at least four times during the first year—at three months, six months, nine months, and twelve months of age.

When the doctor makes a health examination he will undress the baby completely, weigh him, examine his head, eyes, ears, nose, gums, mouth, teeth, tongue, throat, glands, heart, lungs, abdomen, genitals, back, arms, legs, feet, skin, and posture—if the baby is old enough to stand. He will ask about the baby's food and his habits of eating, sleeping, exercise, and elimination.

When the baby is six months old, or soon after, have the doctor immunize him against diphtheria. Before he is one year old have the doctor vaccinate him to protect him against smallpox.

Keep the baby away from anyone who is ill. A person who has "only a cold" or "just a cough" may infect a baby and make him seriously ill. Never take the baby into crowded places, such as stores or theaters. Avoid baby shows.

Keep flies and other insects away from the baby and from his food.

Boil his milk and drinking water and, unless the doctor orders otherwise, cook all his other food except fruit juices and cod-liver oil.—*The Children's Bureau, United States Department of Labor, Washington.*

Maggot Study Yields New Facts on Urea.—Digging deeper into the recent mystery of how blowfly maggots stimulate healing in stubborn wounds, a fact observed by surgeons during the World War, Dr. William Robinson of the United States Department of Agriculture now announces the possibility that urea, a well-known and widely distributed chemical, may be responsible along with allantoin for this remarkable healing produced by maggots.

Doctor Robinson has been investigating this subject in the Division of Insects Affecting Man and Animals, Bureau of Entomology and Plant Quarantine. He announced last year the discovery of allantoin in maggot excretions. He now finds that urea is present also. Preliminary tests indicate that the pure synthetic chemical by itself induces the same healing as maggots or allantoin. These preliminary observations, of course, must be supplemented by additional clinical tests by competent physicians—and this is outside the scope of the Department's investigations.

In an article appearing in the August number of the *American Journal of Surgery*, Doctor Robinson cites case histories provided by physicians, surgeons, and dentists,

To Promote Physiologic Activity of the Liver

Decholin

(Reg. U. S. Pat. Off.)

Riedel-de Haen, Inc.

Liver function is of exceeding importance in health and disease. . . . Stimulation of physiologic activity of the liver is a specific property of Decholin (dehydrocholic acid), a pure derivative of bile. . . . Decholin is practically nontoxic. Its administration is followed by an increase of 100 to 200% in the amount of bile secreted. It is ordinarily administered in tablet form, but may be injected intravenously, in the form of Decholin-Sodium, when prompt and powerful choleresis is indicated. . . . Write for a sample and literature. The many and varied uses of Decholin are discussed in five booklets — the Decholin Library — sent free to physicians on request.

"Two Generations of Appliance Makers"

(Continued from Preceding Page)

who have used urea solution in the treatment of osteomyelitis, gangrene, old ulcers, stubborn wounds, infected burns, and nonhealing gums and tooth sockets. The reports are encouraging. If borne out by subsequent clinical tests, Doctor Robinson's discovery will be of great importance to the medical profession.

These physicians and many others became interested in the use of urea through a previous interest in allantoin, which in fifteen months has come into extensive manufacture and wide use from the starting point of an obscure and practically unused chemical.

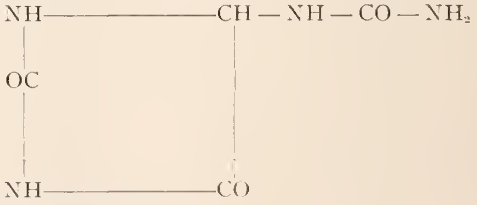
Urea is present in the tissues and blood of animals and humans and is of common occurrence in plants, including many used as food, such, for example, as spinach. However, it got its name from the fact that it was first found in urine, in which form the excess nitrogen is removed from the body. Urea is of great historic interest since it was the first organic chemical ever to be made synthetically. That epoch-making discovery was made more than one hundred years ago.

Urea is an almost snow-like, crystalline chemical, and under the microscope a pinch of it looks like a miniature log jam of sparkling stacks of ice. Chemists now make it by the ton by combining three gases which occur in air or water—nitrogen, hydrogen, and carbon dioxid.

In the treatment of wounds, urea has been used mostly as a two per cent solution, but, unlike allantoin, it is highly soluble and heavy solutions may be made. Pure urea, much used by doctors as a diuretic, sells for only a small fraction of the price of allantoin.

Attention was called to the healing possibilities of urea not only because it was associated with allantoin in maggot excretions, but also because the chemical "picture" of allantoin shows how easily its "side chain" might be "chipped" off by hydrolysis to form urea. It has been suggested that this "chipping" may occur when allantoin is used in wounds, leaving urea as an active agent in healing.

The structural chemical formula or "picture" of allantoin is:



The formula for urea is:

$NH_2 — CO — NH_2$

Treatment of Gonorrhea in Women.—Notes describes the clinical treatment of 2,129 positive cases of gonorrhea of the female genitalia over a period of four years. Positive diagnosis was based on smears with Gram-negative intracellular diplococci having the morphology of the gonococcus combined with objective clinical signs. Extracellular Gram-negative diplococci were considered suggestive. Each patient was observed two months for recurrence of positive smears. The basis of treatment in the beginning was drainage and antisepsis. In 1931 the antiseptics used in treatment included iodin and compound solution of cresol as douches and by topical applications, and of 384 cases admitted four were discharged. In 1932 the antiseptics used included iodin, compound solution of cresol, mercurochrome, and 10 per cent silver nitrate, and of 522 patients admitted eighteen were discharged. In 1933, of 546 cases admitted forty-eight were discharged. In August, 1933, treatment on the bases of creation of local reaction and drainage with the omission of antiseptics was begun as follows: All cervices with cervical glands functioning were cauterized one or more times with the electrocautery at intervals of two or more months in order to cause local reaction and to give better drainage of the active focus. The urethral meatus and the cervix were treated weekly with applicators saturated with 25 per cent solution of

silver nitrate. Five per cent sodium bicarbonate douches were taken by the patient at home twice daily. Nightly instillations of 1 drachm (4 cubic centimeters) of 1 per cent lactic acid jelly were made by nozzle to the vaginal vault in order to promote the normal bacterial flora and to get rid of secondary invaders, which cause desquamative vaginitis. During the first six months of this period, clinical improvement and increase in negative smears were marked. The author concludes that antiseptics should be abandoned in the treatment of gonorrhea in women.—*American Journal of Obstetrics and Gynecology.*

So-Called Ptomain Poisoning.—Goforth says there is no justification for the continued use of the expression ptomain poisoning. Food infection, the invasion and growth in the body of pathogenic microörganisms capable of producing toxins, and food intoxication, a poisoning produced by toxins formed by bacteria in food before ingestion, constitute the largest and most important varieties of acute food poisoning. The organisms of the Salmonella group, particularly Bacillus aertrycke, enteritidis and suipestifer, are responsible for the majority of outbreaks of acute food poisoning. These organisms are capable of forming a heat-resisting irritant, which can produce acute gastro-enteritis. The sources from which the organisms causing bacterial food poisoning are derived are not completely known. Protein foodstuffs, particularly meat and milk products, are the vehicles of infection in the majority of instances. Laboratory methods are necessary in proving the diagnosis and etiologic factors of food poisoning. They should be more frequently employed when the physician makes his initial detailed study of the case. Accurate conclusions presuppose the support of pertinent clinical data. The increasing number of medico-legal cases of food poisoning emphasizes the necessity for the early, complete and accurate collection of data and materials for examination in each case by all associated with the case. The prevention of bacterial food poisoning depends to a large extent on the coördinated activities of the laboratory workers, the public health officer, the veterinarian, the nurse, and the general practitioner. Rigid standards of sanitation regarding the preparation, preservation, handling and exposure of foodstuffs should be maintained. Extended research is needed to bridge the gaps in our knowledge of bacterial food poisoning.—*Southern Medical Journal.*

Medical Progress in the Philippines.—In 1935 there were in the Philippines a total of 2,901 physicians for an estimated population of about 13,500,000. There was, therefore, one physician for every 4,700 inhabitants, or about twenty-one physicians per hundred thousand of the population. This compares with 126.6 physicians per hundred thousand of the population in the continental United States. A review of the past and present medical services in the Philippine Islands has recently appeared under the auspices of the local medical society. Medical services are rendered by the Philippine Government, private practitioners, private corporations, semigovernmental institutions, and the United States Government.

One way of measuring the efficiency of medical services is comparison of the mortality rates. This is a crude method and subject to numerous modifying factors, but it does give information. For many years there has been a steady decline in the mortality rates in the islands. From a rate of 39.7 during the Spanish régime it shot up to 50 from 1899 to 1903 and came down to 27.05 in 1904. Since 1904 there has been a gradual decline, except for 1918, and since 1921 it has been below 20 per thousand. This rate compares with a rate of 14.7 for the United States, 40 for China, and 28 for Spain. It is still higher than the rate of the Anglo-Saxon countries, but, with the exception of Japan, the lowest of the oriental. It is also lower than the rates of Puerto Rico, Spain, and Mexico.

Part of the high death rate has been due to infant mortality, largely infantile beriberi. The effectiveness of the campaign to reduce infant mortality is illustrated by the decrease in the infant death rate from 225 per thousand in 1904 to 140 per thousand in 1933.

DIGITOL

DIGITOL is a uniformly dependable fat-free tincture of digitalis standardized biologically by the one-hour frog method now official in the U. S. P. XI.

The uniformity of Digitol is carefully maintained, from the selection of the digitalis leaf to the finished preparation. Samples of all leaves are subjected to careful analysis to assure proper identification and absence of adulterants, and to make certain of full glucosidal content and physiological activity. Biological standardization of the finished preparation assures the uniformity and dependability of Digitol. The date of biological test is placed on the label.

As a further safeguard, Digitol Mulford is offered only in one-ounce sealed amber bottles supplied with a specially-designed standardized dropper for ease and accuracy in administration.

For Children's Colds

THE ease of application which makes Benzedrine Inhaler so useful with adults is even more important in treating the congestion occurring in children's head colds. The vapor form—in addition to its greater effectiveness — overcomes the strenuous objections which children show to liquid inhalants as applied by drops, tampons or sprays.

Furthermore, the simplicity of Benzedrine Inhaler makes it especially suitable for pediatric use; it has been shown to have no deleterious effect even on the delicate cilia of the nose. Nor is there any oil to be aspirated and become a potential source of later trouble by accumulating in the lungs (Graef: Am. J. of Path., Vol. xi. No. 5, Sept., 1935).

Secondary reactions are "so infrequent and so mild as to be virtually negligible" (Scarano: Med. Record; Dec. 5, 1934), and even in very young children, overstimulation or other undesirable reactions do not occur with the proper dosage.

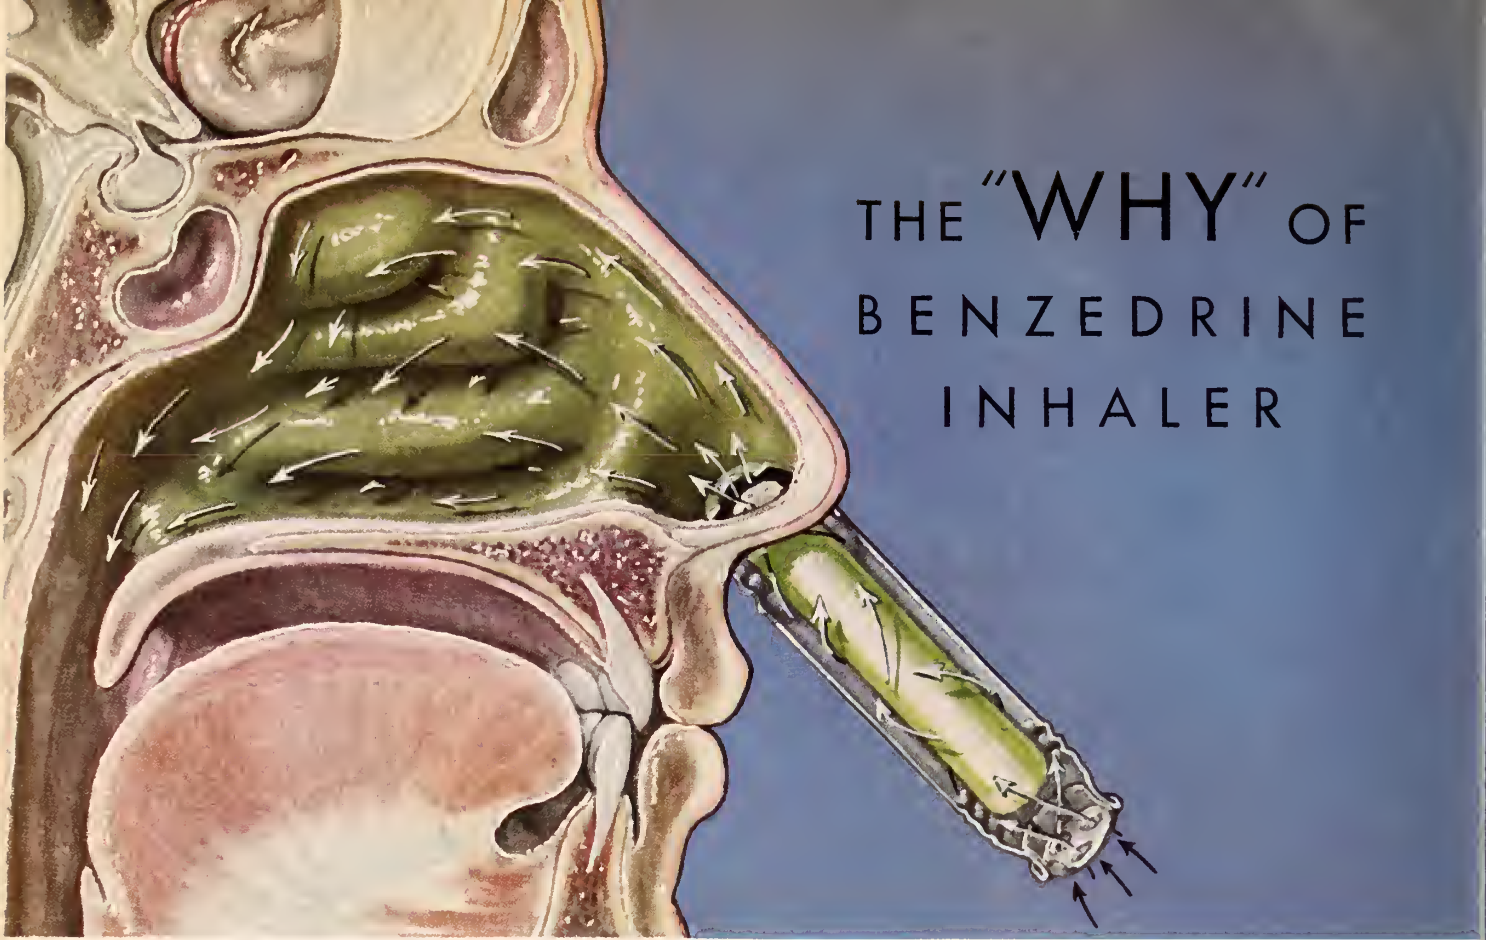
BENZEDRINE INHALER

A Volatile Vasoconstrictor

SMITH, KLINE & FRENCH LABORATORIES, PHILADELPHIA, PA.

EST. SKF 1841



THE "WHY" OF BENZEDRINE INHALER

- The structure of the rhinological tract is so complicated that, when congestion is present, the whole of the affected area cannot easily be reached by a liquid vasoconstrictor.
- On the other hand a volatile vasoconstrictor diffuses throughout the entire nasal cavity. Benzedrine* is a vasoconstrictor combining VOLATILITY with a POTENCY greater than that of ephedrine.
- To present these two properties of Benzedrine in the simplest and most convenient manner, the inhaler form was adopted—an aluminum tube with gas-tight screw caps, containing a cotton roll impregnated with Benzedrine.
- Thus, though the word ''inhaler'' may suggest the outmoded aromatic inhalers of the past, actually this presentation of Benzedrine is logically dictated by the properties of the drug itself.
- And Benzedrine Inhaler—effective, convenient and inexpensive—marks a distinct therapeutic advance in the symptomatic treatment of head colds, sinusitis, vasomotor rhinitis, hay fever and nasal congestion generally.

(Continued from Page 39)

Another important fact brought out by this report is the large share of credit due the private practitioners for the improved conditions. Of the 2,901 medical practitioners in the Philippines only about 745 are in the service of the Philippine Government and about sixty-eight in the service of the United States Government. There has been a considerable increase in the number of medical men in the Philippines, so that the average age of the physicians is relatively low (thirty-eight) and a high percentage are still, therefore, in the prime of life. While this is an advantageous factor, the report clearly shows that there is room for still further increase in the number of physicians and especially for their better distribution. The number of hospitals also has increased from seventy in 1924 to 147 in 1934.

Fernando, who wrote the report, also points out that the remarkable improvement in health attained during the American régime in the Philippines has occurred with a high degree of coöperation between private practitioners and governmental agencies and that neither compulsory health insurance nor complete government practice of medicine has at any time been necessary. There seems to be no question that this improvement will continue, if judged by the constructive recommendations embodied in the report. The time-tested methods of medical progress are clearly shown not to have outworn their usefulness.—*Journal of the American Medical Association.*

Anesthesia.—Sykes points out that it is possible to reduce postoperative mortality below the 4 to 5 per cent average. Certain minimal essentials are required to create a satisfactory service. (1) Resident anesthetists should be appointed at all large hospitals without exception. (2) No person should be appointed as visiting anesthetist without previous experience as resident, thus bringing anesthesia into line with all other branches of medicine and surgery. (3) Anesthetic clerkships should be compulsory for the better instruction of students. (4) It should be an absolute rule that no dresser be allowed to give an anesthetic except under direct supervision. (5) Patients in private wards should invariably get what they pay for—the personal care of an experienced anesthetist. Under no circumstances should the same fee be payable to a senior member of the staff and to a newly qualified house surgeon. (6) The equipment of many hospitals requires a drastic overhauling. Good modern gas machines should always be available. (7) These machines, though robust, are not foolproof. Therefore, no one except people familiar with their construction and mechanism should be allowed to use them or they will never be in working order, nor will satisfactory anesthesia be obtained. Financial considerations in the form of repair bills may thus do what the interests of the patient have failed to do; that is, protect patients against the dangers of unskilled and unsupervised anesthesia. (8) As the science of anesthesia is constantly changing and constantly advancing in common with the rest of medicine and surgery, provision should be made so that suggestions for reforms and improvements may be brought to the notice of the governing body without loss of time.—*British Journal of Anesthesia (Manchester).*

For Acidity and Allied Conditions, we suggest
ADAMS SPRINGS MINERAL WATER

● MANY physicians recommend the water in conjunction with the treatment of stomach, liver and kidney trouble.

ADAMS MINERAL SPRINGS is one of the seven known iron and maganese bi-carbonate springs in the world, and the only one in Western America.

It is not a cure-all, but it overcomes acid excesses in the body, and is a very mild but wonderfully effective eliminator. The bowels function without spasm, the kidney output is greatly increased, and there is *marked* drainage of bile from the gall bladder and liver.

There is also some constitutional upset for a few days, particularly in gall bladder cases. But this is soon over and your patient begins to show improvement and is now in condition to profit by any medication you may prescribe. If the case is an operative one, you have improved your patient and made of him a better risk.

We will be pleased to cooperate in any way whatever, and samples of water are yours for the asking.

No enterprise in the wide range of human experience can rank with training the mind. If, therefore, we have received from heaven nothing so good as the mind, what should be more worthy of exercise and cultivation? No other adventure is to be compared with it. Through it civilization and all man's higher achievements have been won. The report of a gun does not carry so far as the music of the lyre. To pursue intellectual ideals, unlike the privilege of galloping with a king in a royal game park, is a glorious adventure open to every man who cares to live richly and well.—Leon J. Richardson.

Other ways may fail, but one can always tell a second-rate man by the quality of his emotions. The laughter and the tears of a second-rate man are divining rods that no university training, social experience, worldly culture or tailor, can hide.—George Jean Nathan.

I hope that here in America more and more the ideal of the well-trained and vigorous body will be maintained neck and neck with that of the well-trained and vigorous mind, as the two coequal halves of the higher education for men and women alike. The strength of the British Empire lies in the strength of character of the individual Englishman taken all alone by himself. And that strength, I am persuaded, is perennially nourished and kept up by nothing so much as by the national worship, in which all classes meet, of athletic outdoor life and sport.—William James (1890).

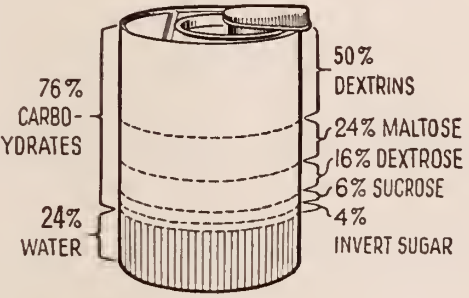
To me it seems as if when God conceived the world, that was poetry; He formed it, and that was sculpture; He varied and colored it, and that was painting; and then, crowning all, He peopled it with living beings, and that was the grand, divine, eternal drama.—Charlotte Cushman.

COMPOSITION
CONCENTRATION
℞
COST

...THE TRIPLE TEST IN PRACTICE!

THE ETERNAL TRIANGLE dominates the lives of products, even as of men. In infant feeding the doctor is concerned with the three factors—*composition*, *concentration* and *cost!* Apply the triple test in your practice. Let us now put it to Karo:

(1) Composition...When you prescribe Karo as the milk-modifier you are providing well-tolerated, readily digested maltose-dextrins-dextrose. The dextrins are non-fermentable; the maltose rapidly transformed to dextrose requiring no digestion; the sucrose added for flavor is digested to monosaccharides. Karo is prepared chemically superior, bacteriologically safe—non-allergic, practically free from protein, fat and ash.



(2) Concentration —When you consider that volume for volume, Karo Syrup furnishes *twice* as many calories as a similar sugar modifier in powdered form, you realize *how* strongly saturated Karo is in calories of maltose-dextrins-dextrose. A tablespoon of Karo Syrup yields 60 calories while a tablespoon of powdered maltose-dextrins-dextrose gives 29 calories. Karo Syrup is a concentrated milk-modifier!

(3) Cost —When you prescribe Karo you help the family out of the economic dilemma. Karo costs $^1/_5$ of the expensive carbohydrates, slashing the high cost of infant feedings. The maltose-dextrins-dextrose of Karo are marketed as a food. The saving is 80%. The Corn Products Refining Company charges for the constituents of Karo and nothing extra for the good name. Apply the triple test to milk-modifiers and you will find Karo desirable in composition, rich in calories, and inexpensive. Karo consists of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor).

Karo Syrup contains twice as many calories as... *Powdered Maltose-Dextrins-Dextrose including Karo Powdered*

Organization of Blood Donors in Germany.—The organization of blood donors is awakening great interest in Germany. The Städtischer Blutspendernachweis, established in the Rudolf Virchow-Krankenhaus in Berlin, has now 128 donors available, five of whom are women. A donor may furnish blood only once a month, and the amount furnished is restricted to 500 cubic centimeters. The compensation for loss of time or earning power by reason of a transfusion is 15 marks ($6). For purposes of general control each donor is provided with a record card, the entries on which correspond with the entries recorded in the filing cabinet at the blood donors' central. The blood donors' central is in a position to furnish within a short time the donor required, previously examined as to blood group.

Since April 1, 1934, Leipzig also has had a blood donors' central, which was created at the instance of Professor Morawitz and is under his direction. During the first year, 106 blood donors were furnished. Applicants were not accepted unless they were free from all signs of infectious disease, presented at least 80 per cent of hemoglobin and 4,500,000 erythrocytes, also a normal number of leukocytes with a normal distribution (no shift to the left and no eosinophilia); their veins had also to be adapted to blood transfusion. As Doctor Seggel of the Medizinische Klinik in Leipzig has emphasized, it was found necessary to make careful inquiries in regard to the moral reputation of applicants, since in a few donors greed predominated over moral principle, while occasionally a donor was found to be morally unsound. It is emphasized that "only donors of pure Aryan ancestry are accepted." As a rule they are either students or members of the national-socialist party. For each hundred cubic centimeters of blood (or fraction thereof) 5 marks ($2) is paid in Leipzig. The Leipzig Krankenkassen do not hesitate to assume these charges. A large percentage of the donors are from the unemployed. In Leipzig the largest amount of blood to be supplied by a donor at one time is ordinarily 400 cubic centimeters; only in an emergency may a larger quantity be taken. As a rule, if more than 400 cubic centimeters is required, two donors must be summoned. In Leipzig also no donor may be used within a month of a previous transfusion. Not only the qualities of the erythrocytes are tested, but also the nature of the blood serum. In Leipzig and in Frankfort-on-Main, donors are reëxamined every three months; in Berlin and in Vienna every two months. When reëxamined the donor must state in writing, on his word of honor, that in the meantime neither he nor any member of his family has been affected with syphilis or other infectious disease. No examination is made immediately before the transfusion; this responsibility, as with the transfusion itself, rests on the physician in charge of the intervention. The Leipziger Krankenhaus, which has undertaken the task of organizing the blood donors, exacts a fee of 5 marks ($2) to cover the general expense. During the first year of the activities of the Leipzig blood donors' central, 420 blood transfusions were performed through its mediation. The group distribution of the 106 donors was as follows: group O, 37.7 per cent; group A, 39.6 per cent; group B, 15.1 per cent; group AB, 7.5 per cent. Of the 420 transfusions, 192, or 45.7 per cent, were performed with blood of group O; 166, or 39.5 per cent, with group A; 50, or 11.9 per cent, with group B, and 12, or 2.9 per cent, with group AB. Each donor supplied blood, on an average, 3.96 times; each donor of group O, 4.8 times, and each donor of the AB group only 1.5 times. The cause for this differentiation does not lie in the fact that frequently unmatched blood was transfused. That occurred in only seven cases (transfusion of O blood to two patients belonging to the A group, two patients of the B group, and three patients of the AB group). The donors of the O group were not examined to discover whether they were "dangerous universal donors" with a high titer of agglutinin in their blood serum. If, for some special reason, a physician desires to transfuse blood to other groups, he

should first convince himself that no danger is associated therewith. In Germany the certification is usually based on uniformity in the grouping of the donor and the recipient. In Paris, however, many universal donors appear to be employed. The total amount of blood involved in the 420 transfusions performed in Leipzig during the first year after the new service was established was 155,000 cubic centimeters. The average amount of blood withdrawn, taking all the transfusions into account, was 370 cubic centimeters. The 420 transfusions were received by 224 patients, 63 per cent of whom received only a single transfusion. The most transfusions (twenty-one) were given in a case of panmyelophthisis; the patient, however, succumbed in spite of a total of 8,430 cubic centimeters of blood injected. Untoward incidents, according to the records in the filing cabinet, occurred in Leipzig in thirty cases (7.14 per cent), although the donors and recipients were properly matched. The accidents were for the most part of a mild nature, ranging from a slight to a more violent chill. In two cases the recipient developed icterus, in one instance on the day of the transfusion and in another case after from eight to ten days. The causes for these manifestations were not explained. No injuries to the donors were observed in any case.

In Thuringia a group of blood donors has been organized by the Schutzstaffeln, a society formed within the ranks of the National-Socialist Party. There are now 214 members of this group available, their residences being widely scattered over Thuringia. The division of the blood groups corresponds to that of Leipzig, which in fact may be taken as the norm for Germany as a whole. But, in contrast with Leipzig, the dangerous universal donors of group O, whose blood has an abnormally high antibody content, are eliminated by application of Coca's method. The donors in Thuringia are free from tuberculosis and syphilis and have no narcotic or alcoholic addiction. Here also blood donor centrals have been created.

Just recently the commander-in-chief of the German army issued regulations concerning the determination of

blood groups in the army. It is being introduced as a routine element of the regular physical examination. For the present, all the soldiers entering military hospitals will be subjected to such a test.

Air Raid Precautions.—The precautions recommended by the British Government against gas poisoning in air raids have been reported in previous letters. Under the title "Rescue Parties and Clearance of Débris" the Air Raids Precautions Department of the Government has issued a memorandum describing the organization recommended for dealing with buildings and roads. It is suggested that this should be attached to the highway department of the local authorities. Whatever area becomes the unit of organization, arrangements should be made with neighboring areas for assistance in case of need. Rescue parties should be organized to release persons trapped in damaged buildings. They should consist of six or eight men, including a skilled foreman. For a densely populated area three or four rescue parties should be provided for every 100,000 of population (two on duty and two in reserve). Apart from their value in time of war, the memorandum adds, persons trained in rescue work might be of value in the case of the collapse of a building in time of peace. Attention is directed to the difficult and dangerous nature of the work, and it is suggested that skilled men should be used in the nucleus of the organization. For training men in the kind of equipment required, assistance could be obtained from such local sources as the fire brigade, mine rescue stations, engineering works, and builders and demolition contractors. Some training in first aid and in the use of gas respirators is also suggested. The occupants of property liable to flooding in the event of an air attack should be warned against taking refuge in basements or ground-floor rooms.

Antigas Instructions. — The Government has issued a circular to all the county and borough councils giving the arrangements for a course of instruction at the civilian antigas school to be established at Failfield, Gloucestershire. The Government will train instructors at the school, who can be obtained by the local authorities for instruction in their localities. The Government will also provide the necessary respirators and protective clothing for local training. The syllabus for the general course will include the principles of civilian antigas precautions, first aid, decontamination and recognition of poison cases. There will also be specialist courses. Each course will as far as possible be composed of persons interested in antigas measures from a common standpoint. Thus separate courses will be provided for instructors primarily concerned in the following duties: (1) police and fire department; (2) first aid, rescue and ambulance work; (3) decontamination of materials; (4) repair of water and gas pipes, cables, and wires that may be contaminated by gas. Two specialist courses, each lasting a week, are contemplated at present. One will be for physicians and nurses and will deal with the medical treatment and care of gas casualties. The other will be for the training of chemists in the detection and identification of gases.—*Foreign Letters, Journal of the American Medical Association.*

Immunization Against Influenza.—At the congress of the Royal Sanitary Institute, Prof. W. C. Topley, who occupies the chair of bacteriology and immunology at the London School of Tropical Medicine and Hygiene, said that two strains of influenza virus were being propagated in ferrets and mice and that before long it would be possible to immunize effectively against the disease. This would be one of the major victories of preventive medicine. He said that vaccination against a virus disease tended to be far more effective than vaccination against a bacterial disease.

There is a principle which is a bar against all information, which is proof against all argument and which cannot fail to keep a man in everlasting ignorance. That principle is "condemnation before investigation."—Herbert Spencer.

The Doctor

Who comes when we are in distress?
The doctor.
Who hears our call and answers: "Yes"?
The doctor.
Who four and twenty hours a day
Is never sure of rest or play
And cannot put his work away?
The doctor.
Who asks no shelter from the rain?
The doctor.
Who braves all storms to comfort pain?
The doctor.
Who in the banquet hall will rise
And all its pleasures sacrifice.
Because somewhere a baby cries?
The doctor.
Who knows no bedtime fixed and sure?
The doctor.
Who all our worries must endure?
The doctor.
Who must his every nerve command
In times of greatest peril, and
Work with a calm and steady hand?
The doctor.
Who to the poor the friend will play?
The doctor.
Who sometimes never gets his pay?
The doctor.
Who, having skill and growing wise,
Must to great profits shut his eyes
And neither boast nor advertise?
The doctor.
Who most deserves man's gratitude?
The doctor.
Who is it prayers should oft include?
The doctor.
Who all through life is standing by,
From birth and that first happy cry
Unto the last, when death is nigh?
The doctor.

—Edgar A. Guest.

He has achieved success who has lived well, laughed often and loved much; who has gained the respect of intelligent men and the love of little children; who has filled his niche and accomplished his task; who has left the world better than he found it, whether by an improved poppy, a perfect poem or a rescued soul; who has never lacked appreciation of earth's beauty or failed to express it; who has looked for the best in others and given the best he had; whose memory is a benediction.—Mrs. A. J. Stanley.

The most important quality of education is flexibility. Flexibility is allied to play. Play is the essence of adaptability, and there is no prescribed pattern for it. Opportunities must be used as they come along.—Boyd H. Bode (1932).

Do not spend your days waiting for an angel to deliver realized hopes at your door. Go out and toil for them. There are few forms of hard work more wearying than waiting.

Better keep yourself clean and bright; you are the window through which you must see the world.—G. Bernard Shaw.

It is better for a man to maintain himself in good health than to load himself with learning.—Arnold Bennett (1920).

Not All the Spellbinders Speak From a Platform

When a speaker mounts the rostrum, you expect exhortations, admonishments and free advice. But, not all of this kind of verbal bombast comes from the platform.

There is another type of spellbinder. He speaks before small, but select, audiences — on the street car, over the bridge table, or, in fact, before any of his friends who will listen.

He's the fellow who knows everything about anything; and he's not averse to telling all who will listen what they should eat, or not eat; what will cure this or that; and why the doctor's advice is all wrong.

Against such "electioneering" only the consistent education of the public to seek proper advice from those properly in authority can undo the wrongs he creates.

Golden State Company feels it is worth mentioning, at least, that it has no misgiven notions about speaking or publishing medical advice. It is our business to produce and distribute the highest quality, safest, most nourishing of dairy products. We believe we do this job well. For the remainder, we advise — "Ask your doctor."

Upon many instances it has been our privilege to offer our technical advice, our research laboratories and our practical knowledge of the dairy industry, to the members of the medical profession to assist in the solution of their problems. The same aid is open to you. You are invited to investigate it.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.

2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.

3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.

4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.

5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

Colfax, California

Just a year ago Lederle introduced—

GLOBULIN *Lederle* MODIFIED

ANTITOXINS

It has been a year of appraisement and ever-increasing usage.

The Globulin-Modified *Lederle* technique, embodying the principle of peptic digestion, is the only practical procedure which permits such a high degree of concentration of antitoxin and reduction in the amount of troublesome proteins—the cause of serum reactions.

That is why Globulin Modified Antitoxins *Lederle* represent

- *a reduction in the expected incidence and severity of serum disease;*
- *less inconvenience to the patient;*
- *a greater ease of administration;*
- *a greater potency per cc.*

At one of the outstanding hospitals 250 patients treated with a Globulin Modified Antitoxin showed a serum disease rate of less than 5%—all indicating a delayed type of serum reaction.

LEDERLE LABORATORIES, INC.
30 ROCKEFELLER PLAZA NEW YORK, N. Y.

San Francisco: 450 Sutter Street Los Angeles: 337 Central Ave.
Lederle Laboratories Depot, Portland: 1216 S. W. Stark Street

Comparison of Lederle's old antitoxins with the new Globulin Lederle Modified —Diphtheria, Tetanus, Scarlet Fever, Erysipelas.

Globulin Modified Antitoxins Lederle are now available also for Gas Gangrene and Tetanus Gas Gangrene.

½ or 1 c. c.? — DIPHTHERIA TOXOID
Alum Precipitated

Reactions which first followed the use of Diphtheria Toxoid (Alum Precipitated) were thought possibly due to the use of the ½ c. c. dose. As there is little if any added discomfort to the one c. c. dose Cutter's half c. c. dose was removed from the market and replaced by a full one c. c. dose. The fact that such reactions are now practically nil following the use of Cutter's Alum Precipitated Toxoid indicate the advantage of the larger dose.

There is no question of concentration as the size of the dose is determined simply by the amount of diluent added. The greater volume properly dilutes the alum with lessened chance for reaction.

What Every Woman Does Not Know—How to Give Cod-Liver Oil.—Some authorities recommend that cod-liver oil be given in the morning and at bedtime when the stomach is empty, while others prefer to give it after meals in order not to retard gastric secretion. If the mother will place the very young baby on her lap and hold the child's mouth open by gently pressing the cheeks together between her thumb and fingers while she administers the oil, all of it will be taken. The infant soon becomes accustomed to taking the oil without having its mouth held open. It is most important that the mother administer the oil in a matter-of-fact manner, without apology or expression of sympathy.

If given cold, cod-liver oil has little taste. On account of its higher potency in vitamins A and D, Mead's Cod-Liver Oil Fortified With Percomorph Liver Oil may be given in one-third the ordinary cod-liver oil dosage, and is particularly desirable in cases of fat intolerance.

AVAILABLE THROUGH ALL PHARMACIES

EMMENIN

The orally active, oestrogenic placental extract elaborated by Dr. J. B. Collip, Department of Biochemistry, McGill University.
(Canadian Medical Association Journal, February, 1930.)

IMPORTANT ANNOUNCEMENT . . .

By an improved technique developed in our laboratories, we have been able to render Emmenin entirely free from disagreeable taste and odor. This has been accomplished without loss of therapeutic activity, and the potency is ensured by carefully controlled biological assay.

DETAILS ON REQUEST

Emmenin is biologically assayed and standardized under direct control of the Department of Biochemistry, McGill University.

Manufactured by
Ayerst, McKenna & Harrison
(United States) Limited
Biological and Pharmaceutical Chemists
ROUSES POINT NEW YORK

Available in liquid form in original 4-ounce bottles.

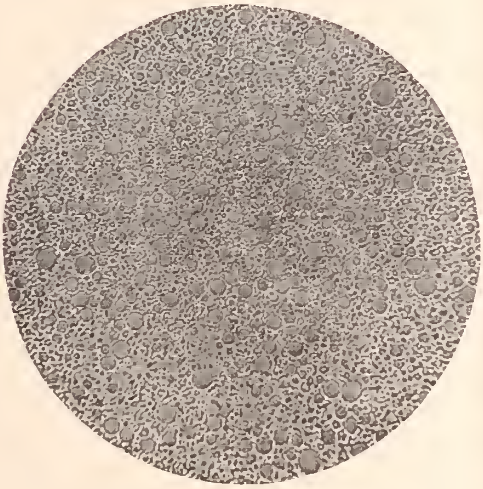
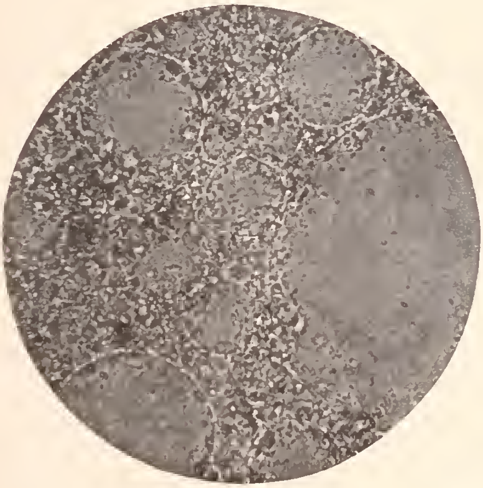
Emulsification AIDS *Utilization*



Microphotograph of Maltine with Cod Liver Oil,★ *enlarged 400 times.*



Microphotograph of another typical malt and cod liver oil compound, enlarged 400 times.

It is commonly believed that emulsification affects utilization. The minute emulsification of Maltine and cod liver oil, made possible by the exclusive Maltine process, is believed to be largely responsible for the thorough utilization of food values contained in Maltine with Cod Liver Oil. In fact, laboratory tests on animals indicate that the vitamin A value of cod liver oil is enhanced *twofold* when emulsified in Maltine, as in Maltine with Cod Liver Oil. A microscopic study of Maltine with Cod Liver Oil reveals exceptionally small globules of uniform size and distribution, whereas the same study of other widely marketed products shows bulky globules of uneven size and distribution.

Maltine with Cod Liver Oil is guaranteed to contain vitamins A, B, D and G. It does not contain molasses or added syrups. It has been esteemed and prescribed by the medical profession for 61 years. The Maltine Co., 60 Hudson St., New York City.

DIPHTHERIA ANTITOXIN, Mulford

PURIFIED GLOBULIN

THE Mulford Biological Laboratories of Sharp & Dohme produced the first commercial diphtheria antitoxin in the United States in 1894. Patient and painstaking research has since evolved constant refinements in product and package. The culmination of this progressive development is Mulford Diphtheria Antitoxin, Purified Globulin—a superior product of high unit value and concentration.

The desirability and advantages of high unit value in small volume have been constantly stressed by medical authorities who urge the use of such an antitoxin earlier in the disease and in larger unit dosage.

Mulford Diphtheria Antitoxin, Purified Globulin, is well adapted for the administration of large unit dosage. Because of the reduction in bulk it is easy to administer and causes less pain to the patient. It is rapidly absorbed and develops quicker patient response due to more rapid neutralization of the toxin. Although highly concentrated, it is isotonic with the blood. It is low in protein.

* * *

To meet the physician's requirements for passive immunization of his patients or for administration of large unit dosage in severe cases, Mulford Diphtheria Antitoxin, Purified Globulin, is supplied in a variety of syringes, ready for instant use, in packages of 1,000 units, 5,000 units, 10,000 units, 20,000 units and 40,000 units.

CO-OPERATE WITH YOUR ADVERTISERS

CALIFORNIA AND WESTERN MEDICINE, the official publication of your Association, is made possible in part by reason of the coöperation of business firms and institutions who use advertising space. Their purpose is to direct attention to their products and services to present and future patrons.

Members and readers are urged to give preference to and to patronize these advertisers. When ordering goods, mention CALIFORNIA AND WESTERN MEDICINE.

This coöperation will please the advertiser, increase advertising income, and enable your Association to increase the value of this JOURNAL to members and readers.

A SERVICE AGENCY—FOR READERS

THE JOURNAL of the California State Medical Association and the Coöperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital, or we will refer your request to the proper department of the A. M. A. for reply.

We invite and urge you to use this Service. It is absolutely *free* to every member of the California and Nevada Associations. The Coöperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in CALIFORNIA AND WESTERN MEDICINE, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This A. M. A. Service Bureau will give you the information. Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to write direct to the Coöperative Medical Advertising Bureau, 535 N. Dearborn Street, Chicago, Illinois. CALIFORNIA AND WESTERN MEDICINE and the A. M. A. Service Bureau desire to serve *you*.

THE CONTINUOUS COURSE IN

OPERATIVE SURGERY

Will Start January 5, 1937

DESIGNED FOR PHYSICIANS IN SAN FRANCISCO AND VICINITY

SUBJECTS INCLUDED:

Stomach and duodenum. Colon and rectum. Gall-bladder and bile ducts. Small intestines.

METHOD OF STUDY:

All of the above topics will be considered in the same manner. The descriptive and surgical anatomy of the organ in question will first be gone over, in the form of lectures, demonstrations on the cadavers, and dissections by the students themselves. The pathology, diagnosis and treatment of each subject will then be briefly considered, and particular attention given to the latest and most approved methods. The principal operations will be described by the instructor and performed by the students themselves on cadavers and fresh human material. Only the best and most up-to-date technique will be included and the students will be required to practice the work until they have not only mastered the subject but have developed the proper amount of skill and speed.

TIME REQUIRED AND FEE:

The work will be given every Tuesday from 11 a.m. to 2:30 p.m. Those desiring to spend additional time may do so without extra charge. Students taking the course will have the privilege of witnessing operations, with demonstrations, on the living at various times during the week. The fee will be $15 per month.

Applicants must be graduates of schools approved by the State Board of Medical Examiners

For descriptive circular and further information inquire of

YOUNG PHYSICIAN DESIRES ASSOCIATION WITH private physician or group clinic. One year postgraduate training Dermatology and Syphilology large university clinic. Graduate Rush. Diplomate National Board. California license. Married. Two rotating internships. Will accept position in Internal Medicine, Dermatology, or General Practice. Address, Box 1100, California and Western Medicine, 450 Sutter Street, San Francisco.

Von Helmholtz, the great German physicist-physician, who, following his education as a surgeon for the army, devoted his active life to physics as related to biologic processes (the ophthalmoscope was his invention), never forgot that he was a physician. "Medicine," he said with pride, "was once the intellectual home in which I grew up; and ever the emigrant best understands and is best understood by his native land."

When you enter the laboratory, put off your imagination as you would your coat. When you leave your laboratory, put it on again. Let your imagination wrap you around before the experiment and between whiles; put it away during the working hours, however, lest it hinder your power of observation.—Claude Bernard.

NUTRI-AD
ARTHROPHYLL
(6)

A Nutritional Adjuvant

IN a wide variety of cases involving Arthritis Deformans also Arthritic and Rheumatic disorders due to calcium deposition NUTRI-AD Arthrophyll (6) has accomplished favorable results to a degree heretofore unreported.

By making available prolific sources of organic phosphorus in a highly assimilable state it is apparent that this natural agency for increased calcium excretion has been provided. » » » » » » »

This procedure together with inducing normal bowel elimination offers a likely solution to this stubborn and widely prevalent pathology. » » » » » » »

NUTRI-AD—ARTHROPHYLL (6) consists of the concentrates of green leafy vegetables so compounded and proportioned as to supply a maximum of phosphorus and a minimum of calcium through which the offending calcium deposits are disintegrated and excreted.

NUTRI-AD—ARTHROPHYLL (6) is available only in prescription form through the ethical medical profession. Literature gladly furnished on request.

IT IS our privilege to present, as our contribution to public health education in America, the Camp Transparent Woman. She is the only one in the world. Life-size, the figure is an exact reproduction of the female body. The outer skin is cellhorn—a substance so transparent that every organ, blood-vessel and bone can be seen clearly through it. An ingenious lighting system illuminates the organs in visible life colors.

We gave this exhibit its appropriate premiere at a private showing to leading health officials, scientists and medical authorities at the New York Museum of Science and Industry. The figure is now being shown to the general public at the Museum before going on a transcontinental tour.

The Camp Transparent Woman is presented to the American public in the earnest hope that it will assist in combating indifference; that it will increase woman's knowledge of her physical self and help to produce a more enlightened attitude toward the advice of the physician.

New Audiometer

MODEL 6A

The generally acknowledged standard for audiometric measurements—supersedes Model 2A—now incorporates the following improvements:

- Employs a heterodyne oscillator so that it can be set for *any frequency* up to 10,000 cycles per second.
- Improved facilities for both air and bone conduction measurements.
- No batteries required—operates on either alternating or direct current.
- Reduced size and weight—more elegantly finished.
- Unique masking attachment for testing bone conduction.
- Additional equipment may be furnished designed to measure the amplification necessary for a patient to obtain speech intelligibility. Indispensable in prescribing hearing aids.

Control of Type I and Type II Pneumonias with

ANTIPNEUMOCOCCIC SERA

Lederle

Success in the serum treatment of lobar pneumonias is measured by . . .

- a 60% reduction in the death rate of Type I cases
- a 40% reduction in the death rate of Type II cases
  (*if injected within 96 hours of onset*)

Specific antipneumococcic sera offer the only certain means of reducing the death rate in Types I and II pneumococcus pneumonias — the cause of nearly 50% of all adult lobar pneumonias between the ages of five and fifty.

> "The Massachusetts Pneumonia Study, under the auspices of the State Department of Health, has demonstrated that specific treatment can be successfully used by physicians in general practice. Over nine hundred patients with lobar pneumonia have been treated by nearly four hundred physicians."*

Success is largely dependent upon prompt bacteriological diagnosis facilitated by the Neufeld Rapid Typing; early and adequate treatment; and of equal importance—the use of serum of the highest quality.

Refined and Concentrated Antipneumococcic Serum *Lederle* represents the accrued knowledge gained by years of experience in its manufacture.

* "Lobar Pneumonia and Serum Therapy" by Frederick T. Lord and Roderick Heffron, published by The Commonwealth Fund in 1936.

As the Nation Moves Forward

» It is certainly no news that America has been passing through a depression.

» The James H. Barry Company, like every other business in the land, has had its problems during this trying period. And like every other enterprising American business, this company has faced those problems with honesty, patience, and resourcefulness. But most of all, with determination to GO AHEAD.

» A vast range and variety of betterments in printing technique and equipment is the result. We have not waited for the dawn of business revival to make these improvements. In the past depression years thousands of dollars have been spent annually by us, keeping pace with the many changes in our particular industry.

» Yet today, this company is embarked upon the most ambitious expansion program in its history. On November 1, we occupied our own building—especially designed and engineered to suit the needs of our exacting manufacturing requirements—comprising more than 22,000 square feet, on Van Ness Avenue South near Thirteenth Street. Moreover, additional high speed printing and binding equipment has been installed.

» Perhaps it takes courage to make these huge investments. Rather, we believe, it takes FAITH. Faith in America, in our community, and in our own ability as craftsmen to give the buyers of printed matter an honest dollar's worth.

Fundamental Research

From an Address by Dr. G. H. A. Clowes, Director, Lilly Research Laboratories

"Courage is required on the part of a commercial organization to engage in research without any prospect of immediate financial return, but unless this course is followed we may rest assured that the flow of scientific discoveries which have proved so beneficial to mankind in the last three or four decades will ultimately cease."

* * *

By fostering fundamental investigation the Lilly Research Laboratories endeavor to contribute to the advancement of medical knowledge. In addition, the Lilly Research Laboratories co-operate with other workers, in developing important medical discoveries.

BOOK REVIEWS

Brain Reflexes and Laws of Existence. By W. D. Hoffman, M. D., Los Angeles. Pp. 308. Los Angeles: Parkman Press. Price $10.

The author assumes without warrant that cultists are making inroads in medical practice by suggestive therapeutic methods. That this is so because physicians do not know the principle of the mechanics of the brain and nervous-tissue activity. Hence this text. This premise is not warranted.

However, the author has, from his experience, written in a pleasing way on psychology, psychotherapy, and psycho-analysis. One may broaden his views, gain new insights and be aided in better understanding of patients by studying this text.

Modern Treatment of the Respiratory System. By A. Lisle Punch M. D., England, and F. A. Knott, M. D., University of London. Pp. 295. P. Blakiston's Son and Company, Inc. Price, $5.

The personal views and experiences of the authors are presented on respiratory disease and infection. Numerous x-ray illustrations amplify the text. An English viewpoint is well imparted and consistent with accepted practices.

Oral Diagnosis and Treatment Planning. By Kurt H. Thoma, D. M. D., and Charles A. Brackett, Professor of Oral Pathology in Harvard University; Oral Surgeon to the Brooks Hospital; Consulting Oral Surgeon to the New England Baptist Hospital; Consulting Oral Surgeon to the Tumor Clinic of Beth Israel Hospital. Pp. 379, with 533 illustrations, 71 of them in colors. Philadelphia and London: W. B. Saunders Company. 1936. Cloth, $6 net.

This is a much needed text. It will enable every practitioner to become more capable in interpreting what he sees while examining a mouth. This volume covers the diseases and abnormal conditions of the teeth, jaws and other organs and tissues of the mouth. Primary and sec-

(Continued on Next Page)

A Modern Product

Of Proved Value in . . . the Endotoxic Infections

Edwenil, the polyvalent antibacterial agent, while comparatively new, has already been used so extensively that it has won the place of a leader in the treatment of the endotoxic infections such as the respiratory diseases, boils, measles, etc.

It is a stable, colloidal, protein-free (by the Biuret Test) solution for intramuscular injection.

Edwenil promptly raises resistance to the endotoxic infections but causes no detrimental reactions, either local or general. It can be used daily to advantage. Send for complete literature on

Not all nitrous oxide is of the same purity

Hi-Pure Nitrous Oxide is over 99% pure. Ordinary nitrous oxide has to be only 95% pure by volume to meet the new U.S.P. specifications effective June 1, 1936.

So far as we know, this company is the only one in the United States marketing nitrous oxide over 99% pure.

The presence of nitrogen in nitrous oxide reduces the potency of the gas and narrows the already fine margin between anesthesia and asphyxia.

A higher percentage of oxygen may be used with pure nitrous oxide.

Longer nitrous oxide anesthesia can be obtained with a cylinder of Hi-Pure than with a cylinder of ordinary nitrous oxide.

Using the CO_2 absorption technique, the cost of Stuart Hi-Pure with oxygen is approximately 15 cents an hour.

May we mail you our booklet giving clinical data? Address 211 Bay Street, San Francisco.

ondary manifestations that are symptoms of other conditions are presented in an instructive manner. Methods of examination are described.

Research in Dementia Praecox. By Nolan D. C. Lewis, M. D. Pp. 320. Committee on National Mental Hygiene, New York City. Price, $1.50.

This book is intended to stimulate interest in dementia praecox research, and is sponsored by the Masonic Order. The text presents what is being done in the research field.

The Legal Aspects of Milk Control. By James A. Tobey, Dr. P. H. International Association of Milk Dealers, Chicago.

A reference manual on court decisions on legal aspects of the control of milk.

TWENTY-FIVE YEARS AGO

(Continued from Text Page 448)

success, and there are but few men who can afford to have these failures. On the other hand, at times there will be success when nothing else in the world has been of value. For example, I had a case in one of the London hospitals of the most pronounced tetany. . . .

Dr. Victor Vecki, San Francisco: I have tried hypnotism a number of times, but I have never succeeded in hypnotizing anybody. About thirty years ago I witnessed Urbantschich of Vienna hypnotize several hysterical subjects whom he had brought to a meeting of the Polyclinic, and I have seen the former assistant of Bamberger in Vienna, Doctor Kanders, hypnotize many subjects. I have tried to do this very often. I have bought all kinds of apparatus, things that whirl around before the eyes of the patient, but I never succeeded. . . .

From an article on "Case of Acute Mercurial Poisoning Followed by General Necrosis of Maxillary Bones, and Purulent Otitis Media" by M. Herzstein, M.D., and A. B. Baer, M.D.

On December 3 Mrs. E., 28 years of age, drank a solution containing six 7½-grain HgC. tablets. She vomited freely within five minutes and had her stomach washed at the end of thirty minutes and in the interim drank the whites of half a dozen eggs and two glasses of sweet oil. At the end of an hour she became unconscious and was removed to the hospital. Urine voided by catheter for first time at the end of sixty-two hours. Unable to take nourishment except by rectum, as everything taken by mouth was immediately expelled by vomiting. . . .

California Academy of Medicine.—The regular monthly meeting of the California Academy of Medicine was held in the library of the San Francisco County Medical Society on Monday evening, September 25, 1911, President Ebright in the chair. . . .

The ancient belief that both disease and cure were of divine origin, and the fact that the healing art was practiced to a large degree by the priesthood, have left a permanent stamp upon medical terminology. So the word "plague," according to derivation, means "blow" or "stroke" and implies that the epidemic is an expression of the wrath of angered gods.—Mack.

●

VITAMINS IN CANNED FOODS

V. VITAMIN G

● By 1926, it was apparent that the antineuritic vitamin B of earlier investigators was in reality a combination of several vitamins. In that year, Goldberger postulated the existence of a second vitamin associated with the so-called vitamin B "complex" which he designated as the P-P or pellagra-preventive factor. Evidence has been offered that this factor—subsequently named vitamin G—exerts a specific action in the cure and prevention of human pellagra and a similar condition in experimental animals (1).

Since Goldberger's pronouncement, considerable research has been devoted to resolution of the vitamin B complex and, what is equally important, to testing the specificity of vitamin G in the cure of human pellagra (2).

The findings in the laboratory and clinic have not, in some respects, been entirely in accord (3).

As reports of further investigations appeared in the literature, it became clear that the vitamin B complex had been aptly named. At one time claims were made for the existence of as many as eight factors in this complex (4).

While later work has reduced this number, we know today that what has been considered in the past as vitamin G is, in reality, a combination of several factors. A relation between experimental cataract and vitamin G has been described and, recently, another associated factor was postulated (5).

The significance of these individual factors in human nutrition has not as yet been established. However, regardless of this fact, students of nutrition are agreed that we must provide for the inclusion of so-called vitamin G—admittedly a complex—in the daily dietary. It is also obvious that until more is known about the individual components of the complex, we must continue to depend upon present day bioassay methods to determine the "vitamin G" potencies of foods.

In this connection, many canned foods have been found by comparative studies to retain their original vitamin G potencies as measured by methods now in common use (6).

Investigators in the U. S. Public Health Service have described their values in the control of human pellagra (7).

Commercially canned foods, therefore, may be used with confidence that they will supply amounts of vitamin G consistent with the amounts present in the raw food materials.

This is the eighteenth in a series of monthly articles, which will summarize, for your convenience, the conclusions about canned foods which authorities in nutritional research have reached. We want to make this series valuable to you, and so we ask your help. Will you tell us on a post card addressed to the American Can Company, New York, N. Y., what phases of canned foods knowledge are of greatest interest to you? Your suggestions will determine the subject matter of future articles.

The Seal of Acceptance denotes that the statements in this advertisement are acceptable to the Council on Foods of the American Medical Association.

Allies

in the conquest of syphilis

ARSPHENAMINE
SQUIBB
IODOBISMITOL
SALIGENIN
SQUIBB & SONS
NEW YORK

MOST AUTHORITIES on the subject of syphilis agree that maximum curative effects are obtained when an arsenical and a heavy metal are used alternately and continuously for a period of from at least twelve to eighteen months.

Two products by the House of Squibb—Iodobismitol with Saligenin and Neoarsphenamine—are effective allies in the treatment of syphilis. Neoarsphenamine Squibb is characterized by its rapid and ready solubility, high spirocheticidal power and low toxicity. Also available under the Squibb label, and equally effective when conditions indicate their use, are Arsphenamine and Sulpharsphenamine.

Iodobismitol with Saligenin is offered as a product suitable for obtaining all of the systemic effects of bismuth in the treatment of syphilis. It presents bismuth largely in anionic (electronegative) form. It is slowly and completely absorbed and slowly excreted, thus providing a relatively prolonged bismuth effect. Repeated injections are well tolerated and very effective in both early and late syphilis.

Iodobismitol with Saligenin is a propylene glycol solution containing 6 per cent sodium iodobismuthite, 12 per cent sodium iodide and 4 per cent saligenin (a local anesthetic).

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

Even if
Each Mother had a Kitchen Like This

Model Kitchen Photo Courtesy of The International Nickel Co., Inc.

SHE COULDN'T MAKE A MODIFICATION LIKE S. M. A.

Laboratory equipment and control are necessary to modify cows' milk to approximate human breast milk in chemical and physical characteristics. Kitchen equipment is not intended for work of such precision.

THIS IS BUT ONE OF OVER 50 TESTS PERFORMED ON S. M. A. WHICH ARE IMPOSSIBLE IN THE HOME.

In the S.M.A. plant, tuberculin-tested cows' milk is processed in the finest equipment that money can buy, under the supervision of trained chemists. There the difficult and tedious part of modification to breast milk standards* is done. Therefore, in S. M. A. we are able to offer the physician a product simple to prescribe, the mother a product simple to prepare. Do you wish samples, doctor?

*S.M.A. is a food for infants—derived from tuberculin tested cows' milk, the fat of which is replaced by animal and vegetable fats including biologically tested cod liver oil; with the addition of milk sugar and potassium chloride; altogether forming an antirachitic food. When diluted according to directions, *it is essentially similar to human milk* in percentages of protein, fat, carbohydrates and ash, in chemical constants of the fat and in physical properties.

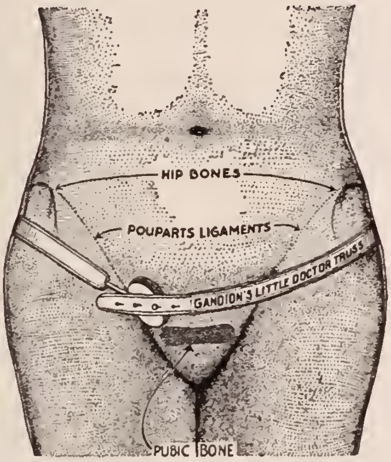
FOR THE

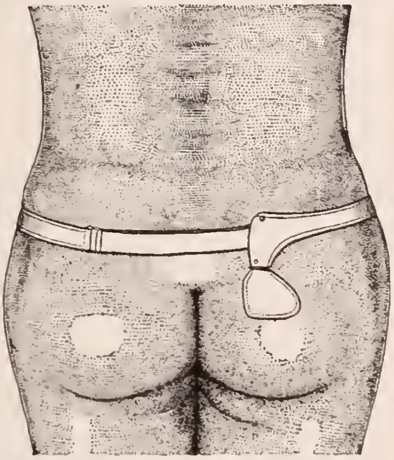
INJECTION TREATMENT OF HERNIA

Use GANDION'S TRUSS



CUT VIII

Gandion's System of Hernia Control has been especially adapted to the Injection Treatment in collaboration with San Francisco's most successful clinics, and has been generally accepted as the standard.



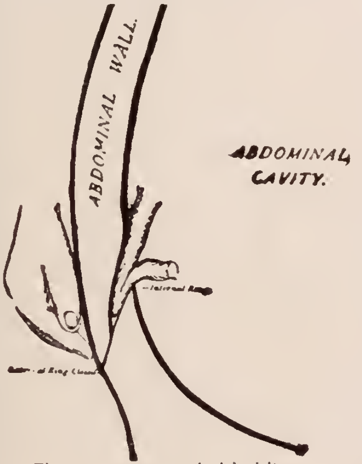
CUT VII

THE GANDION TRUSS has a semi-rigid frame with single strap and low posterior counter pressure. During proliferation a correctly shaped pad firmly holds the tissues in contact over the entire length of the inguinal canal. Truss stays in place and can be easily opened for treatment.

ALSO

Since 1903 we have been the exclusive authorized western distributors for the

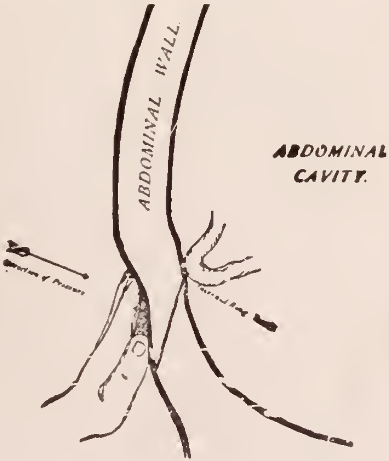
SMITHSONIAN TRUSS HONEST JOHN TRUSS



The wrong way to hold oblique inguinal hernia.

Our representative will gladly call on interested local doctors with further explanation. Out of town doctors please write. Very likely we have a dealer in your city who has been trained in this work and who carries a complete stock suitable for the various types of cases.

Ask for our new catalog of orthopedic braces, belts, elastic wear and other appliances.



The correct way to hold oblique inguinal hernia.

LIVERMORE SANITARIUM

The Hydropathic Department devoted to the treatment of general diseases excluding surgical and acute infectious cases. Special attention given functional and organic nervous diseases. A well equipped clinical laboratory and modern X-ray Department are in use for diagnosis.

The Cottage Department (for mental patients) has its own facilities for hydropathic and other treatments. It consists of small cottages with homelike surroundings, permitting the segregation of patients in accordance with the type of psychosis. Also bungalows for individual patients, offering the highest class of accommodation with privacy and comfort.

GENERAL FEATURES

1. Climatic advantages not excelled in United States. Beautiful grounds and attractive surrounding country.
2. Indoor and outdoor gymnastics under the charge of an athletic director. An excellent Occupational Department.
3. A resident medical staff. A large and well trained nursing staff so that each patient is given careful individual attention.

How Much Sun Does the Infant Really Get?

Not very much: (1) When the baby is bundled to protect against weather or (2) when shaded to protect against glare or (3) when the sun does not shine for days at a time. Oleum Percomorphum offers protection against rickets 365¼ days in the year, in measurable potency and in controllable dosage. *Use the sun, too.*

Oleum Percomorphum Price Substantially Reduced, Sept. 1, 1936!

We are hopeful that by the medical profession's continued whole-hearted acceptance of Oleum Percomorphum, liquid and capsules (also Mead's Cod Liver Oil Fortified With Percomorph Liver Oil), it will be possible for us to make the patient's "vitamin nickel" (A and D) stretch still further.

BOARD OF MEDICAL EXAMINERS

(Continued from Text Page 448)

that the parchment was the license of a reputable Seattle physician, whose name was withheld from the trial record by the prosecution. De Gaston testified he posed as this doctor. In San Francisco, when he operated for the ring there, the license of a San Francisco surgeon was on the wall of his office, De Gaston testified. How the licenses were obtained for De Gaston was not disclosed. De Gaston also testified that questionnaires were given to women patients to be filled out with their names, addresses, telephone numbers, and other information. As De Gaston testified, the actor was watched closely by two of the defendants, R. L. Rankin, former tax expert and asserted 'business brains' of the Syndicate, and by William Byrne, former inspector for State Medical Board in Los Angeles. . . . Rankin and Byrne were in court under guard, having been placed in custody and ordered held in jail by Judge Crum yesterday for the duration of the trial. . . ." (Los Angeles *Herald-Express,* October 9, 1936.)

" . . . In his closing testimony De Gaston said that R. L. Rankin, one of the defendants, told him while he was practicing in Seattle that he should get in touch with the Medical Board investigator there and arrange to pay him off indirectly by making him a stockholder in the Medical Acceptance Corporation." (Los Angeles *Times,* October 10, 1936.)

" . . . De Gaston said another defendant, William Byrne, former California Board investigator, came to Seattle and failed in an attempt to get Harry Huse, State Director of Medical Licenses in Washington, to join the asserted ring. Although not licensed as a physician, De Gaston testified that he opened branches of the alleged ring in Seattle and San Francisco, using licenses given him by Rankin, made out in the name of 'Dr. Lee' and 'Dr. Hoch.' He said he received $750 a month." (Los Angeles *Illustrated Daily News,* October 10, 1936.)

SMOKING AGAINST DOCTORS' ORDERS!

IT is easy to tell a patient to stop smoking, but it is often difficult to make him follow the advice.

We do not advocate smoking against doctors' orders, but we do say that if your patient *insists* on smoking, he should smoke a cigarette proved* less irritating.

Philip Morris, due to the use of diethylene glycol, are less irritating than ordinary cigarettes in which glycerine is used as the hygroscopic agent.

APPROVED CLINICAL PATHOLOGISTS

American Medical Association Essentials for An Approved Clinical Pathologist

An approved clinical pathologist should be a licensed graduate of medicine. He shall have specialized in clinical pathology, bacteriology, pathology, chemistry, and other allied subjects for at least three years, and he should be reasonably familiar with the manifestations of disease in the body. The director of a clinical laboratory shall be on full time or have definite hours of attendance, devoting the major part of his time to this specialty. A clinical laboratory is an institution organized for the practical application of the fundamental sciences by the use of specialized apparatus, equipment and methods, for the purpose of ascertaining the presence, nature, source, and progress of disease in the human body.

The following Clinical Pathologists directing private laboratories in California are approved by the Council on Medical Education and Hospitals of the American Medical Association:

Clinical Laboratory of Drs. W. V. Brem, A. H. Zeiler, Roy W. Hammack and G. D. Maner, 657 So. Westlake Avenue, Los Angeles, California.

Zera E. Bolin, M. D., 490 Post Street, San Francisco, California.

These laboratories use standard methods and are fully equipped to make all clinical examinations of recognized value in: Tissue Pathology, Bacteriology, Hematology, Serology, Bio-Chemistry, Kolmer Wassermanns, Kahn test, Medico-legal, Basal metabolism, Blood chemistry, Hormone Test for Pregnancy, Parasitology, Cardiology, Autogenous vaccines, etc.

25 years have passed...

and the flame burns bravely on

Founded in 1911, on philanthropic grants, the Dermatological Research Laboratories have been dedicated, during this first quarter of a century, to wide public service.

From its earliest studies of cutaneous therapy to the most recent discoveries in the field of antisyphilitics, this institution has labored selflessly for the advancement of medicine and the furtherance of human health. Consistently, the Directors of D-R-L have mined the minds of an able staff, seeking better formulae and safer, more effective methods.

The brilliant record of these Laboratories constitutes a thrilling romance. To their credit are many new chemical compounds, including one of the first organic mercurial germicides which proved to be of practical usefulness to physicians.

Turning temporarily from mercury, D-R-L began a study of arsenic compounds—an investigation impelled by the War-time embargo on German products. Duplicating the intricate foreign formula of arsphenamine, these Laboratories soon became virtually the sole source for Army, Navy, and civilian needs.

Following this triumph with the first American-made Neoarsphenamine (66 per cent above U. S. Public Health requirements, by prescribed toxicity tests) D-R-L then developed Bismarsen (Bismuth and Arsenic in true organic combination) and followed this original research product with the creation of Bismo-Cymol, the first lipo-soluble Bismuth compound for treatment of syphilis made in America.

And now, what of the *next* quarter of a century? Who can say what the years to come hold? Only this we know: D-R-L goes confidently forward, actuated by the same unselfish motives, the same high ideals that have proved such a guiding and sustaining force throughout the years which have gone by.

D·R·L DERMATOLOGICAL RESEARCH LABORATORIES, PHILADELPHIA, PENNSYLVANIA • DIVISION OF ABBOTT LABORATORIES • NORTH CHICAGO, ILL.

First laboratory in America to produce Arsphenamine—Neoarsphenamine—Sulpharsphenamine—a bismuth preparation for intramuscular injection. Originators of Bismarsen—Bismo-Cymol—Metaphen—Campiodol Emulsion and other outstanding chemotherapeutic specialties.

EDITORIALS[†]

"SAN FERNANDO PLAN" OF LOS ANGELES COUNTY*: ITS EFFICIENCY IN THE OUT-PATIENT MEDICAL CARE OF INDIGENT CITIZENS

How the "San Fernando Plan" for Outpatients Came Into Existence.—From time to time during the last three years, CALIFORNIA AND WESTERN MEDICINE has presented editorial and other comment upon a new experiment, inaugurated in 1933 by the County of Los Angeles, whereby, under authority of the Board of Supervisors, out-patient medical care was given to indigent citizens in the private offices of physicians. First tried out in the San Fernando Valley, this so-called "San Fernando Plan" has served a territory including nine districts not a part of the metropolitan area of Los Angeles County.

In 1924, the County Health Department started its first "Health and Welfare Center," and soon nine such headquarters were instituted, each provided with a modern building adapted not only for preventive, but also with limited curative facilities. Prior to that time, ambulatory patients of these districts went for care to the out-patient service of the Los Angeles County Hospital, or to medical school and other dispensaries.

* * *

The Protest Against the County Health Department's Health Centers.—At the end of several years, however, the manner in which these "Health Centers" were administered by the County Health Department provoked protests from local physicians who had been invited to give gratuitous service in the attached clinics; and, as a consequence, based on a legal opinion rendered by the County Counsel in June, 1932, the curative clinics were again placed under the jurisdiction of the Los Angeles County Hospital.

* * *

The Proposal Made by Physicians of the San Fernando District.—Meanwhile, members of the medical profession in the San Fernando district having found the clinic work onerous, since many indigent patients used the kindly health-center building as a sort of social and gossiping center, a proposition was, therefore, made to the County Board of Supervisors that treatment no longer be given in hospitals, but in the offices of the physicians. On August 1, 1933, this new method was inaugurated at San Fernando, for a ninety-day trial; and on its recognition as a seeming improvement, it took on a more expanded and permanent form, six of the remaining districts also coming under its regulations. In this new method, physicians were compensated (supposedly for the use of office and equipment) at the rate of 50 cents for each office visit, while for home visits a rate of $1.50 plus mileage was allowed. In 1934, it was estimated that the average cost per office call was $1.236, and a year later, in December, 1935, the county paid to physicians a total of $38,782 to cover 22,951 office calls and 1,796 trips to patients' homes.

[†] Editorials on subjects of scientific and clinical interest, contributed by members of the California Medical Association, are printed in the Editorial Comment column, which follows.

* Articles on the San Fernando plan were printed in CALIFORNIA AND WESTERN MEDICINE, as follows: Issue of December, 1933, on page 417; January, 1935, on page 16.

* * *

A Recent Survey of the San Fernando Plan. Attention is again called to the San Fernando plan, not only because of the publicity given to it within and without the state, but also since the Department of Budget and Research of the County of Los Angeles has just brought off the press a report of 200 pages dealing largely with the scheme's workings. In this report it is estimated that an annual saving of something like $153,748 could be made, if certain modifications of the plan were instituted. The present annual cost of $621,308, for example, is divided between $355,308 for administrative personnel and an estimated $266,000 for office treatments; whereas it is believed that a saving of $20,748 would result on administrative personnel, and quite $133,000 on office treatments.

This lesser estimated cost of office treatments is based on a proposed method to greatly reduce the number of physicians on San Fernando panels, thus practically approximating full-time medical employees to give treatments in the health centers, or in emergency work, or in house visitations. The report also expresses the opinion that the San Fernando plan, as conducted in the past, is in violation of the county charter, the Research Department critics contending that panel physicians should be civil service employees.

Whatever one thinks of the foregoing propositions, some of the other suggestions of the Department of Research and Budget are of merit, and might well be adopted, although, for lack of space, they will not be discussed here.

* * *

Is the San Fernando Plan, as Now in Operation, or Modified as Proposed, Desirable?—To most physicians, the question must naturally arise as to whether it is wise to publicize treatment plans incorporating a compensation table of fifty cents per office visit. Many laymen, upon learning of such a rate, are apt to draw the conclusion that adequate and scientific medical service can be economically rendered by physicians on that basis, forgetting that in all such plans as the San Fernando, the physicians in attendance, who also have private practice, must necessarily donate of both their office facilities, and their time and services, at that lower rate of pay.

In other words, is not such publicity a detriment to established scientific practice in medicine, and, if so, would it not be a wiser plan to have all curative work carried on under the immediate jurisdiction of the parent institution, the Los Angeles County Hospital, and through its full-time, salaried medical personnel? In the long run, which is the better method?

The study of the Department of Budget and Research is a valuable report, and should receive due and careful consideration by all the interests involved.

ON HOSPITAL SERVICE IN THE UNITED STATES

Why Hospital Surveys Are of Interest.—Just when plans for hospitalization and medical service, operating under the sponsorship of physicians and hospitals and to the number of more than two hundred, are being thoroughly tested in different parts of the United States, and when, at the same time, lay and political propagandists are continuing throughout the Union their efforts to bring about the enactment of laws that would lay the foundation for compulsory health insurance and state medicine, it may not be out of place to review some of the facts having to do with hospital service in the United States.

Fortunately, accurate statistics on hospital standards and facilities are available, the American College of Surgeons having started its surveys in 1918, and the Council on Medical Education and Hospitals of the American Medical Association in 1921—the College having for the year 1935 an "approved" group of 2,266 out of 3,565 institutions surveyed in the United States and Canada, and the American Medical Association placing 6,246 hospitals, located in the United States, on its "registered" list; 564 institutions (representing 1 per cent of the total capacity of all hospitals) having been refused such registration recognition.

* * *

American Medical Association Standards for Hospital Registration.—Among such registration stipulations laid down by the American Medical Association are the following:

> Organization. — The organization should consist of a board of trustees or other supreme governing body having final authority and responsibility, and an executive officer or superintendent to carry out the policies adopted by the governing body. The executive officer should be assisted by adequate competent personnel.
>
> Regardless of the form of organization, the hospital should function primarily in the interests of the sick and injured of the community. . . .
>
> *Pathology.*—All tissues removed in the operating room should be examined, described, and diagnosed by a competent pathologist, excepting tissues such as tonsils and teeth, in which the pathologic changes are quite obvious.
>
> A physician-pathologist should be employed on a full-time or part-time basis. When this is not practicable, arrangements should be made with a consulting pathologist for tissue-diagnosis, postmortem work and the interpretation of the more complicated tests and determinations in

clinical and surgical pathology, as well as in general clinical laboratory work. The pathologist preferably should be one listed by the Council on Medical Education and Hospitals of the American Medical Association. . . .

Autopsies.—Every effort should be made to secure consent for autopsies, which should be performed by a pathologist or the best qualified other physician available.

Radiology.—The hospital should provide or have ready access to radiologic equipment and service. When a full-time or part-time physician roentgenologist cannot be employed, the services of such a consultant should be secured. Radiologic interpretations must be made only by a competent roentgenologist. A description of the roentgenologic examinations should be placed in the patient's chart. The physician-roentgenologist preferably should be one listed by the Council on Medical Education and Hospitals of the American Medical Association. . . .

Ethics.—In order that a hospital may be eligible for registration it will, of course, be expected that the staff and management conform to the principles of medical ethics of the American Medical Association with regard to advertising, commissions, division of fees, secret remedies, extravagant claims, overcommercialization, and in all other respects.

* * *

Minimum Standards of American College of Surgeons.—The American College of Surgeons has somewhat similar standards, among which are these:

1. That physicians and surgeons privileged to practice in the hospital be organized as a definite group or staff. Such organization has nothing to do with the question as to whether the hospital is "open" or "closed," nor need it affect the various existing types of staff organization. The word *staff* is here defined as the group of doctors who practice in the hospital, inclusive of all groups such as the "regular staff," the "visiting staff," and the "associate staff."
2. That membership upon the staff be restricted to physicians and surgeons who are (*a*) full graduates of medicine in good standing and legally licensed to practice in their respective states or provinces, (*b*) competent in their respective fields, and (*c*) worthy in character and in matters of professional ethics; that in this latter connection the practice of the division of fees, under any guise whatever, be prohibited.
3. That the staff initiate and, with the approval of the governing board of the hospital, adopt rules, regulations, and policies governing the professional work of the hospital. . . .
4. That accurate and complete records be written for all patients and filed in an accessible manner in the hospital. . . .
5. That diagnostic and therapeutic facilities under competent supervision be available for the study, diagnosis, and treatment of patients, these to include at least (*a*) a clinical laboratory providing chemical, bacteriological, serological, and pathological services, and (*b*) an x-ray department providing radiographic and fluoroscopic services.
6. That there shall be a properly organized nursing department under competent supervision and direction for the administration of the nursing service.

* * *

Annual Surveys an Incentive to Hospital Improvement.—A perusal of the above requirements, laid down by the two organizations—the American Medical Association and American College of Surgeons—which have been largely responsible for the phenomenal betterment of standards that has taken place in American hospitals during the last twenty years, reveals the phases of hospital service particularly stressed.

Today, members of the medical profession and patients alike expect to find hospitals measuring up to the standards established during the last two decades; and it may be affirmed that these two professional and lay groups are not satisfied with anything less.

Hospitals, in one sense, are high-class hotels catering to sick and injured persons, and possessing administrative, medical, nursing and other services and facilities, by means of which the attending physician is enabled to supervise the care of his patients with greater efficiency, and through which such patients are given a far better chance for earlier restoration of health than would be possible in the ordinary home.

* * *

Hospital Data of the American Medical Association Council on Hospitals.—The 6,246 hospitals have 1,076,350 beds and 53,310 bassinets, the average number of beds not used being 199,661, of which latter number 144,880 were credited to "general hospitals."

These general hospitals accepted 6,867,870 patients, or 89.07 per cent of the 7,709,942 patients admitted to all hospitals. . . . The average length of stay per patient in general hospitals was fourteen days. . . . There are 4,364 hospitals that have their own laboratories, 3,115 of which are directed by physicians, while 275 registered have nurses for directors. . . . Roentgen-ray departments were reported by 4,698 hospitals, with 3,686 physician-directors and 278 nurse-directors.

California is credited with 368 registered hospitals, 64,315 beds and 3,602 bassinets, and a total of 487,433 admissions, with an average census of 53,895.

California also has twenty federal hospitals, with 1,831 beds; sixteen state hospitals, with 21,326 beds; sixty-one county hospitals, with 17,339 beds; one city hospital, with ninety beds, and three city-county hospitals, with 2,174 beds; making a total of 101 governmental hospitals in California alone, with 47,578 beds, of which 44,415 are practically in constant use.

The total number of nongovernmental institutions for the sick in California is divided as follows: Forty church hospitals, with 4,598 beds; five fraternal, with 675 beds; sixty-one "nonprofit corporations or associations," with 5,017 beds; these together making a total of 106 nonprofit hospitals, with 10,290 beds, of which 6,235 are ordinarily occupied. In addition, the state has 161 proprietary hospitals, with 6,447 beds, of which 3,245 are in use.

* * *

Amount of Capital Investment in the Hospitals of the United States.—It has been estimated that the registered hospitals in the United States represent a capital investment of more than three billion dollars, a sum which places hospital plant and equipment among the half-dozen major capital outlays of the Union. The per-bed investment runs from $2,500 (for chronic diseases) to $10,000 (for acute illnesses), making an average of about $5,000 per bed.

Federal and state hospitals are devoted largely to the care of mental and tuberculosis patients.

The endowment resources of nongovernmental hospitals are limited to a few institutions only, and is so inconsequential that, if distributed among all the hospitals of the country, "would provide about $0.08 per patient-day toward operating costs."

The above figures, taken from the survey reports to the American Medical Association, the American College of Surgeons and other sources, indicate what a large place hospitals have in the lives of both physicians and patients, and why proposals for hospitalization and medical service on a periodic-payment basis must give consideration to these institutions, since, necessarily, they are important elements in all such plans.

CHIROPRACTIC: A LEGAL OPINION ON ITS THERAPEUTIC SCOPE*

The Opinion Handed Down by Judge John J. Van Nostrand.—In the department for Original Articles, on page 419 of this issue of CALIFORNIA AND WESTERN MEDICINE, will be found an opinion rendered by the Honorable John J. Van Nostrand of the Superior Court of California, in and for the City and County of San Francisco, in which Citizen M. James McGranaghan, who holds himself before the public both as a chiropractor and an attorney-at law, sought to have the Court determine the diagnostic and treatment scope of his chiropractic license.

* * *

How Chiropractor McGranaghan Placed Himself on Trial.—In order to bring his case before the courts, the plaintiff, McGranaghan, alleged his license allowed him to do most of the things embraced in the practice of medicine. Chiropractor Berger intervened, claiming such a license permitted only a lesser scope of activity.

The People of the State of California, through Attorney-General U. S. Webb, also intervened, asking the court to determine, not who was right, but *what* was right.

Attorney-General Webb contended both parties sought to do more than the Chiropractic Act permitted its licentiates to do.

After a trial lasting approximately two months, during which the People's case was presented by Deputy Attorney-General Lionel Browne, the court determined neither chiropractor could perform the acts which they sought to perform. Most of the things they tried to do were held to come within the domain of medical practice.

Excerpts from the brief submitted by Attorney-General Webb and Deputy Attorneys-General Leon French and Lionel Browne are printed on page 414 of this issue.

* * *

The Decisive Nature of the Van Nostrand Opinion.—In the opinion which was handed down on September 28, 1936, Judge Van Nostrand states:

> I am not in accord with the position assumed by the plaintiff herein as to the unconstitutionality of the words "Materia Medica," for they have a well-defined and recognized meaning, and have been frequently used by the courts of this state, and consequently I hold that the chiropractor has no right to administer or prescribe drugs or medicines. . . .
>
> Such appliances or agencies as the chiropractic table, chiropractic hammer, and towels and other instrumentalities as are purely sanitary, do not violate the statute; but the use of the various therapeutic agencies, such as electrotherapy, hydrotherapy, colonic therapy, etc., are embraced in the practice of medicine and, therefore, forbidden to chiropractors.

To many readers, the opinion of the Honorable William P. James of the Superior Court of San Jose, to be found on page 142 in the February, 1934, issue of CALIFORNIA AND WESTERN MEDICINE, in a case reversed for technical reasons, may be of special interest, because of a point of view similar to that of Judge Van Nostrand.

* * *

Thirty-five Hundred California Chiropractors Also Should Be Interested.—The Chiropractic Practice Act became a law by initiative vote of the California electorate in 1922, and since that date the Chiropractic Board has licensed almost 3,500 practitioners of that cult. It is a hopeful sign that a higher court has seen fit to define the limitations of the law. It may be of interest to note to what extent chiropractors will abide thereby. It is not known, at the time of this writing, whether an appeal will be taken.

"PACIFIC COAST ABORTION RING"

A Recent Exposé.—Reference to the column assigned to the California State Board of Medical Examiners, on page 448 in this number of the Official Journal, discloses a series of newspaper items concerning what the press has styled a "tri-state illegal operations syndicate," referring to Washington, Oregon and California. The parties accused of the guilty acts, having been haled into court, are on trial before the Honorable Arthur Crum, judge of the Superior Court for the County of Los Angeles. Because of the astounding nature of the evidence which has been submitted, the case has received much mention in the newspapers.

The "syndicate" secured, among other activities, the coöperation of a former enforcement officer of the California Board of Medical Examiners, now for the time being committed to jail by the Court because of his efforts to intimidate witnesses for the State.

* * *

Brazenness of the Group.—The leaders of the syndicate, indeed, became so brazen that they even gave defiance to the California Examining Board, in the belief that the safeguards and loopholes, which their legal counselors had advised them to use in their operations, would be sufficient to protect them from attack by the State's authorities. The syndicate's plan of operation was originally conceived by a lay citizen of the State of Washington, a lumberman who went so far as to create a "Medical Acceptance Corporation" (after the style of automobile financing agencies); so that payments, with rates of interest appropriate under the circumstances, might be secured from some of the patients. So-called clinics were established in about ten of the Coast cities. The money profits are stated to have approximated an annual sum of something like one million dollars!

---

* The brief submitted by Attorney-General U. S. Webb appears on page 414; the legal opinion handed down by Judge John J. Van Nostrand is given on page 419. Both articles are worthy of perusal by all licentiates.

A perusal of the newspaper items in the State Board column reveals the sordidness of the entire business. The jury's decision in the premises will be of interest. Present indications point to a long and bitter battle in the courts.*

Other State Association and Component County Society News.—Additional news concerning the activities and work of the California Medical Association and its component county medical societies is printed in this issue, commencing on page 430.

EDITORIAL COMMENT†

VENOUS PRESSURE

Determination of the venous blood pressure is at times of great value. In congestive failure, associated with failure of the right side of the heart, one of the first signs is increased pressure in the systemic or peripheral veins. Obstruction to a vein or venous channel will cause the pressure to increase distal to the site of the obstruction.

There are four fundamental factors affecting peripheral venous pressure, namely, (1) heart action, (2) intrathoracic pressure, (3) hydrostatic level, and (4) volume of blood in the vein.

Edema and the accumulation of serous fluid occasionally offer diagnostic problems. Determination of the venous pressure and estimation of the blood-plasma-proteins (indirect estimation of the approximate osmotic pressure of the blood) are usually of great help in the differential diagnosis between congestive heart failure, venous obstruction, and the edema of renal disease, depleted nutritional states, blood-loss and certain other metabolic disturbances.

There are two methods for determining venous blood pressure: (1) direct, and (2) indirect. The direct method is based upon a direct measurement of the pressure within a vein by means of a manometer connected with a needle or cannula introduced into the vessel. The indirect method depends upon the external pressure necessary to collapse a vein. The direct method should be chosen when reasonably accurate readings are required or when there is difficulty in obtaining a prominent pliable external vein. The vein chosen and zero level of the manometer tube should be horizontal to the mid-axillary line. This is approximately the level of the right auricle in the normal chest, with the patient in the recumbent position. This can be accomplished by using a long spirit level. The heart has been questioned as the point from which the hydrostatic factor in venous pressure is measured. However, for clinical purposes it is necessary to have a more or less fixed point or landmark to serve as, at least, a hypothetical zero level. The patient should rest in recumbency for at least fifteen minutes before the test. The manometer tube should have a bore not smaller than 4 millimeters. In the direct method a needle of 18 gauge is sufficient, and sterile aqueous solution of 2 per cent sodium citrate can be used to fill the small Kaufman-Luer syringe, rubber tubing and manometer to the level which is assumed to be the approximate pressure. All air should be excluded, and the plunger of the two-way syringe pushed in to the closed position. The needle is introduced well into the lumen of the vein. The plunger of the syringe is then withdrawn to the sidearm of the syringe, allowing the blood stream to be in direct contact with the manometer tube.

In patients suffering from congestive heart failure it is not uncommon to obtain readings of from 20 to 30 centimeters and occasionally even higher by the direct method described. Under normal conditions of tissue resistance, capillary permeability and osmotic pressure, the edema level of the venous pressure, as measured in one of the large superficial veins of the flexor surface of the elbow, is from 16 to 18 centimeters of the citrate solution. The normal pressure in this vein varies from 4 to 12 centimeters.

The pressure in the venule loop of capillaries is the most important factor in the production of edema of cardiac origin. This venule pressure is difficult to obtain, and at the present time it is not practical to obtain this reading for routine clinical use. The venule pressure is greater, but parallels the venous pressure in rise or fall.

Some clinicians obtain a rough estimation of the venous pressure by observing the level above the heart at which the superficial veins of the hand will collapse.

Serial determinations of the venous blood pressure are of great value in estimating the response of a patient suffering from congestive failure of the right side of the heart.

Dudley W. Bennett,
San Francisco.

DETERMINATION OF BLOOD VELOCITY BY THE SODIUM DEHYDROCHOLATE METHOD

There are available four principal methods for the estimation of the speed of blood-flow in humans. These are: (*a*) The radium method of Blumgart,[1] in which radium emanation is injected intravenously and its arrival in any given part of the circulation is recorded by a radium-sensitive instrument. This method has the particular value of providing means for estimating separately the speed of the flow of blood through the lungs and through the peripheral vascular area; (*b*) the cyanid method of Robb and Weiss,[2] in which sodium cyanid is injected intravenously and its arrival at the carotid sinus is marked by a sudden increase in rate and depth of respiration; (*c*) the dye (vital red) method of Hamilton,[3] in which arm-to-femoral circulation time is measured by injecting the dye in an arm vein and collecting samples of blood by puncture from the femoral artery; (*d*) the sodium dehydrocholate method of Winternitz,[4] which depends for its measurement of the blood flow on the time taken for the bitter-tasting bile salt to reach the tongue after injection into one of the antecubital veins.

---

* Editor's Note.—The trial came to a sudden end and the jury found eleven defendants guilty. A newspaper item on page 440 gives additional information concerning the penitentiary sentences imposed by the Court.

† This department of California and Western Medicine presents editorial comment by contributing members on items of medical progress, science and practice, and on topics from recent medical books or journals. An invitation is extended to all members of the California Medical Association to submit brief editorial discussions suitable for publication in this department. No presentation should be over five hundred words in length.

1. Blumgart, H. L., Gargill, S. L., and Gilligan, D. R.: Studies on the Velocity of Blood Flow, J. Clin. Investigation, 9:69 (Aug.), 1930.
—The Velocity of Blood Flow in Health and Disease, Medicine, 10:1 (Feb.), 1931.

The latter method is the simplest, safest and most readily available. It is highly accurate in comparison with more elaborate methods. In contrast with the above mentioned techniques, the sodium dehydrocholate method requires the coöperation of the patient in establishing the end-point.

Recent investigations[1, 5] have shown that the rate of blood flow is slowed in myxedema, polycythemia vera and in congestive cardiac failure, and is accelerated in anemia and in hyperthyroidism, but not when the metabolic rate is elevated with dinitrophenol[6]).

The blood velocity is determined by injecting 5 cubic centimeters of the 20 per cent solution of sodium dehydrocholate rapidly into one of the veins of the cubital fossa. The time between the beginning of the injection and the appearance of a bitter taste in the mouth is recorded with a stopwatch and gives one the arm-to-tongue circulatory time. Sixteen gauge needles are used and the determinations are always done in duplicate. Not more than one or two seconds should be taken in delivering the 5 cubic centimeters of testing fluid into the vein. The normal blood velocity, as measured by the above technique, is from 10 to 16 seconds, the average being 13. Duplicate determinations usually check to within one second. The test should be done with the patient in a basal condition, as for a determination of the basal metabolic rate.

INJECTION TREATMENT OF HERNIA: ITS EXPERIMENTAL BASIS*†

By Franklin I. Harris, M.D.
and
Alfred S. White, M.D.
San Francisco

In the past few years much interest has been aroused in the possibilities of treating hernia by a nonoperative method. Despite the fact that thousands of cases of hernia have been and are being treated by a method of injection, there has been very little scientifically conducted investigation to determine the value or dangers of such a method of treatment.

HISTORICAL BACKGROUND OF INJECTION TREATMENT

A study of the historical development of this subject and an analysis of the work which has been done by various investigators may explain the prejudice against this form of therapy. Since its first introduction by George Heaton in 1832, it has been alternately advocated and condemned. A study of the papers which have appeared on this subject reveals independent attempts by different investigators who have failed to base their work upon the experience of men who have preceded them. Perhaps it is this lack of correlation, this failure to build upon the experience of others, which has prevented the popularization of this treatment. Previous reports show an amazing lack of critical analysis, a failure to evaluate statistically the results of the treatment. The criticisms of the opponents of the method led not to a more careful evaluation of results, but rather to an exaggeration of claims which, in the first place perhaps, were extravagant.

HEATON'S CLAIMS

Following Heaton's claim of 100 per cent cures in his private practice, the American Medical Association sent a committee requesting information about his work; this he refused to give. This failure to reveal his exact technique to the medical profession brought him and the method much justifiable criticism. His results, which were finally published in 1843, reveal a complete lack of critical analysis and statistical interpretation. He states in his book that all of his patients were cured; but from comments and criticisms of contemporary men it seems apparent that he was successful in only about 75 per cent of his cases. Little additional work was done in this country in the succeeding few years, although Bigelow, in 1850, and Watson, in 1851, published single articles. Owing to the prejudice with which Heaton's work was received, he spent little time in introducing it in this country. On a European trip, however, he demonstrated his work in England, France and Germany, and subsequent articles in the foreign literature appeared as a result of his teaching. Little advance was made in this form of therapy until about 1880, when Warren and DeGarmo attempted to popularize Heaton's technique. Largely on the basis of their work, renewed interest was shown in Europe. Schwalbe and Steffen in Germany, and Lannelongue in France, were the principal proponents.

† Discussion of the three papers on the Injection Treatment of Hernia appears on page 395.

PINA MESTRE'S WORK

In 1910 there appeared some work by Pina Mestre of Barcelona, Spain, which marked the introduction of the modern scientific conception of this subject. The criticisms, dangers, complications, and results of the old method do not in any sense apply to the injection treatment as now proposed and advocated. The discussion of caustic solutions, such as iodin, tincture of cantharides, extract of white-oak bark, alcohol, and carbolic acid, which were previously used, and the untoward reactions and occasional fatalities of previous investigators and a discussion of the paraffin injection treatment of the latter part of the nineteenth century, do not form a part of an analysis of the modern method. The necrosis and sloughing, the atrophy of the testes, fecal fistula, peritonitis and failure to cure, occasionally experienced by investigators using the old method, are not a part of the experience which has been found with the injection method of today.

OTHER STUDIES AND REPORTS

In the last few years able surgeons have quietly and cautiously investigated the possibilities of this technique. Reports are beginning to appear in the English and European, as well as in the American literature, of the successful treatment of thousands of cases, with good follow-ups and without any untoward results.[1,2,3] However, up to the present time there is still lacking an adequate presentation of the pathologic and histologic background, of statistical results and of an anatomical basis of the method. It has been our purpose to present a rationale of treatment based on anatomic and pathologic studies, and to study a carefully followed group of cases. We further propose to present a finished technique and to determine the contraindications and dangers of the method. In order to understand properly the rationale of such a method of treatment, one must for the moment briefly review the mechanism of the ordinary inguinal hernia.

MECHANISM OF HERNIA

An understanding of the anatomical relationships of the muscles, fascial layers and hernial sac in the indirect inguinal type of hernia is absolutely essential. The hernial sac, as is known, enters the inguinal canal through the internal ring and passes downward in the canal beneath the transversalis and internal oblique muscle. In the medial third of the canal it emerges from beneath the lower edge of the internal oblique muscle and lies then deep to the external oblique muscle. Deep to the sac lies the transversalis fascia. If external pressure be applied over the inguinal canal so as to approximate these muscle layers, the contents of the sac are unable to descend. This is often seen clinically in patients who exert pressure over the inguinal canal when sneezing or coughing. In other words, the hernia does not become clinically apparent until the contents of the sac descend within the sac itself. It is obvious that there must be a sufficient separation of the external and internal oblique muscles from the transversalis fascia to allow for the distention of the inguinal canal by the contents of the sac. If, then, by any means we can prevent the external oblique from separating from the underlying muscles, the hernia will never descend despite the existence of a sac. This is exactly the result obtained by the injection into this region of a solution which produces fibrosis. Such fibrosis obliterates the patency of the inguinal canal by producing an intimate adherence of the muscle layers in this region in a manner almost identical to that accomplished by the suturing of the surgical procedure.

SOLUTIONS FOR INJECTIONS

The solution to be used for the injection is our next consideration. The various solutions used in the past were unsatisfactory, as they produced too severe a form of inflammation in the inguinal canal. As the inflammation subsided, adhesions were formed which bound together the muscles constituting the inguinal canal and obliterated it by dense scar tissue. An inflammatory reaction sufficient to produce this result, however, carried with it a danger of untoward systemic reactions and local sloughs. The solutions used in the past based on such a principle were strong caustics such as phenol, iodin, and others mentioned above.

The principle underlying the more modern solutions is entirely different.[4] The solutions are relatively nonirritating, do not produce a severe inflammatory reaction and they appear to be noninjurious to tissue. They produce no systemic reaction from their absorption and are relatively nontoxic if mistakenly injected intravenously. Furthermore, they produce no peritoneal inflammation if through errors in technique they are injected into the peritoneal cavity. By experimental work and clinical results the modern solutions have proved to produce a predominance of the proliferative phase of the inflammation resulting in fibroblastic formation with the minimum of the exudative stage.

EXPERIMENTS WITH THREE TYPES OF SOLUTIONS

In this series three preparations have been used; the first two are alcoholic solutions of tannic acid, examples of which are the commercial preparations Pina Mestre Solution and Proliferol, and the third is a five per cent sodium salt of the fatty acids of oil of psyllium, the commercial preparation being known as Sylasol.

Before these solutions were used on patients a series of experiments with animals was made; first, to study the nature of the response of the tissues to the injected solution, and, second, to demonstrate the amount of fibrous tissue produced.

Identical experiments were run on each of the three solutions under discussion. Normal guinea pigs were injected with each solution in the thigh muscles at varying intervals. The solution was injected throughout the entire muscle of the thigh in order to give uniform infiltration. The specimens were obtained by disarticulation of the leg at the hip, and the entire leg fixed in formalin. Sections were then obtained and stained with hemotoxylin and eosin and modified Masson's stain. One-half cubic centimeter of each solution was used and sections were taken at 6 and 24-hour intervals, and at 7, 14, 26, and 75-day intervals. Generally speaking, the tissue response to these three different solutions was practically identical and a description of one will suffice for all.

At six hours there is a zone of marked polymorphonuclear infiltration associated with interstitial edema. The muscle fibers are fragmented, slightly irregular in size and shape, and have lost some of their finer structural details. Occasional small mononuclear cells accompany the polymorphonuclear neutrophils.

At twenty-four hours scattered regions show marked interstitial edema and polymorphonuclear leukocytic infiltration. Mononuclear cells are also present. Some muscle fibers have undergone hyalin alteration of the sarcoplasm.

Examination of the seven-day section reveals an inflammatory reaction in the connective tissue septa and the fat between the muscle bundles with little further alteration of the muscle fibers. Large undifferentiated mononuclear cells replace the fat and connective tissue. The polymorphonuclear neutrophils have disappeared, and a few lymphocytes and plasma cells are present. These undifferentiated cells ultimately become fibroblasts.

At fourteen days there is a proliferation of edematous fibrous tissue separating and replacing the slightly distorted muscle fibers. This fibrous tissue is present in large masses, and special stains reveal permanent collagenous fibrils. In this fibrous tissue are a few scattered mononuclear cells and lymphocytes. The muscle fibers in the zone of reaction are irregular in shape and have lost the transverse striations.

Section at twenty-six days shows the fibrous tissue to be more compact, due to the increase of collagen, and the fibrous bands are seen extending between the muscle fibers. Groups of small vessels and nerves are surrounded by the proliferating fibrous tissue. Undifferentiated mononuclear cells are present around small vascular channels.

By seventy-five days the fibrous tissue is seen in very compact bands which are separated by a slightly edematous tissue containing foci of phagocytic and mononuclear cells.

RECAPITULATION ON STUDIES

To recapitulate, an attempt has been made to simulate and study the reaction that probably occurs in human subjects. By sacrificing animals at varying intervals following injection, a composition picture was obtained. The primary cellular response to the solution is a purely leukocytic infiltration, which is shown at the six-hour specimen. By twenty-four hours there has been an introduction of the mononuclear elements which from that time on distinctly predominate. Marked edema is present in both the six and twenty-four-hour specimens. The reaction in general shows the superficial part of the muscle bundles to be involved with a slight destruction of the fibrillae of individual fibers. After twenty-four hours the cellular reaction proceeds, with the large undifferentiated cells progressing toward spindle shapes and then typical fibroblasts with collagen formation. The undifferentiated cells may remain scattered throughout and slowly disappear. Some take on phagocytic activities and hold hemosiderin. They are usually present around blood vessels, some probably differentiate toward endothelial cells and form the numerous capillaries in the proliferating fibrous tissue. The fibrous tissue is very edematous at first, with rare collagen fibrils between the star-shaped cells. As the lesion progresses it tends to form whorls and bands, composed of the typical spindle-shaped fibroblasts which are separated by well-formed collagen. Polymorphonuclear leukocytes are not encountered in the inflammatory reaction after twenty-four hours, but lymphocytes and plasma cells are usually noted. Hemosiderin increases in quantity as the lesion grows older. In the early lesions there is marked dilatation and engorgement of the capillaries. The main mass of proliferating fibrous tissue is usually present in the connective tissue septa and fat adjacent to the large muscle bundle, with only moderate replacement of the muscle. Nerves are frequently surrounded by this fibrous tissue.

COMMENT

To summarize, these solutions provoke an immediate polymorphonuclear leukocytic response of short duration, followed by a gradually increasing reaction from the mononuclear mesenchymal elements which finally differentiate into spindle-cell fibroblasts resulting in marked fibrosis. Such a production of scar tissue without tissue damage demonstrable is exactly our clinical objective.

An attempt was also made to determine the reaction of these solutions when placed within the peritoneal cavity. Guinea pigs were injected with varying amounts of solution in dosages relatively much greater than those which would ever be used in a human subject. Normal guinea pigs were injected with one-half cubic centimeter and one cubic centimeter of these solutions intraperitoneally and examinations made six, twenty-four, and seventy-two hours and seven and fourteen days following the injection. Microscopic examination with all three solutions show an occasional small amount of clear fluid in the peritoneal cavity, with no evidence of adhesions. Microscopic examination of the peritoneum and abdominal organs was entirely negative except for slight swelling of the mesothelial cells lining the peritoneum in the six- and twenty-four-hour specimens and slight subperitoneal fibrosis in the older specimens.

Theoretically, then, if one is able to produce a proliferation of new fibroblastic tissue into the inguinal canal by the injection of non-injurious solutions such tissue can be so placed as to obliterate the inguinal canal. To prevent destruction of this newly formed connective tissue by distention of the canal brought about by frequent descent of the sac contents, it is essential during the process of active treatment that constant external pressure be maintained over the muscles of the inguinal region. This can be easily accomplished by the use of a satisfactory truss. Such a truss must keep the sac contents completely and constantly reduced during the entire active period of treatment in order to give the newly formed connective tissue in the region of the inguinal canal time to firmly and strongly organize.

TRUSSES

The truss which has been found to be most satisfactory is that of the semi-rigid type with low counter pressure posteriorly over the buttock and a sponge rubber pad anatomically fitted to the inguinal canal. The right angle counter pressure with the lower fulcrum over the buttock is an extremely important factor, inasmuch as it directs the pressure through the pad and through the inguinal canal at right angles to the axis of the canal. The truss is so adjusted as to place the encircling band halfway between the crest of the ilium and the trochanter of the femur. This neutral point is above the active muscles of the thigh and below those of the abdomen. The correct placing of this encircling band together with the anatomically correct pad, and the additional support and counter pressure of the low posterior fulcrum, give an extremely satisfactory truss with the maximum of comfort to the patient and a minimum of harness. The muscles of the inguinal canal, whether in a direct or an indirect hernia, are completely held in approximation, thus completely closing the canal and maintaining the reduction of the hernia.

Variations of this type of truss are available and are satisfactory. The majority of trusses on the market, however, are not of this type and are entirely unsatisfactory. The spring scrotal truss, either the French, German or English type, the Chase truss and the elastic truss embody within them defects which contraindicate their use.

IN CONCLUSION

It is on these three principles just outlined that the modern scientific basis of the injection treatment of hernia depend. First, a knowledge of the mechanism of inguinal hernia; second, an understanding of the principle of producing new connective tissue by the injection of nontoxic, noninjurious solutions; and third, the necessity of constant external pressure produced by a truss to prevent the descent of the sac contents while such connective tissue is organizing.

TREATMENT OF HERNIA BY THE INJECTION METHOD[*][†]

By Frank R. Girard, M.D.
San Francisco

FOR the past one hundred years attempts have been made to cure hernia by the introduction into the inguinal canal of some caustic substance, or combination of substances, which would produce a chemical inflammation and result in scar tissue, thereby closing the canal. The chemicals used were often so powerful that abscesses were produced, followed by destruction of tissue, peritonitis, and at times fatalities. The ethics of these gentlemen were often very questionable, and they justly received the condemnation of the medical profession for their efforts. No animal experiments were done to find a nontoxic, noncaustic solution. No histologic examinations were made to prove that normal connective tissue was really produced, and the entire procedure was unscientific and doomed to failure.

STUDIES IN RECENT YEARS

During the past few years, however, interest has been revived in the cure of inguinal hernia by the injection method by men whose standing is unquestioned. Much experimental work has been done on animals to prove that the solutions used were nontoxic when injected into the peritoneal cavity, and even veins. Also tissue has been examined histologically from a few hours after injection to several months, showing the gradual development from a plastic exudate in the recently injected cases to a fibrous tissue proliferation from its early stages, in which the greater part of the tissue consists of young fibroblasts to the mature stage when the fibroblastic tissue has been converted into dense non-elastic fibrous tissue, in no way distinguishable from normal connective tissue.

EVALUATION OF SOLUTIONS

With these facts in mind it seemed altogether proper to attempt clinically to treat hernia by injecting the inguinal canal. To evaluate the merit of the various solutions offered, it was decided to inject the first seventy-five patients with Pina Mestre Solution. The second seventy-five patients were to be injected with Proliferol, reinforced by tincture of Thuja, phenol, and alcohol. The third seventy-five patients are now being injected with sodium psylliate (Sylasol).

The Pina Mestre Solution contains the following ingredients expressed in percentages: 25 per cent Krameria, 16 per cent Catechu, 15 per cent Rosa Canina, 15 per cent Rosa Centifolia, 14 per cent Vaccinium Myrtillus, and 15 per cent Monesia in 98 per cent alcohol. Proliferol is a distillate from the tinctures of several botanical herbs, to which is added thymol, tannic acid, and benzyl alcohol. The Thuja mixture consists of Lloyd's

Read before the General Surgery Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

[†] Discussion of the three papers on the Injection Treatment of Hernia appears on page 395.

Specific Tincture of Thuja 25 per cent, phenol 50 per cent, and alcohol 25 per cent. This is allowed to stand for forty-eight hours and then decanted. Sodium psylliate (Sylasol) is a 5 per cent sodium salt from the fatty acids of oil of psyllium.

Before beginning the treatment of patients, rabbits were injected intraperitoneally with ½, 1, 1½, 2, 2½, and 3 cubic centimeters of Pina Mestre Solution, and other rabbits were injected with the same dosage of proliferol. Following the injection the rabbits showed only slight reaction. When autopsied several days later, none of them showed any peritoneal reactions or adhesions, except the rabbits receiving the 3 cubic centimeters dosage, and that reaction was only a mild congestion of the peritoneum and intestines.

SELECTION OF PATIENTS: SUITABLE TYPES OF HERNIA

It is absolutely essential to know what type of hernia is suitable for the injection method and what type should be operated upon. In the first place, the hernia must be completely reducible into the abdominal cavity and be held there at all times by a properly fitting truss. Strangulated or incarcerated hernias are, of course, surgical. Any irreducible mass or suggestion of a mass in the inguinal canal should contraindicate the injection treatment. Undescended testicle and hernia associated with hydrocele are also surgical conditions. Asthma, hay fever, severe bronchial conditions, also prostatic hypertrophy, urethral strictures, and any condition causing straining during urination, should be relieved before attempting treatment by injections. The same holds true for cure by surgery. Overly stout patients with large pendulous abdomens, causing increased intra-abdominal pressure, should be reduced before attempting treatment. Hemophilia contraindicates injection. Diabetes, tuberculosis, hyperthyroidism, and syphilis may be treated, depending on the severity of the condition. Age is no contraindication. One of my most gratifying results was obtained in a man eighty-four years of age, with a large direct hernia of fourteen years' standing. During the middle of the treatment he went through an attack of bronchial pneumonia, without damage to the proliferation already obtained. Six weeks later the treatment was continued to a successful conclusion. Femoral hernias must be selected for treatment with extreme care, and the same holds true for umbilical and incisional hernias. These are often not suitable for the injection treatment, due to adhesions and the fact that there is no definite sac formation. Patients with nephritis, cardiac disease, high blood pressure and any condition causing debility, making them "poor surgical risks," can be safely treated.

TRUSSES

Any surgeon using the injection treatment for hernia must know thoroughly the technique of fitting trusses properly and what type of truss should be used for each individual case. One type of truss is not suitable for all patients, and if the fitting of trusses is left to the laymen without proper supervision, they are almost invariably fitted too low over the external ring, instead of the maximum pressure being at the internal ring. Not 10 per cent of the millions of trusses worn are properly adjusted. A semiframe truss with counter pressure over the gluteal region gives, as a rule, the most efficient pressure and the greatest comfort. Elastic trusses are not to be used. The truss should be worn tight enough so as to cause an indentation or depression at the inguinal canal, thus approximating as much as possible the anterior and posterior walls of the canal during the process of solidification. Occasionally a truss too tightly fitted will cause edema of the scrotum and enlargement of the cord, particularly a double truss. The truss should be worn day and night for at least one week before beginning treatment, which allows the patient to become accustomed to sleeping in it, and gives the surgeon opportunity to observe if the hernia is held properly reduced, and if the skin will tolerate the pressure of the pad. The truss is worn day and night next to the skin, during the treatment, and for one month after the treatment is finished. It is then removed at night, but replaced before the patient gets out of bed and worn during the day, from four to six months, depending on the patient's type of work. If blisters develop under the pad, they are easily treated with compound tincture of benzoin or dusted with bismuth formic iodid powder.

Occasionally one meets a large scrotal hernia which is impossible to retain properly reduced with any type of truss. With these patients I have put them to bed, kept the foot of the bed elevated, and given them from four to six injections at daily intervals, then adjust the truss, which will now hold the hernia perfectly reduced, and finish the treatment in the usual manner.

TECHNIQUE OF INJECTION

Before discussing technique it seems proper to discuss by whom this type of treatment should be used. I hold that its apparent simplicity is one of its greatest drawbacks, as this method requires as much if not more technical skill and surgical judgment than the operative method. It should be employed only by men surgically trained, with a knowledge of the anatomy and pathology of the inguinal region, and an accurate diagnostic ability. Unfortunately, men seeing only an occasional hernia in their practice, who would never dream of doing a herniotomy because of lack of surgical training, will be tempted to employ this treatment, resulting in danger and disappointment to the patient, and bring discredit on the method. It is as much a surgical procedure as operation. The technique is as definite and exacting. The same knowledge and skill are required, if not more so, the only difference being that a syringe and a solution are used instead of a scalpel and sutures.

With the patient reclining on the treatment table, the pubic hair is clipped and not shaved. The table is then tilted to a moderately steep Trendelenburg position, and the internal ring is located two centimeters up from the middle point, between the anterior superior spine of the ilium and the spine of the pubes. This area is painted with merthiolate or tincture of iodin. A five cubic centimeter Luer syringe is used with two needles. The needles vary from 1½ to 3 inches in length, depending upon the thickness of the abdominal wall, are 22-gauge, and short-beveled. Three cubic centimeters of 2 per cent novocain without adrenalin are drawn into the syringe. The skin is pinched up and the needle inserted at right angles to the abdominal wall, down to the fascia of the external oblique muscle. Then with steady, firm pressure, using the finger touch and not the weight of the arm, the fascia is punctured and there is felt a sudden "give," like the puncturing of the head of a drum. The needle is advanced one-quarter inch further, and the tip of the needle is then in the region of the internal ring. This can be demonstrated by the fact that the point of the needle can be moved around freely. Then aspirate to make sure that a blood vessel has not been punctured, and inject the novocain. The syringe is next detached from the needle which is left *in situ*. The second needle is then attached to the same syringe and four cubic centimeters of the solution to be injected is drawn into the syringe. After a lapse of five minutes, to give the novocain time to act, the second needle is detached and the syringe is attached to the needle inserted into the internal ring, again aspirating to make sure that the needle has not changed position. The solution is injected very slowly. At times patients will notice a warm feeling in the area injected, and sometimes a stinging feeling in the penis and scrotum. This is due to the solution irritating the ilio-inguinal nerve, which lasts only a moment and is not severe. If during the injection the patient should complain of severe pain ascending up the abdomen toward the umbilicus, the injection should be immediately stopped, because that generally means that some of the solution has entered the peritoneal cavity. If this should happen, patients may complain of abdominal cramps and nausea, but this rarely lasts more than one-half hour. After the needle is withdrawn, the injected area is gently massaged with a small gauze sponge. This frequently increases the hot feeling for a moment. A small piece of adhesive plaster, one-half centimeter square, is then placed over the site of the puncture as a marker. The patient remains quiet for about ten minutes longer. The truss is then carefully adjusted. The table is leveled and the patient is helped to the upright position by supporting the shoulders. This takes the strain off the lower abdominal muscles. The truss is then inspected with the patient standing. He then returns to his work.

FREQUENCY OF TREATMENTS

The treatments are given three times weekly, but may be given daily if the reaction is slight and time is a factor. Occasionally a patient has to miss a treatment, which is not important. Some patients complain of a lameness in the inguinal region for the following twelve hours, but it is rarely severe enough to incapacitate them for work.

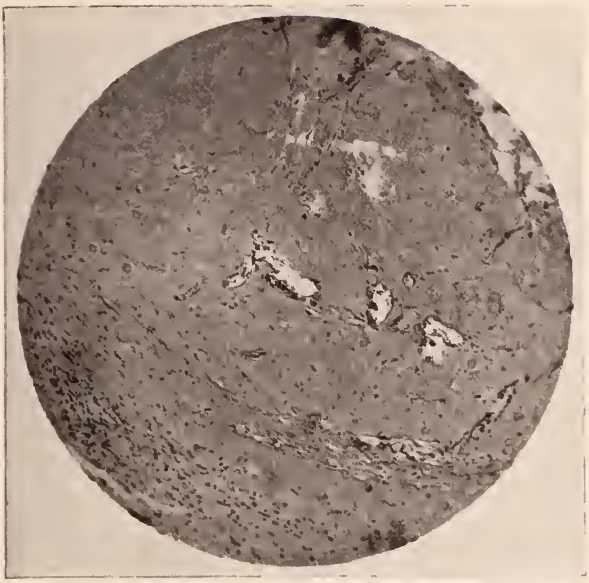

Fig. 1.—Microphotograph of tissue taken from patient who had received thirty-six injections. Note the very dense and markedly hyalinized tissue, with a minimum amount of cellular reaction. The tissue formed as a result of the injections is a cross between a scar and a keloid.

I like to begin the treatments at the internal ring for the following reasons: The internal ring is the most important area to obliterate, and the sooner the better. With the internal ring narrowed, the truss can better be depended upon to keep the intestines within the abdominal cavity at all times. If the external ring is injected last, one can often insert the index finger through the external ring up into the canal and insert the needle down to the tip of the finger. Then the cord lying posterior to the finger cannot possibly be injected. This gives one a better control of the situation. After the first injection at the internal ring, the canal is injected downward, the injections being given about 1½ centimeters apart, toward the external ring, with the finger in the canal whenever possible. Several injections are given as a routine into Hesselbach's triangle, and the external ring is injected lastly. The internal and external pillars and the arch are injected, with the finger pushing the cord out of the way.

I have found twelve treatments to be necessary on the average, although some patients may require fifteen or even twenty treatments, and others only eight or ten. There is a marked difference in the way patients react regarding proliferation; the negro proliferating more rapidly than the white man because of the tendency to keloid formation. The average patient receives three injections at the internal ring, four in the canal, two in Hesselbach's triangle, and three in the region of the external ring. In direct hernias the injections are given first in Hesselbach's triangle, with the index finger in the external ring as a guide. The edge of the defect in the conjoined tendon can often readily be palpated and elevated a bit, and injected down to the tip of the finger. In treating direct hernias a few injections are always given into the inguinal canal and the internal ring.

COMBINATIONS OF SOLUTIONS

For the past year I have been using the Thuja mixture to enhance the proliferating action of the solutions used. I find that a better proliferation is obtained than when Pina Mestre Solution and Proliferol were used alone. When using the Thuja mixture, a tuberculin syringe is used, and never more than six minims of this powerful mixture are used for an injection. The Thuja is employed at every fourth injection. So for the patient receiving twelve injections, the fourth, eighth, and twelfth injection would be the Thuja Solution. When using Sylasol, no local anesthetic is needed. The injection consists of three cubic centimeters in amount. The same technique is used as with Proliferol, but no Thuja Solution is used with Sylasol. Since using Sylasol, I have noticed that the proliferation seems more abundant and develops more rapidly than when either Pina Mestre or Proliferol was used. After eight to ten injections it is often difficult to give further treatments because of the density of the tissues.

A VARIATION IN THE METHOD OF INJECTION

A method of injecting has been advocated whereby the needle is inserted several centimeters above the site of injection. The needle is inserted into the skin at about a 45-degree angle. The point of the needle is directed downward toward Poupart's ligament. The perineal cavity is supposed to be less apt to be entered than when the needle is inserted at right angles to the skin. It is supposed to be a safer method for beginners. That may be true, but one must remember that the cord rests on Poupart's ligament, and is more apt to be damaged than by injecting into the center of the canal.

CONDITION OF TISSUES WHEN TREATMENTS HAVE BEEN FINISHED

When the treatment is finished, we expect to have the following changes in the inguinal canal: The external and internal oblique muscles which have been separated from the transversalis fascia by the protruding bowel are now solidly welded together with the Cremaster muscle and the spermatic fascia, and the loose areolar tissue in the inguinal canal. A dense fibrous tissue inguinal splint is developed. With the exception of the hernial sac not being removed, this should give the same end-results as an operation. I believe that in many patients the sac becomes obliterated by the walls fusing together, due to the chemical inflammation extending from the surrounding tissue through the walls of the sac. Eventually the sac is transformed into a fibrous band.

REPORT OF CASE

At autopsy it has been found not infrequently that a hernial sac extends down on the cord. These men were never conscious of having had a hernia, and never had symptoms of a hernia because the neck of the sac was so constricted that the abdominal contents were never able to enter the sac. By narrowing and solidifying the inguinal canal, we do exactly the same thing to the sac. Unless the neck of the sac can be completely obliterated, treatment by injection is bound to fail.

I wish to recite in detail an example of this. A patient presented herself for treatment with a large left labial hernia. She was given a course of twelve treatments, and apparently a very firm proliferation in the inguinal canal was produced. Two months later she returned with a definite bulging and impulse on coughing, but smaller than previously. She was again given a series of twelve treatments. By this time the induration was almost cartilaginous in feeling. After several months, and wearing her truss all the time, she appeared at the clinic. To our chagrin we found that a small hernia was still evident. She was very much opposed to the suggestion of operation, and for the third time we attempted to close the canal by injections. She received thirty-six injections altogether, without being able to close the hernial sac. She finally submitted to operation, and at that time it was found that the fascia of the external oblique was densely adherent to the underlying muscles. A large markedly thickened sac was dissected free. When opened and the neck of the sac examined, the cause of our failure was evident. Surrounding three-quarters of the circumference of the neck of the sac was a firm mass of fat about the thickness of the end of one's thumb. This prevented the proper closure of the internal ring and obliteration of the sac. Biopsies were taken from the muscle and fascia. The muscles were then sutured to Poupart's ligament. The density of the muscles and Poupart's ligament was astounding, it being with considerable difficulty that the needle could be introduced.

Autopsy Report.—Microscopic sections of the tissue removed showed a most interesting condition. The report of Dr. A. M. Moody, pathologist, was as follows:

> The scar tissue which has developed in sections of injected hernia examined in the pathological laboratory of the Southern Pacific General Hospital is very dense, relatively thick and markedly hyalinized. This condition has occurred with a minimum of cellular reaction.

NUMBER OF TREATMENTS MAY VARY

While on this subject of the number of treatments to be given an individual case, it is impossible to state definitely that ten to twelve, or even fifteen treatments, will be sufficient. What might seem to be a perfect closure at the completion of the treatment may several months later show some resorption, and several more injections would be indicated. If a patient returns from six to eight months after completion of the treatment, and the tissues are not as firm as formerly, and there is a definite weakening, I do not believe this should be considered a recurrence, but rather a case of undertreatment. One of the great advantages of this treatment is the fact that a recurrence can be prevented by a few more injections. Whereas, following an operation, the same condition would become a definite recurrence, requiring a second operation, which is always more dangerous and more unsatisfactory than the original one.

The number of treatments necessary must be determined by the size of the hernial defect, the response of the tissues to the injected solution, and the amount of resorption which takes place after the first course of treatment has been given. I believe that the treatment should be considered in two stages. The first stage is the original course. The second stage is the period of observation, lasting from one to one and one-half years. Patients should be carefully examined every two months after the truss has been removed. If an area is found which shows evidence of weakening, a few more injections should be given. Not until the patient has been under observation for from one year to eighteen months can one feel sure that a permanent cure has been obtained.

We have found in our series of 190 cases who presented themselves for treatment that twenty-two, or approximately 11½ per cent, were recurrences following herniotomy. I believe that with the combined technique of operation and injections, if recurrence is threatened, that the necessity for operating on a patient the second time for hernia will be eliminated.

COMPLICATIONS

Many complications have been mentioned as likely to be the result of the injection treatment, none of which in our series of 190 hernias treated and under treatment at present, have we encountered. Infection, abscess formation, peritonitis, atrophy of the testicle, and sterility, have all been noted as possibilities. The one most common complication we have had has been moderate swelling of the cord, which lasts from a few days to several weeks, but which always subsides, leaving no evidence of permanent damage. A few patients have complained of swelling of the testicle for seldom more than twenty-four hours. One must be particularly careful when injecting in the region of the internal ring because of the proximity of the anterior crural nerve and the femoral vessels. I make it a point when injecting this area to tell the patient to notify me immediately if there is any painful sensation running down the anterior surface of the thigh toward the knee. This happened in two of the earlier cases, but with no permanently bad result.

HERNIAS TREATED BY INJECTION METHOD AT THE SOUTHERN PACIFIC HOSPITAL

The injection treatment of hernia was first begun at the Southern Pacific General Hospital in July, 1934. At the time this paper was written a total of 190 cases had been treated or were under treatment. There were 140 indirect inguinal hernias, 21 direct, 4 scrotal, and 22 recurrent, following herniotomy; also two femoral and one umbilical. Out of this series we had only one definite failure, which required operation. Eighteen patients have required further treatment because of weakening of the canal due to complicating diseases, such as vomiting and loss of weight due to peptic ulcer, severe spasmodic coughing (associated with tuberculosis and asthma), influenza, and the improper wearing of the truss.

COÖPERATION OF PATIENT WITH SURGEON IMPERATIVE

I know of no type of treatment in which the coöperation of the patient with the surgeon is more imperative, especially regarding the wearing of the truss properly for the required length of time. The majority of our patients are rather ignorant laborers, and it is difficult to make them understand the importance that a properly placed and well-fitting truss has on the final result.

POSSIBLE CONTRAINDICATIONS

Considerable judgment must be used in accepting patients for treatment who are suffering from peptic ulcer, arrested tuberculosis, asthma, etc. They often appear to be in good physical condition and well-suited for the treatment. After the treatment is finished they may develop severe symptoms from their complicating disease, which will have an unfavorable reaction on the hernia recently treated. I speak feelingly on this subject, because I have recently examined two patients who apparently had a very satisfactory closure of their inguinal canal, but one man developed a very severe ulcer attack, with severe vomiting, hemorrhage, and loss of nearly forty pounds in weight. During the attack he removed his truss, and when he appeared at the clinic some months later his truss was absolutely useless, being now entirely too large, giving no support to the inguinal canal. Consequently, there was a small return of his direct hernia. The other patient returned fourteen months after the finishing of his treatment, with a small bulging at the external ring of one week's duration. He stated that for years he had been receiving 50 per cent disability compensation from the Government for arrested tuberculosis, associated with asthma, and that he had frequent violent coughing attacks, so severe as to cause emesis.

I cite these cases to show that while some patients may appear to be in good physical condition, histories should be very carefully taken to determine if any condition is present which might contraindicate the injection treatment.

RESULTS NOTED IN A POSTOPERATIVE SURVEY

Recently all patients who had received treatment longer than six months ago were requested to report for examination, or to have their company doctor examine them if they lived some distance from San Francisco. Questionnaires were sent out to 106 patients having 114 hernias, there being eight with double hernias. To date, those who have responded show a very satisfactory closure of the canal. Out of this number, seven will require further treatment, and two of the seven have developed tuberculosis, with consequent weakening of the inguinal region from excessive coughing and loss of weight. Of all the patients treated to date, eighteen have required further treatment. In a large percentage of these cases that would not have been necessary had we received intelligent coöperation from them. It is most gratifying to note the interest being taken in this method of treating hernia by the more conservative surgeons, medical schools and clinics, who several years ago showed little interest in it.

MORE STUDY NEEDED IN THIS WORK

Those of us who are pioneering this work should give every aid to others wishing to test this treatment seriously, and in a thorough scientific manner. I feel sure that every surgeon using this method on a large number of patients will have something constructive to offer from his observations. With the right men and institutions using it, a great deal of the prejudices against this treatment will be removed. Much experimental work must yet be done in the matter of solutions, number of treatments required, and in judging the type of hernia suitable for this treatment. By that I mean whether it should be confined, as some men think, to small indirect, incomplete hernias, or should treatment of all types of reducible hernia be attempted. Refinements in technique and the various types of trusses to be used must also come in for serious consideration.

We are looking forward to the time, in the not too distant future, when the surgeon will find in this method of treating hernia, a most valuable aid to the operative treatment, especially when used after operation, to strengthen a postoperative weakening of the canal, thereby practically eliminating the need for reoperating a hernia.

ECONOMIC VALUE OF INJECTION TREATMENT IN HERNIA

The present costs of the surgical treatment of hernia must be divided into two groups:

1. Compensation costs, being direct compensation for disability and time, or wage losses.
2. Medical costs for surgical fees, hospitalization, etc.

The most complete figures that I could obtain came from the Division of Statistics and Information, New York State Department of Labor. From 1930 to 1934, inclusive, 20,765 cases received compensation, amounting to $4,526,436, at the average cost of $217 per case for compensation. This compensation was for temporary total disability and was estimated at the rate of two-thirds of the wage rate. A general estimate, however, indicates that the total compensation paid to employees has averaged only 40 per cent of their wages, leaving an uncompensated loss in wages through disability of 60 per cent, or $323 per case, to the employees themselves. This must be counted into the aggregated cost of the surgical treatment even though the insurance carriers do not pay it.

Regarding medical costs, inquiry was made of three of the largest insurance companies' executives, statisticians, etc., and the consensus of their estimates is $170 per case for medical and hospital services. To this should be added $323, which is the uncompensated wage lost to the incapacitated employee.

The above figures were from the Division of Statistics, New York State Department of Labor, and from an article by F. E. Rutledge in the *Eastern Underwriter,* November 2, 1934.

Many states do not pay compensation for hernia cases, which means that the entire loss of wages from disability falls upon the wage-earner. In California, compensation is not paid for disability due to hernia, but an average of $150 per case is paid for medical and hospital care.

In analyzing five hundred histories of operations for hernia at the Southern Pacific General Hospital, I found that the average time in the hospital was nineteen and one-half days, and the average length of disability was forty-six days. A very conservative estimate shows the cost of hospitalization and loss of wages per case to be approximately $315. When using the injection treatment for hernia, there is no hospitalization and no compensation to be paid for disability. There is no loss in wages to be borne by the employee. The only costs are for the truss and the fee to the surgeon giving the treatment. The Industrial Commissions of two states, namely, Minnesota and Arizona, already recognize the injection treatment of hernia, and pay a fee of $50 per patient for the treatment.

The following is quoted from a letter to me from the Industrial Commission of Minnesota: "This commission recognizes the injection treatment of hernia, and the fact is that nearly all hernias are now treated by this method. When an employee sustains a compensable hernia and is treated by the injection method, the employer and insurer pay for the truss, which is worn while the treatments are being given, and pay the doctor for the treatments. There is no compensation for such cases, as there usually is no disability."

If figures for the entire country could be obtained to show the amount paid per year in the United States by insurance carriers for compensation and surgical treatment of hernia, the amount would run into millions of dollars. Add to this the uncompensated loss in wages to the employees and the costs of surgical fees and hospitalization for the treatment of hernia in private patients, which naturally would be much higher, and the total sum would be astounding. It is not difficult to estimate the tremendous savings to be made both in time and money when the injection treatment of hernia is more universally adopted.

CONCLUSIONS

1. A rational method of curing certain types of hernia is offered by the injection method.
2. It should be used only by men surgically trained, with a knowledge of the anatomy and pathology of the inguinal region, and an accurate diagnostic ability.
3. The method is safe when used by the experienced operator, but there are potential dangers when used by men with little knowledge of the exacting technique and of hernia in general.
4. The numerous complications mentioned are mostly theoretical, and have not occurred in this series of 190 hernias.
5. Many patients who are poor subjects for operation may be treated by this method and rehabilitated to useful occupations.
6. The value of the operative treatment of hernia can be greatly enhanced by the use of injections when a postoperative weakening is threatened or a recurrence develops.
7. Economically, there is a great saving of time and expense, because there is no loss of time from work, and no hospitalization is required.
8. The wearing of a properly fitting truss for at least six months after treatment is most essential.
9. A careful check-up every two months for eighteen months following the completion of the treatment should be made, and a few reënforceing

treatments given when signs of weakening are discovered.

10. The investigation of this method by hospitals and clinics where large numbers of hernias are treated would aid greatly to give this treatment the same dignity and standing as operative procedure.

11. Records of all patients treated should be kept for years, to determine the permanency of the cure by injection. Only by so doing can the true value of this treatment be estimated in terms of the results obtained by the operative treatment of hernia. If the results, say in ten years, prove to be only as good as those in the surgical treatment, at least a great economic saving would have been accomplished, and many patients who now refuse operation, or who are not physically fit to be operated upon, would be saved the danger and discomfort of an untreated hernia.

INJECTION TREATMENT OF HERNIA: ITS PRESENT-DAY STATUS*

By Franklin I. Harris, M.D.
and
Alfred S. White, M.D.
San Francisco

Discussion *by Charles Eaton Phillips, M.D., Los Angeles; Francis M. Findlay, M.D., Santa Barbara; Leonard Dobson, M.D., San Francisco; E. Eric Larson, M.D., Los Angeles; Alanson Weeks, M.D., and G. D. Delprat, M.D., San Francisco; Donald C. Collins, M.D., Los Angeles; W. L. Weber, M.D., Los Angeles.* (The discussion refers to this and two preceding papers on the Injection Treatment of Hernia.)

THIS method of treatment of hernia, the basis of which has been established today on experimental laboratory findings, is possible in patients of all ages. With the present extent of the knowledge of this subject, however, it is advisable to limit its use to adults. The prime requisite is that the patient has a completely reducible hernia which can be maintained in complete reduction at all times during the course of active treatment by a properly fitting truss.

Cases of direct and indirect inguinal, and recurrent inguinal herniae, are the most suitable for this method of treatment. Although umbilical, femoral, and incisional herniae have been successfully treated by this method, it is best at this time to limit the discussion of its use to the inguinal varieties.[1]

Chronic bronchitis and cardiac disease are no contraindication to the injection treatment.

APPLICATION OF TRUSS

The first and most important consideration in the actual treatment of any given case is the application of a truss. The hernia must not only be reducible, but it must be one which can be held completely reduced at all times regardless of the activity of the patient. The selection of the truss is of the utmost importance, for herein often depends the success or failure of the treatment. The prerequisites, described in the previous paper, in the construction of the truss must be remembered. Such a truss must be worn day and night during the course of injection, and for a four-week period thereafter. Depending on the physical activity of the patient, it must be further worn during the day for an additional four- to six-month period. It is, therefore, imperative that reasonable comfort be provided in the fitting of the truss. It must be made of waterproof material, as the patient keeps it on during his shower. When the patient is fitted with a truss that is satisfactory, he is instructed to wear it day and night for a period of one week; and if it is uncomfortable, or if the hernia is not held completely reduced, adjustments are made as necessary. Occasionally, in patients who have never worn a truss before there is considerable irritation of the skin, and it may be necessary to discontinue wearing it for a few days. Before beginning the treatment, however, every difficulty involved in the fitting and wearing must be adjusted. This may take from one to three weeks, but such time is well spent, as it assures the success of the subsequent treatment. Once the treatment is begun, the truss is never removed, except by the physician for the purpose of treatment.

PROCEDURE IN TREATMENT

The treatment is begun with the patient placed on a surgical table in Trendelenburg position and the truss removed by the physician. It has been found unnecessary to remove the truss entirely, as it can be slipped down over the thighs while the patient aids by slightly lifting the buttocks. With the truss removed and the patient in this position, the hernia is found to be completely reduced. The hair over the inguinal region is clipped and cleansed with alcohol, then painted with iodin solution or tincture of merthiolate, after which the patient is ready for the injection of the proliferating solution. A suitable local anesthetic is given preliminary to the injection of the solution. A local anesthetic of novocain 2 per cent is satisfactory, but a combination of novocain 2 per cent, nupercain 1:1000, and benzyl alcohol 2 per cent in distilled water gives a more prolonged effect. If Sylasol is used, no local anesthetic is necessary, since it is not painful when injected into tissues.

Needles.—The choice of a needle depends on the distance between the skin and the inguinal canal. This varies with individual patients and with the thickness of the abdominal wall. In thin persons, a needle 1 to 1¼ inches is satisfactory, while in more obese patients needles of 1½ to 2½ inches may be required. Generally speaking, the smallest gauge commensurate with the length is the most satisfactory. With the proper-size needle determined, it is fitted to a five cubic centimeter Luer syringe and then filled with the anesthetic.

TECHNIQUE

The syringe is loaded with four cubic centimeters of the local anesthetic, and the injection is given with the operator standing on the left side

* From the Department of Surgery, Mount Zion Hospital, San Francisco. Service of Dr. Harold Brunn.

Read before the General Surgery Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

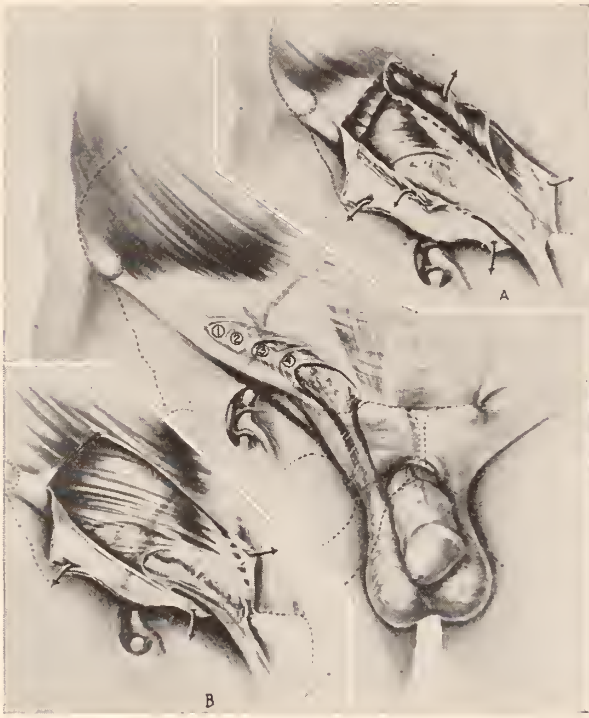

Fig. 1

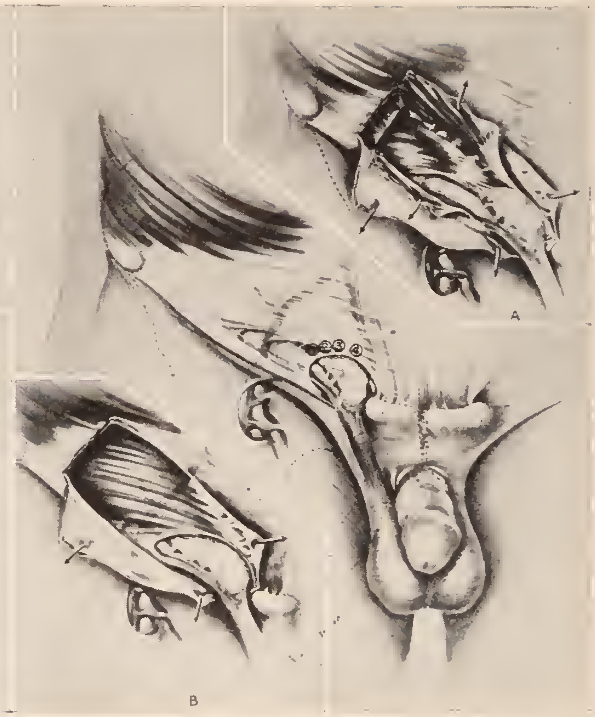

Fig. 2

Fig. 1.—Diagram to show points of injection in indirect inguinal hernia. Note that the first injections are given over the internal ring and subsequent injections placed down the canal. Two to four injections are given at each of the figured points.

Fig. 2.—Diagram to show points of injection for a direct inguinal hernia. Note that the injections are given over Hesselbach's triangle. Two to four injections are given at each of the figured points.

of the patient. Regardless of whether the hernia is on the right or left side, this position is most satisfactory for right-handed operators. The index finger of the left hand is then placed into the external ring by invaginating the scrotum. The tip of the invaginating finger can be palpated by the right hand. With the tip of this finger as a guide to the direction of the inguinal canal, the internal ring is located one centimeter above the inguinal ligament, and midway between the anterior superior spine and the pubic spine. The needle with the Luer attached is then inserted through the skin, fat, and through the external oblique muscle. No skin bleb of anesthetic is used, since the injection of the needle through the skin is no more painful than the injection of the bleb. As the needle passes through the external oblique there is a definite "give," similar to the one experienced in passing a needle into the spinal canal. This will be more marked if the needle used has a blunt bevel. The needle within the inguinal canal can often be readily palpated by the index finger of the left hand, which is invaginated through the scrotum into the canal. The plunger of the Luer is then withdrawn slightly to make sure that a blood vessel has not been entered, and if no blood is withdrawn the anesthetic is slowly injected. Following the injection the Luer is removed from the needle, but the needle is left in place. This is done so that the anesthetized area will correspond exactly to the area which will be injected shortly by the proliferating solution. If the needle is removed and a second needle injected with the solution after the anesthetic has taken effect, it is difficult to get the exact layer of anesthetized tissue. The projecting hub of the needle is then covered with a sterile gauze pad, and the patient cautioned neither to move nor cough.

A ten-minute period is then allowed to elapse in order to give time for the local anesthetic to take effect. The Luer is then filled with three cubic centimeters of the proliferating solution attached to the needle, and the solution is slowly injected. The needle is removed and the patient allowed to remain in the Trendelenburg position for a period of ten minutes, following which the truss is reapplied by the physician, and the patient can get up from the table.

SUBSEQUENT INJECTIONS

Subsequent injections are given every other day, and all except the first injection are of four cubic centimeters of the proliferating solution. In all injections following the initial one, the amount of anesthetic used is five cubic centimeters. In other words, the amount of local anesthetic used should be one cubic centimeter greater than the amount of proliferating solution injected. The dose of Sylasol is three cubic centimeters for each injection.

Subsequent injections are given in the region of the internal ring until that area is filled with plastic exudate; these are usually three to five injections. Further injections are given down the inguinal canal toward the external ring. In the case of a direct hernia the injections are given in the region of Hesselbach's triangle. (Figs. 1 and 2.)

After a few injections it is hard to identify the external ring, and a hard rubber-like mass is felt, occupying the greater part of the inguinal canal. If injections are now continued into this area, it feels as if the needle is being inserted into rubber. After a few injections one sometimes notices, on aspirating following the injection of the preliminary novocain, the return of a yellowish, murky fluid. This should not be mistaken for either bladder contents or peritoneal fluid. It represents the mixture of the anesthetic agent with the edematous exudate in the inguinal canal, and injections may be continued into such a region. Injections are given until the inguinal canal and the region of Hesselbach's triangle are entirely closed.

The number of injections in any given case depend on two factors, the size of the hernia and the seroplastic reaction of the individual. As a general rule, in elderly patients there is less seroplastic reaction, consequently more injections are required. A graphic record is kept of the injections given to each patient.

After the last injection the patient continues to wear the truss day and night for a period of four weeks to allow the newly formed fibroblastic tissue to increase in strength. At this stage of the treatment any descent of the contents of the sac would cause distention of the inguinal canal and a tearing and destruction of the newly formed fibroblastic tissue. Following this four-week period, it is advisable to wear the truss during the day only for an additional period of four to six months.

FOUR PHASES OF TREATMENT

A description of the complete course of treatment divides itself into four phases:

1. The preliminary treatment, consisting of eight to twelve injections as just described, given three times a week, usually closing the hernia.

2. The reinforcing treatment, consisting of one injection a week for four weeks. The location of these injections is determined by the judgment of the operator.

3. Period of immediate follow-up during which the patient is examined once a month for six months, and if there is any evidence of weakness an occasional reinforcing injection is given.

4. Final follow-up period, extending over a period of one year. The patient is seen at intervals of two months for check-up examination.

COMPLICATIONS

Complications during the course of treatment are surprisingly small. Patients not infrequently complain of curious transient subjective sensations, such as burning in the scrotum or penis, on the inner side of the thigh, or a sensation of warmth around the anus. These painful sensations are due to involvement of the ilio-inguinal nerve and its branches. By slight movement of the injecting needle when such sensations appear, this type of pain may be minimized. Occasionally, a few seconds after an injection in the neighborhood of the internal ring there may be a feeling of cramp in the distribution of the anterior crural nerve. Following the first or second injection, there may be some swelling and induration of the inguinal canal or of the cord, the skin of the scrotum or the epididymis. This may be painful, but it has never kept a patient from his routine duty and quickly responds to local applications of heat. Such complication is due to temporary obstruction of the spermatic circulation from the edematous reaction produced by the solution. However, there has been no case of permanent damage or any atrophy of the testicle. If while giving an injection the needle inadvertently enters a blood vessel, it is withdrawn and no injection is given that day. This has occurred about once in every seventy-five injections in our series. Rarely the needle is injected into the peritoneal cavity, and in our series it has only occurred eight times in about three thousand injections. If the proliferating solution is injected into the peritoneum, the patient complains of extremely severe cramp-like pain which gradually subsides in ten to twenty minutes, depending on the amount of solution injected. No untoward results have been seen clinically, nor have they appeared, as outlined above, experimentally from this accident. In order to minimize these accidents the injection of the proliferating solution should be given *very slowly*, and at the first complaint of colicky pain the injection is discontinued.

CONTRAINDICATIONS AND DANGERS

No case of irreducible, incarcerated, strangulated or sliding hernia or hernia associated with undescended testicle can be considered suitable for treatment by this method. The danger of perforating the bowel in such cases with a production of fecal fistulae and peritonitis is obvious. Even in the reducible herniae the peritoneal cavity may be occasionally entered through an error in technique and, although there is no danger to life by such a mistake, the patient experiences pain sufficient to produce a state of shock. To minimize such a dangerous complication, emphasis cannot be placed too strongly on the necessity of injecting the proliferating solution slowly and cautiously. In this respect the alcoholic solutions of tannic acid appear somewhat safer, as they produce an instantaneous peritoneal reaction which can be minimized by stopping the injection. A non-alcoholic solution such as Sylasol has a latent period of pain production, so that if the peritoneal cavity is entered the full dose will inadvertently be given. The shock resulting from such a procedure will not become apparent for five to ten minutes.

Hemophilia is a contraindication to this procedure as it is for any treatment which requires repeated punctures with a needle. Chronic urinary retention in elderly men increases the danger of bladder injury, and unless one is thoroughly experienced such cases should not be attempted.

It is a general surgical principle that injections of any type should not be given in the face of apparent superficial skin infection, and the indiscriminate use of this method of treatment in patients suffering from any type of infection in the area to be injected must result in disaster. Diabetics are best not treated because of their increased susceptibility to local infection.

Table 1.—*Statistical Table Results of Injection of Hernia to May, 1936*

Total Number of Cases: 165	Completed Cases	Patients Under Treatment	Total
Inguinal—Good surgical risks (direct and indirect) ...... (Average age 37)	73	66	139
Inguinal—Poor surgical risks direct and indirect) ...... (Average age 68)	23	3	26
			165

Cases in which the intelligent coöperation of the patient cannot be absolutely assured are best advised against this treatment. The inconvenience of wearing a truss continuously day and night for a period of six weeks to two months should be thoroughly explained to the patient, and unless a promise of obedience to this rule is obtained there is danger of complete failure of the treatment. A partially completed treatment in such a case may increase the danger of strangulation in that particular hernia. Highly nervous or apprehensive individuals, cases of hyperthyroidism and children are not good subjects in general for any form of local injection treatment, and are better treated by the recognized surgical procedures.

Especially dangerous is the use of solutions which have not been proved by experimental and clinical results to be suitable for the treatment of hernia by injection. The type of solution used in the treatment of varicose veins is absolutely contraindicated, as it works on an entirely different principle.

RESULTS

Since this work was started in the outpatient department of the Mount Zion Hospital early in 1934, one hundred and sixty-five cases of inguinal hernia, both direct and indirect, have been treated. The entire number of injections given has been well over three thousand. Although it is too early to state definitely that the results are equal or even better than those treated by surgery, we can say that at the completion of treatment in all these cases, and in the follow-up period available up to this date (May, 1936), the results from both the patients and the surgeons' standpoint have been eminently satisfactory. Bratrud,[2] Mayer, and Fowler in this country, Gray in England, and Wyss in Switzerland, have reported many thousands of cases with longer follow-ups, and their results have been very favorable; these authors claim a recurrence of only from 2 to 10 per cent.

For a statistical analysis we have divided our cases into two groups which have been designated as, first, the operative group or that group which would ordinarily be classed as a good operative risk; and, second, a non-operative group, including such patients who, for one reason or another, are poor surgical risks. In the first group our statistics show that the number of recurrences and the ease of cure compares most favorably with operative statistics, in fact our recurrence rate being about 4 per cent. In the second group the recurrence rate is about 22 per cent. (Tables 1 and 2.)

COMMENT

Recurrences.—Recently W. B. Coley, in the *American Journal of Surgery,* wrote an editorial on hernia and discussed the experience of workers at the Ruptured and Crippled Hospital in New York with the injection method.[3] He made the bare statement that "first the results seemed very satisfactory, but by the end of six months there were so many recurrences that the method was definitely abandoned." Such a statement is naturally extremely disquieting, but as no details are furnished regarding the technique of treatment it is impossible to critically analyze or explain his conclusions, in the light of our experience, which we are reporting today.

Our own figures show a recurrence rate at this time of about 4 per cent in a group of patients who would have been excellent risks for a surgical repair. Such a figure certainly is no worse than the expected recurrence rate following operation. We further believe that with greater experience in this method of treatment our recurrence rate in this group will be definitely decreased.[4]

A re-definition of the word "recurrence" must be found, as we apply it to a discussion of cases treated by the injection method. If a weakness appears at the site of the hernia following treatment by the injection method, we can more properly say that this case is one in which there has been insufficient treatment. If such a weakness does occur, a few additional injections will close the hernia. It is not a recurrence in the surgical sense of the word, but rather insufficient treatment. If we find, for example, that those cases which have had six or eight injections show weakness in the course of a few months following treatment, it may be necessary to increase the number of initial injections to ten, twelve, or even fifteen, as a routine procedure. The greater our experience has been, the more convinced we become of the importance of subsequent injections following the apparently complete closure of the hernia. If despite an indefinite number of injections the weakness still persists, these cases are the ones that we can classify as recurrences.

Regarding that group of patients whose average age is sixty-eight and who were suffering in

Table 2.—*Recurrences*

(All cases with from 6 to 18 months follow-up after completion of treatment)

	Inguinal Good Surgical Risk	Inguinal Poor Surgical Risk
Number of cases	73	23
Number of recurrences....	3	5
Percentage of recurrences	4.1%	21.7%

many cases from advanced forms of heart disease, chronic bronchitis and general senile debility, and whom we have placed in a group called nonoperative cases, we consider our recurrence rate of 22 per cent very satisfactory. One must remember that 78 per cent of this group were cured of their hernia, while surgery offered none of these patients the possibility of relief. Furthermore, of the 22 per cent we have classified as recurrences every patient has shown some degree of improvement either in marked diminution of the size of the rupture or improvement to the point where a truss could be fitted to satisfactorily maintain the hernia and eliminate the discomforts of a completely uncontrolled rupture.

Mortality.—There is no mortality attributable to the injection method as used today. Reports of mortality appearing in the literature from 1840 to 1910 followed the injection of phenol iodin, etc., and do not in any sense apply to the modern method. The dangers of postoperative pneumonia, embolus, and the other complications following the surgical treatment of hernia are familiar to all of us. It is significant that not once in the modern literature does there appear a record of similar complications following the injection method.

Applicability to Recurrent Hernias.—The method is particularly valuable in cases of recurrent hernia. Such cases are the bane of the surgeon. An operator should welcome a method which offers the possibilities of successfully treating their recurrent herniae without recourse to surgical intervention. The results obtained by the injection treatment in this group of cases have been, in our experience, particularly gratifying.

The treatment is entirely ambulatory. The advantage of the lessened cost, due to elimination of hospitalization and loss of work, is obvious.

SUMMARY AND CONCLUSIONS

1. The injection treatment of hernia is applicable to all cases of reducible inguinal hernia.

2. An exacting technique is described which involves:

(*a*) The use of proved solutions.

(*b*) Knowledge on the part of the surgeon of the anatomy of the inguinal region as well as the proper fitting of a truss.

(*c*) A period of treatment and observation extending over eighteen to twenty months.

3. There have been no untoward complications, no atrophy of the testicle, no impotence, no deaths in a series of 165 cases.

4. A recurrence rate of 4 per cent is reported by this method of treatment when used in young, good risk individuals; and of 22 per cent in a group of elderly, poor risk patients.

5. The method of treatment can be expected to give better results than reported, as more knowledge and greater experience is obtained by surgeons using it.

DISCUSSION*

Charles Eaton Phillips, M. D., (1919 Wilshire Boulevard, Los Angeles).—The history of the injection treatment of hernia seems to have originated with George Heaton in the year 1832. Whether he was a physician or a charlatan is not apparent. His claims to a 100 per cent cures might be considered an evidence of irregularity! Before the days of anesthesia his method had much to recommend it.

Since the advent of anesthesia it has been exploited by the quacks who have popularized the treatment with the slogan, "Hernia cured without the knife."

The fact that a simple obliteration of the sac by any means is said to cure from 70 to 80 per cent of hernias renders "experience fallacious and judgment difficult."

Hernia operations consisted of little more than a resection of the sac up to the time of Bassini who, in 1885 (published in 1888), showed that the most important consideration in the cure of hernia was in the restoration of the musculature over the defect. Hernias which healed by the formation of scar tissue were liable to recurrences in 20 to 30 per cent of cases, while restoration of the musculature of the canal resulted in a cure in 95 to 98 per cent of cases.

Anyone who has had extensive experience in the closure of abdominal wounds knows that the presence of scar tissue jeopardizes the result. The utilization of scar tissue in the closure of a defect invites almost certain subsequent rupture. While the recurrence may be delayed until there is a natural atrophy affecting the scar tissue, the certainty of recurrence varies with the amount of scar in its closure. The injection treatment claims to cure the hernia by scar formation.

Safety.—No one has the diagnostic acumen to tell accurately what is contained in the hernial sac. A small diverticulum of the bladder or adherent intestine or appendix at the internal ring cannot be determined by the most careful physical examination. A solution which is innocuous when injected into the peritoneal cavity or into a vein may cause necrosis of the bowel when injected into its wall. The same can happen when the injection is inadvertently made into a bladder diverticulum. The probability of injury to the vas and sterilization by injection should not be overlooked.

These are not theories. They are things actually happening following the injection treatment of hernias. The writer has been informed, on good authority, that three fatal cases have been admitted to one hospital within the past few weeks. The injections penetrated the wall of an adherent cecum with subsequent perforation, peritonitis and death.

If the treatment is actuated by the effort to save someone money, why not save the cost of the injection and let the patient continue to wear his truss?

The conclusions of such an authority as W. B. Coley and associates in the Ruptured and Crippled Hospital in New York, who have tried the method and have abandoned it, should not be taken lightly.

⁂

Francis M. Findlay, M. D. (1515 State Street, Santa Barbara).—The papers of Doctors Girard, Harris, and White should be studied by every physician who contemplates using the injection method for treatment of hernia. The historical background and experimental evidence that support this form of therapy have been admirably summarized by them. These men have given us their clinical results in a frank, impartial manner. We are, therefore, indebted to them and to their colleagues, who are working in other medical schools and clinics, for the scientific, orderly presentation of a problem formerly handled by the charlatans and quacks.

---

* A discussion on papers of Dr. F. R. Girard, page 385, and Drs. F. I. Harris and A. S. White, pages 382 and 391.

I am especially glad that the papers presented today have stressed the necessity for careful observation of clinical results and a further study of the problem. Reporting of bad as well as good results is essential if we are properly to evaluate any method of treatment. Only by combined efforts along these lines will we ascertain the truth. Success in this field demands a sound surgical training and complete knowledge of the anatomy of the inguinal region.

The injection treatment for hernia is now very popular with many doctors in this country, especially in California. Even the most skeptical must admit that, in the majority of cases, firm scar tissue forms and closes the hernia. There is, however, considerable, justifiable doubt in the minds of many sane, experienced surgeons as to the permanency of these results. Such observers rightly question that the fibrous tissue resulting from these proliferative solutions is the equivalent of living fascial grafts in the repair of a weakened abdominal wall. Time alone will tell whether the injection form of treatment will constantly give permanent results and eventually replace operation in the majority of cases.

The speakers have stressed some of the definite dangers inherent in this form of therapy. I wish to reëmphasize that this procedure is not free of risk, and to add a warning concerning the possibility of gas-gangrene infection in these cases.

In their enthusiasm for this nonoperative treatment some men fail to realize that there are definite inherent dangers in the procedure. The injection treatment of hernia is still somewhat of a blind procedure, for it is impossible to visualize the hernial sac and its contents, or to determine accurately its extent. Although the hernia may apparently be reduced, there is always a distinct possibility of a piece of omentum or intestine being caught in the inguinal canal, or adherent at the internal inguinal ring. An adherent loop of bowel can easily be punctured by the injecting needle and infection result.

I add this warning concerning the dangers of injection because of the recent occurrence of a fatal case of gas-bacillus infection which followed the injection treatment of hernia. This patient, a 75-year-old diabetic, had been treated in another city by a physician with considerable experience in the injection method, and he was given four routine injections of four cubic centimeters each of Pina Mestre solution at three-day intervals, without incident. But three days after the last injection the patient became ill and his diabetes grew worse. He did not improve at home, so two weeks after the last injection he entered the hospital. On admission he complained of pain in his groin and lower abdomen, with stiffness of his thigh muscles. Motion of the hip was painful, and the patient continued to run a septic temperature, at times being irrational. Although no localizing signs of pus could be found around the hip on admission, the thigh was swollen. On the twelfth day the patient's temperature rose to 104 degrees, and a distinct crepitation in the tissues around the hip was first observed. That afternoon the patient went into collapse, from which he failed to recover, dying on the fourteenth day.

Autopsy disclosed extensive gangrene of the right iliopsoas muscle, extending down into the thigh, apparently originating at the internal inguinal ring. The tissue had the characteristic appearance and odor of gas-bacillus infection. The anaerobic Bacillus welchii was recovered from the muscle tissue and identified both by smear and culture, removing all doubt as to the causative agent. Further examination disclosed a loop of small intestine adherent to the inguinal ring that apparently had been punctured by the injecting needle, causing leakage of intestinal content with the fatal gas-producing organisms.

Every physician should know that puncture of the bowel may occur during the injection treatment of hernia. If leakage of intestinal content occurs, a virulent anaerobic infection that is usually fatal may result. Although these papers today have shown that the injection treatment of hernia is now being studied in a scientific manner, we must remember that this form of therapy is not entirely free of risk.

Leonard Dobson, M. D. (Stanford Hospital, San Francisco).—At first I was prejudiced against the injection treatment of hernia. Before I was familiar with the technique I felt it was a blind procedure, frequently accompanied by serious complications and productive of doubtful end-results. As Doctors Girard, Harris, and White have shown in their papers, that opinion was fully justified until several years ago, when carefully conducted experimental work produced safe, effective solutions and a satisfactory technique. Before adopting a new procedure the medical profession wants to know the end-results, and carefully controlled follow-up series have only recently been reported.

I became interested in this treatment by observing in Doctor Girard's hernia clinic. I desired to determine the effects in the tissues of the various solutions used, so before starting to use the treatment, I conducted a series of animal experiments in the Stanford surgical laboratory. The rectus muscles of dogs were injected with three of the most commonly used solutions (phenol and thuja mixture, proliferal, and sylasol). Tissue was removed from the injected areas at various intervals from one to one hundred and twenty days and examined microscopically. The reaction of the tissues to the various solutions was very similar and paralleled the results obtained by Doctors Harris and White in guinea pigs, except that the early polymorphonuclear response was not as intense.

Since starting the injection treatment in the Stanford surgical clinic nine months ago, we have had no complications. Sylasol has been the solution used. The cases have been under observation too short a time to report end-results, but no recurrences have been noted to date. We have used the treatment in both direct and indirect inguinal hernias.

I agree that this method of treatment should only be employed by surgeons thoroughly familiar with the anatomy of the inguinal and femoral regions, and feel that the best results will be obtained by those who have injected a large number of cases. I feel that the method will not supplant surgery in the treatment of hernia, but is a highly successful adjunct in selected cases.

⁂

E. Eric Larson, M. D. (1930 Wilshire Boulevard, Los Angeles).—Surgical repair of herniae has been improved to such an extent that most any well-qualified surgeon can offer to his patient an excellent prospect of cure. It is difficult to counteract this with new ideas and methods.

Since compensation insurance is universal, and herniae are general among humans, it is quite logical that both the insurance carriers and the layman are willing to try a new method for cure when time and finances may be of prime importance.

In spite of conflicting reports over a large series of cases, the more recent injection method must be thoroughly investigated and the results tabulated over a long period of time.

The authors of these papers have made a distinct contribution to the literature on the subject. The animal experimentation toward the cellular pathology caused by the different solutions is noteworthy. Their tabulated series of patients so treated are interesting, and certainly merit close study and comparison with the surgical repair.

The safeguards mentioned by the authors are made for the best interest of the patients and the method of treatment, and should be carefully considered. The subject is still quite controversial and complications can end in disaster for the patient.

Careful selection of coöperative patients to those with reducible herniae, securely held by a spring truss and treated by well-qualified surgeons who know the anatomy and complications that can easily occur, is stressed by the authors.

Certainly poor risks for surgical repair such as the aged and those with chronic ailments, such as diabetes and tuberculosis, and even those patients with an enlarged ring conducive to a potential hernia, should have the advantage of the injection treatment. Recurrences of minor proportions can also be treated with efficiency by injections.

I have had the opportunity of examining many such individuals with excellent results after this treatment. Attention has recently been called to the danger of truss pressure to the cord when there is a scar tissue surrounding this structure. Refinements in technique and elaboration of the best solution to be used, as well as after-care, have not been fully worked out. Such papers as these will add a great deal in perfecting the scarifying method for treating reducible hernia. I am sure nearly all of us agree it has already established a place in our method of treating herniae.

⁂

Alanson Weeks, M.D., and G. D. Delprat, M. D. (384 Post Street, San Francisco).—Doctor Girard, and Doctors Harris and White present a very careful and clear discussion of the subject, "Treatment of Hernia by the Injection Method," and it is perhaps presumptuous for those who have not used this method of treatment to discuss their papers.

The authors describe the fluids used for injection and state that their action is due to the production of an exudate and later fibrous tissue development between the layers of the muscles of the inguinal canal. The rationale of the treatment is based upon the fact that after an inguinal hernia is reduced, pressure on the inguinal canal will prevent the contents of the hernia sac passing down the canal. If, instead of the pressure being exerted from the outside, the two layers of the inguinal canal are made to adhere to one another by fibrous tissue, the same result will be achieved. Therefore, this treatment is applicable to those patients who have indirect inguinal hernias which are completely reducible. This treatment does not apply to persons having incisional hernias or irreducible hernias, and it would also appear to us that it would not apply to direct inguinal hernias, although it has been used for such. The value of this treatment lies particularly in that group of patients who, because of various systemic conditions, are unable to undergo surgical procedure; and it is also advised in others for economic reasons.

The authors also draw attention to the fact that this type of treatment may fall into disrepute because it may be undertaken by individuals who have very little knowledge of the anatomy of the inguinal region who might be tempted to use the injection treatment, whereas they would not trust themselves to undertake a surgical cure of the condition.

In regard to the matter of healing of hernias, it has been always our teaching that one could rely very little upon the tensile strength of scar tissue in that if one relied upon scar tissue to hold a hernia, he would almost always encounter a recurrence, and in fact one of the common causes of repeated recurrences in the same individual lay in the fact that scar tissue was used for closure and the scar tissue gradually gave way. On the other hand, the actual suturing of fascia to fascia reduced to a minimum the area of scar tissue formation, and therefore the fascia itself is called upon to support the hernia. One of the causes of recurrence is the difficulty in bringing fascia to fascia, obtaining instead merely fascia to scar tissue. Therefore, in performing an inguinal hernioplasty, if one were unable to obtain fascia on the edge of the conjoined tendon (either owing to the fact that the fascia was poorly developed or that the muscle belly was so well developed that the fascia was out of reach, being some distance from the inguinal ligament), it was desirable to follow the method shown us by Dr. T. M. Joyce of Portland, who obtains a long strip of fascia from the edge of the external oblique and uses this to suture the external oblique down to the shelving edge of the inguinal ligament. This method in his hands, he states, has given him excellent results without recurrence in the last five years. This is an improved modification of the original McArthur's autoplastic suture in the radical cure of hernia in that the main value of the operation is the suturing of the cut edge of the external oblique with a live suture, under the cord to the shelving portion of the inguinal ligament, and then the suturing of the extra outer part of the fascia of the external oblique over the cord can be done with catgut or silk, that part being apparently unimportant. The main modification of the operation is that no suturing is done through muscle fibers, which will always cause scarring and destruction of the normal activity of the muscle.

It appears to us at the present time that such a method of treatment is preferable, particularly in view of the fact that it is well known that an indirect hernia cannot be always distinguished clinically from a direct hernia, because if the external ring is reasonably small one is not always sure whether the hernia sac comes down to the canal from the internal ring or from Hesselbach's triangle, and the one would be amenable to the injection method and the other probably not.

We believe that the operative treatment of inguinal hernia is so simple nowadays under local anesthesia, and so certain of a good result with the use of the strip of live fascia for suture material, that the use of any blind method, such as injection, is not in keeping with good practice.

⁂

Donald C. Collins, M. D. (1930 Wilshire Boulevard, Los Angeles).—The contributions of Doctor Girard and of Doctors Harris and White upon the injection treatment of hernia are both timely and noteworthy. They are to be congratulated upon presenting us excellently prepared studies of one of the most highly controversial subjects of the present moment in medicine. I do not wish to detract one iota from the credit that is justly due these authors, but several facts merit serious consideration in the proper evaluation of this problem.

The large American clinics and hospitals in the East and Middle-West, where this form of therapy was so enthusiastically begun on a large scale, some six years ago, have now found that the percentage of recurrences has been considerably increased over that experienced following surgical repairs. Thus, they have either markedly limited the indications for this mode of treatment or have decided that it should be discontinued. The complications that may follow injections cannot be lightly brushed aside as of no consequence. In my own limited personal experience during this past year, I have observed two fatal pulmonary embolisms, a secondary gangrene of the sigmoid and upper rectum, and two complete bowel obstructions resulting from the accidental escape of some of the injecting fluid into the peritoneal cavity.

Other objectionable factors in the injection method of therapy include the constant wearing of a "truss" day and night for a period varying from three to nine months following treatments. This is contrary to all surgical conceptions of optimum conditions for proper healing. The injection method does not guarantee that patients may again resume heavy work unless they have the additional protection of a "truss." The total amount of money expended by the private patient is about the same whether he is operated upon or injected. The only difference lies in the fact that the physician who performs the injections gets all the money instead of dividing it with the hospital.

During the past few years the conviction has steadily gained ground that, surgically, hernias should utilize, if possible, the patient's own fascia for suture material by either the McArthur or the Gallie-J. C. Masson method. Many of the failures in the past following hernioplasties were directly attributable to the use of improperly chosen foreign suture materials. Autogenous fascia does not slough out nor does such a hernial repair break down in the presence of infection. This generation of physicians has largely forgotten the bitterly learned truths of the Bassini era concerning the necessity of removing the hernial sac and transplanting the inguinal vas and its structures superficially under direct vision so as to insure a permanent cure.

Any injection method is of necessity an admittedly blind procedure. Injury to the ilioinguinal and iliohypogastric nerves is a serious complication which may lead to a diffuse weakness of the entire lower abdominal wall on that side, as we have observed to occur occasionally in a carelessly performed McBurney incision. Hematoma, thrombophlebitis, or injury to the contents of an irreducible hernial sac may lead to grave consequences. The sweeping and unproved contentions that this method of therapy can be safely used in all varieties of herniation is without foundation, and will not stand before the impartial scrutiny of established scientific facts. Any investigator, claiming to have healed a hernia permanently, must submit as evidence at least a five-year follow-up study. Injection therapy cannot be safely entrusted to the general practitioner who only occasionally treats a hernia. Thus, this method can only be safely employed by those who are doing this method of therapy daily. It is my belief that injections may be tried in those individuals cautiously in whom surgery is contraindicated either because of advanced age or due to grave organic disease.

These are some of the reasons why I firmly believe that the injection method of treating hernias is one of only temporary and fashionable interest. I predict that the use of autogenous fascial sutures will probably prove to be the ultimate solution to the entire hernial problem, and will give such a high percentage of permanent cures that many of our present concepts will be discarded as worthless.

Again, I wish to compliment both Doctor Girard and Doctors Harris and White on presenting such excellent and timely studies upon this important question. They have performed valuable pioneer work in an attempt to better our present hernioplasty results. Through efforts such as theirs the field of medicine is advanced and its scope of usefulness is widened; so that in the end men may live happier and more useful lives.

⁂

W. L. Weber, M. D. (Pacific Electric Building, Los Angeles).—I had the pleasure of hearing the writers at the California state meeting at Coronado in May, 1936. It was Doctor Girard who, although perhaps altogether unknown to him, first stimulated my interest in taking up the injection treatment of hernia. As a matter of fact, before the meeting of the American College of Surgeons held in San Francisco in October, 1935, I was definitely critical of and prejudiced against the treatment without, however, having had any personal experience with the method. I had observed a number of patients who had been injected, and the results, to say the least, were not encouraging. I even felt so strongly against the method that I wrote to a certain company giving as my opinion that if they should continue to refer their men for this treatment some serious untoward results would almost certainly occur, and they might be liable for damages because of their having referred the patients for the treatment.

On my way to San Francisco in October, 1935, in discussing the injection treatment with a number of other doctors, I expressed my opinion that the method, so far as I could judge, was unscientific, and certainly not based on sound surgical principles. However, after watching Doctor Girard inject a number of patients, and after having seen some of the patients whom he had injected a year or so before, I came away convinced that the method, in the proper hands and with the proper technique, was certainly entitled to a decent trial before condemnation. Some time after the San Francisco meeting I had the great pleasure of seeing Doctor Bratrud in Los Angeles, and he was good enough to visit our clinic and tell and show us much. The studies of Doctors Rice and Bratrud and others have demonstrated, in my opinion, that the method in the properly selected case has a distinct place in our treatment of hernia.

Statistics the world over suggest that the operative treatment of inguinal hernias is not all that is to be desired, and the fact that there have been so many methods evolved for the radical operative cure of hernia also suggests that operative treatment is not the last word. I need but refer to the article that appeared in *Surgery, Gynecology, and Obstetrics* of April, 1934, by Andrews and Bissell, in which they quote statistics from various authors who give a percentage of recurrences after operation varying from 8 to 32 per cent, and these results by men of standing. This article refers to the direct type of hernia, and I am certain that the percentage of recurrences of the indirect type is not far behind. These colleagues say that the statistics furnished by various operators in the direct type of hernia show, "The results are so bad as to constitute a major surgical scandal."

My experience, over a term of some twenty-three years, has convinced me, at least in so far as my own results are concerned, that the failures after operation and the appalling economic loss involved in all cases, whether the results are good or bad, clearly prove that operation for radical cure of hernia in every case is not warranted in the light of present knowledge of the injection treatment.

My personal experience with the injection method dates only from November, 1935, but since that time I have personally injected some thirty-six patients, and in every case there has been a decided improvement, and in the majority an apparent cure. In some of the very large hernias the results have been so remarkable that it seems almost incredible that injection of any solution could produce such an effect. In my small series of cases there have been no infections, no sloughing, no hydrocele of the tunica, no testicular atrophy, and in only one case has there been an untoward result, and that in a private patient, an extremely thin person suffering from bilateral hernia, in whom upon the first injection I must have struck the anterior crural nerve, because the patient was not able to stand upon his right leg, and for a number of days he complained of weakness in the leg. This patient has entirely recovered except that the right patellar reflex is still lost. The sensory disturbance in the anterior aspect of the thigh has recovered.

The properly selected case, in my opinion, is one in which the hernia is of direct or indirect inguinal type, easily reducible, and capable of continued reduction by a properly fitted, comfortable truss. I do not believe, at least at this time, that femoral and umbilical hernias are safe or proper types for injection. An important phase of the injection treatment of hernia is the tendency on the part of the operator to charge so much an injection. This, I believe, is wrong, because in the hands of unscrupulous or mercenary persons the number of injections can be augmented *ad libitum*. Furthermore, this method of treatment in any given case is much more troublesome and difficult than is the operative technique, and in my opinion it should be placed on the same financial basis, and like the operative treatment, it should not be undertaken by anyone who is not thoroughly competent to deal with hernia surgically.

The authors are to be congratulated upon the splendid presentation they have made, and I am certain that their writing will do much to stimulate others; at least, to consider the injection method and to regard it as an acceptable treatment in properly selected cases.

⁂

Doctors Harris, White and Girard (Closing).—The authors have repeatedly reiterated in their papers the necessity of confining this method of treatment to men properly trained not only in the technique of hernia injection, but also to those trained especially in surgical diagnosis and operative treatment of the inguino-abdominal region. The fact that this stand is maintained and emphasized by the discussers is appreciated. Too strong emphasis cannot be placed on the limitation of this method of treatment to men especially qualified in its use. It is realized that much harm and serious complication may result from injudicious employment of this method by men in general practice. The selection of cases and the indications for treatment must of necessity be made only by those qualified and trained in the details of its technique.

It is likewise true that all surgical operations may result in disaster when performed by incompetent and untrained operators. The necessity of limiting the use of any surgical procedure to trained men is obvious. Complications which occur in untrained hands must be blamed on the operator and not on the method of treatment. In a consideration of the injection treatment of hernia emphasis must be placed on the thousands of satisfactory results, without complications, recorded by men of unquestioned integrity and not on scattered reports and hearsay evidence on the complications experienced by men untrained in this procedure.

It is significant that in the 350 cases reported in these papers, no serious complications have occurred. Absence of serious complications in these cases is due both to careful selection of patients and to the proper conduct of the treatment. Improper selection of cases and improper conduct of the technique discredits not the treatment but its method of application.

It must be further reiterated that the injection treatment of hernia is not advocated as a substitute for surgical treatment, but is to be used as an adjunct in the treatment of certain selected cases. It is our purpose to demonstrate the feasibility and practicability of this method and to subsequently definitely determine the type of case in which it will have its greatest use.

ARTHRITIS—A MEDICAL PROBLEM*

By ROBERT STEWART PEERS, M.D.
Oakland

DISCUSSION *by Leonard B. Barnard, M.D., Oakland; Robert T. Pottenger, M.D., Pasadena; H. Gordon MacLean, M.D., Oakland.*

THE confusion of names, theories, and treatment which blankets the subject of chronic arthritis of uncertain origin is a most unhappy one. One is usually confronted, first, by a new dialect. The origin of each form is primarily in our lack of knowledge as to the source of the rheumatic syndrome, and that each is a production of clinical observation rather than scientific etiologic classification.

PROPOSED GROUPING FOR PATIENTS WITH ARTHRITIS

In proposing a grouping for patients with arthritis, I do so for the limited purpose of practical care. It in no way interferes with any particular theory. The infectious theory, the endocrine theory, the constitutional theory, and the allergic theory, are all of academic interest at this writing.

In accommodation to our lack of knowledge, any grouping has many discords. The life cycle of arthritis is at present without a beginning and many links are absent. Clinically, at the very best, we pick up the rheumatic syndrome in early pubescence.

ALLISON AND GORMLEY'S CLASSIFICATION

To orient ourselves, we are not discussing joint disease of known origin, which, in the classification of Allison and Gormley, is as follows: 1. Traumatic (sprains). 2. Bacterial (tuberculosis). 3. Arthropathes (such as tabes). 4. Constitutional (such as gout). We are interested primarily in joint disease of unknown etiology.

GROUPS FOR JOINT DISEASE OF UNKNOWN ETIOLOGY

As an expedient to group care it is desirable, in my mind, to group patients in this syndrome as follows:

Group 1

This large group contains those otherwise known as atrophic, infectious, rheumatoid, proliferative, and Type I. It is the polyarthritis of small joints whose onset occurs in most any age, but most frequently in the second to fourth decades, usually insidiously, with transient periods of remissions, but a slowly progressive, deforming type of pathology, resulting in atrophy and ankylosis. In my experience, it groups itself into three large distinct clinical divisions.

1. *The Acute.*—The more unusual method of onset (when adequate history is obtained). The patient is febrile with puffy, white, painful swelling of the joints, and with marked limitation of active and passive movements.

2. *The Chronic.*—The clinical group which divides itself into two subgroups—the early and late. First, the early, in which the symptomatology is predominant, with signs limited usually to the small joints. Second, the late, in which the proliferative pathology has more or less progressed, resulting in limitation and deformity, but yet in active state.

3. *The Arrested.*—The third large group in which the disease itself has become arrested, leaving more or less deformed joints, limited in movement and with general constitutional depression as the marked feature.

Group 2

The allotment in this grouping is based on pathologic progression and not a chronologic assignment. This large group contains those otherwise known as hypertrophic, osteoarthritic, osteochondrous, degenerative, and Type II. It is the type in which the large joints and the back are most frequently involved, characterized pathologically by degenerative changes. It divides itself into two large clinical divisions.

1. *Mid-Life Group.*—The disease becomes active usually during the fourth or fifth decade, and the patients divide themselves into two groups: those who are overweight and those who are underweight.

2. *Senile Group.*—The second large group occurs with senescence.

Group 3

This group, known as mixed or type 3, presents, clinically and pathologically, a varying mixture of the two preceding types, and is divided, clinically, into two divisions, depending upon which pathologic changes appear predominant.

Group 4

This is the group which I choose to call the arthralgias. The onset is at any age and presents questionable and variable pathology. It is a result of differential diagnosis, and presents many subgroupings, such as vasomotor instability, endocrine, arteriosclerotics, neurasthenics, and neurotics, blood dyscrasias, and a large miscellaneous group.

COMMENT

Besides the clinical picture and history, further support is gained for the above groupings in a simple laboratory procedure, a procedure well tested by others with consistency in results.

The sedimentation test is used in a variety of conditions. There are several methods of procedure. Our method is that of using four cubic centimeters of blood and one cubic centimeter of 3 per cent sodium citrate solution, and measuring the erythrocytic drop in millimeters over a period of one hour.

In a group of seventy-four selected, uncomplicated cases, of which thirty-seven were drawn from Group 1, thirty from Group 2, and seven from Group 3, it was elected to test the practical value of this simple procedure.

In Group 1, of the thirty-seven patients, unfortunately only twenty-eight of them were followed for any period of time. Twenty-four patients showed curves which paralleled their clinical improvement. In one the curve improved, but there was no apparent gratifying result in the patient's symptomatic report. In three the curves were unimproved and there was no improvement in the patient's general welfare.

---

* Read before the General Medicine Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

In the thirty cases in Group 2, all the curves were within normal limits.

In Group 3, three curves paralleled improvement and three showed improvement, but with no important improvement in the patient's own story.

ADVANTAGES OF GROUPING SYSTEM

This procedure serves, first, as an aid in grouping; second, as a diagnostic lead; and, third, as a method of measuring the patient's clinical response. It might be mentioned that secondary anemia (which so frequently, in textbooks, is spoken of as an accompaniment of this disease syndrome) has been encountered in our groups most infrequently and, therefore, would have no effect on our interpretation of the sedimentation test. Other factors contributing to change in the test should always be considered.

It is assumed that a usual systematic medical inventory is acknowledged. Unfortunately, this is usually banned for a lamentable enthusiasm to some publicized single method of assault. In all groups, orthopedic management (feet, posture, physiotherapy, and corrective exercises), is to be added.

SPECIAL FEATURES OF GROUPS 1, 2, AND 3

Space permits discussion of two features common to Groups 1, 2, and 3. The first, a fitting application of the basal metabolic rate, a now common procedure which shows a definite deviation in this disease syndrome. The test, as with any other test alone, remains an isolated laboratory procedure. Our normal range is based on statistical study of more or less normal subjects. We, by chart and table, correct for weight, height, age, sex, barometric pressure, room temperature, and the patient's temperature. So consideration should be given that the test is run in the morning, the particularly uncomfortable part of a rheumatic individual's day. A rheumatic individual has greater or lesser muscle groups quiescent from atrophy and inactivity. He or she is often ambulatory because of a spirit of determination. In reflection of the above, minus 5 to plus 15 per cent, is a conservative figure of the adequate normal range. The depression of metabolism in this disease is not a new observation. Its interpretation merits further consideration.

In 111 cases where the patients were culled from 314 under care and divided as follows—thirty-nine in Group 1, thirty-three in Group 2, fifteen in Group 3, and twenty-four in Group 4—the following was presented on initial testing under adequate circumstances. In Type 1, five gave a positive reading, one a zero reading, and thirty-four cases a minus reading. In Type 2, four gave a positive reading, one a zero reading, and twenty-eight cases gave a minus reading. In Type 3, three gave a positive reading and twelve a minus reading. In Type 4, thirteen gave a positive reading, one case a zero reading, and ten cases a minus reading.

Further analysis: The thirty-four cases of the thirty-nine cases in Group 1: thirty gave a reading of below minus four, twenty-one of the thirty-four were below minus nine, eight of the thirty-four were below minus fourteen, and one a reading below minus nineteen.

In Type 2, the findings are much the same in that twenty-two of the twenty-eight cases gave a reading below minus four, seventeen of the twenty-eight gave a reading below minus nine, eight of the twenty-eight gave a reading below minus fourteen, and two gave a reading below minus nineteen.

In Type 3, a group smaller, but with similar tendencies, in that ten of the twelve cases gave a reading of below minus four, seven of the twelve gave a reading of below minus nine, and three of the twelve gave a reading of below minus fourteen.

For completeness' sake, those in Group 4 were included. In this group a different inference is evidenced in that of the ten cases with a minus reading, nine were below minus four and only four below minus nine, with one below minus fourteen.

THYROID THERAPY

The question arises: What response do these individuals give with thyroid therapy? In this group, thyroid, medically, is purely stimulative and is borne out in their tolerance to thyroid therapy. In each of the three groups, a quarter to one and one-half grains a day is usually most adequate. In the arrested of Group 1, tremor, palpitation and nervousness soon intervene, most frequently with the smallest of doses.

Type 2 endures, apparently, the stimulative therapy with better grace.

Type 3 follows closely in its response to the above two.

The low metabolic rate in this group is not due to the lack of thyroid hormone, but is brought about in some other fashion. The patient's improvement and well-being after the first test are more important than any subsequent basal metabolic rate. It is assumed that ordinary medical consideration is given in administration of a drug of this potency.

SUGAR TOLERANCE

The rheumatic syndrome displays another common feature not new in one sense, but particularly interesting from a practical point of view, and of interest with the advent of the new one-hour, two-dose sugar-tolerance curve.

The delayed sugar removal from the blood of patients suffering from arthritis is not specific with this disease group. This manner of behavior apparently is exhibited in all three groups.

It is not necessary to reiterate the normal phenomenon with the old type sugar-tolerance test, except to mention that our standard is for fasting blood sugar—90 to 120 milligrams, and the normal individual has a curve within the fasting range in two hours.

TEST OF EXTER AND ROSE

The new test proposed by Exter and Rose is based on the well-known phenomena that, when more sugar is administered to normal individuals, more sugar will be utilized, while the reverse is true in diabetes. This study is conducted on definitely non-diabetic individuals.

The new test is as follows:

1. One hundred grams of glucose in 650 cubic centimeters of water and divided into two equal parts.
2. Fasting blood-sugar and urine specimens collected, and the first dose given (50 grams of sugar, 15 per cent solution).
3. The 30-minute blood and urine specimens collected.
4. Second 50 grams are given.
5. The 60-minute blood and urine specimens collected.

To quote Exter and Rose:

"The typical criteria for the normal one-hour, two-dose test is:

"1. Fasting blood sugar within the normal limits.

"2. Rise in blood sugar that does not exceed 75 milligrams in a 30-minute sample.

"3. The blood sugar in a 60-minute sample is: (a) less; (*b*) the same; (*c*) or does not exceed the 30-minute sample by five milligrams."

The patients used for this study present a small but adequate cross section of active arthritics of Groups 1, 2, and 3. The total number of cases was forty-nine. The total number of cases with old type blood-sugar test was forty-nine. The total number of cases with the new type test was forty-three. The total number of cases with new and old type tests was forty-two. Twenty-three were derived from Group 1, fifteen from Group 2, and eleven from Group 3.

On analysis of the forty-two cases checked with the new and old type tests, thirty-five showed delayed sugar removal in the old type test, leaving seven who showed a normal curve. Of the thirty-five showing delayed sugar removal by the old test, checked by the new method as outlined above, twenty-one showed abnormal or diabetic-like (?) tests. In these twenty-one cases, six showed the atypical deviation in the first half-hour reading, that is to say, the rise was more than 75 milligrams in the 30-minute blood sample. Three showed a rise of more than 75 milligrams in the first blood sample, and a rise of more than five milligrams in the 60-minute sample. Twelve were abnormal or diabetic-like (?) in that they showed a rise of over five milligrams in the 60-minute blood sample. Of the seven that showed a normal curve by the old test, three showed abnormal or diabetic-like (?) tests. Of the forty-two tested by the new manner, eighteen showed a normal new type test.

In concentrating these figures in another manner of speaking, 83 per cent showed delayed sugar removal by the old test, and 57 per cent showed abnormal or diabetic-like (?) curves by the new test.

It has been suggested by others that the phenomena of delayed sugar removal arises from the curtailment of the blood supply. However, this curtailment of the blood supply exists in a certain extent in the arthritic during a remission, particularly those in Group 1.

In the normal subject, the ingestion of glucose so stimulates the so-called "insulin-glycogen mechanism" that almost any amount can be handled without hyperglycemia. Briefly, blood-sugar readings are augmented by glucose, principally from the intestine and glycogenolysis. The factors that depress the blood-sugar level are glycogenesis, glucolysis, and fat formation, and, in unusual circumstances, glycosuria. In the rheumatic syndrome we have a transient hyperglycemia with only a rare glycosuria. There is a delay, apparently, in the mechanism which controls glycogenesis and glucolysis. The above mechanisms are under the control of the pancreatic hormone, executed with and by the vegetative nervous system.

The above phenomena is no different than our depression of metabolism in that it is another reflection of a constitutional disease and is in no sense related as an eitologic factor. However, we are led to the following conclusion: That false readings may be expected with the new type, two-dose sugar-tolerance curve in cases where diabetes is not an established diagnosis and the rheumatic syndrome is an active factor. The delayed sugar removal is another manifestation of disturbed physiology in the rheumatic syndrome, and this phenomena should be considered in the management of any case of arthritis, especially in those patients in Group 1 of the chronic and arrested types.

IN CONCLUSION

In comment of the above, it is most necessary to group an arthritic subject for care in a manner of his clinical progress. A furtherance in their alignment and advance is offered in the sedimentation test. The true arthritic is a nonmyxedematous individual. Thyroid therapy is stimulative medication only, tolerated in small doses with a low threshold for undesirable side effects. The new two-dose, one-hour sugar-tolerance test does not supplant the older test in this syndrome.

No larger field offers itself for the tonic use of insulin in supportive treatment. A balanced medical perspective with expedient application, rather than therapeutic sniping, offers this group a promise of remission.

2939 Summit Street.

DISCUSSION

Leonard B. Barnard, M. D. (2939 Summit Street, Oakland).—Arthritis of unknown origin has been called the "no man's land" of medicine. Every division, both surgical and medical, has "taken a fling" at it, with resultant confusion in terminology and treatment.

When we consider that its incidence comprises a greater total of chronic disease than diabetes, heart disease and tuberculosis combined, we must realize it is entitled to a more important position and a studied approach.

It is a general disease with joint manifestations. Therefore, the primary attack must come from the internist, who should draw freely on the coöperation of the other specialties. It has been authoritatively stated that 50 per cent of the afflicted have lost their confidence in the ability of the medical profession to treat them. We must accept this as a challenge and improve our position concerning the disease.

The three laboratory procedures which Doctor Peers has presented are an illustration of the awakened interest in this topic, and tend to bring home to us the general nature and at the same time the multiplicity of form of this disease.

Let us always remember this is a complex disease. We cannot neglect the basic orthopedic principles of protection from deformity, lest we be left, when the remission occurs, with severe secondary manifestations, which make the respite of small functional value.

It is possible that we may have to come to the institutional care of a large number of these afflicted, as has been so well exemplified by the Swedish National Hospital for Rheumatism, before proper care can be administered.

I agree with Doctor Peers, that in the meantime, by gradually strengthening our laboratory procedures from the standpoint of diagnosis and prognosis, we can hope for a large measure of remission.

⁂

Robert T. Pottenger, M. D. (65 North Madison Avenue, Pasadena). — Doctor Peers' paper illustrates the meaning of the definition given by the American Committee for the Control of Rheumatism, that arthritis is "a generalized disease with joint manifestations." Physiologic disturbances occur not only in the skeletal system, but also in the circulatory system, the digestive tract, the nervous system, and the general metabolism.

Doctor Peers has again shown that a delay in the removal of sugar from the blood can frequently be demonstrated in all types of arthritis. Therapeutic deductions from laboratory data are difficult of evaluation when each procedure is only one factor in a general program. When laboratory observations suggest a radical change in the diet, the effects are particularly difficult of evaluation; as the resultant changes in the physiology may be due to additional factors introduced in the new diet, rather than to the correction of the hypothetical abnormality. This observation of an apparent weakness in the mechanism of sugar metabolism (which is shown by the delay in removing sugar from the blood) gave rise to the use of a "low caloric diet," and also a "low carbohydrate diet" in the treatment of arthritis. In practice these may amount to the same thing, as a low caloric diet must still have adequate amounts of protein which becomes largely of animal origin with a consequent increase of the fat content. The dehydrating effect of this diet was noticed, and Pemberton, in 1934, called attention to the apparent therapeutic value of this effect.

As you know, the average diet contains ten or more times as much carbohydrate and protein combined as fat, while a ketogenic diet contains four times as much fat as protein and carbohydrate. A low caloric diet might contain three times as much protein and carbohydrate as fat, and if three tablespoonfuls of cod-liver oil were given each day, twice as much. My observations show that a dehydrating effect begins when there is about two times as much protein and carbohydrate as fat in the diet, and the loss continued so that when the fat has been increased to one and one-half times the combined protein and carbodrate the loss of water amounts to three or four pounds. The water loss observed may be due to the reduction in the carbohydrate intake, or the metabolic effect of the fat, or to other factors; since the diet has been altered not only in a reduction in the number of calories and the proportion of fat, carbohydrate, and protein, but also in the mineral and vitamin content, as vegetables make a large portion of the bulk of the diet. Furthermore, the water loss may simply be the result of a favorable alteration in the metabolism rather than the cause of it.

After a scientific prescription of a diet there remains the variable of the patient. Unfavorable results from a prescribed diet may be due to the patient's failure to eat the foods thereon, or perhaps more rarely to assimilate them. Several patients who were doing poorly on a low carbohydrate diet were found, on weighing their food intake, to be eating about 25 grams of protein a day, and this largely of vegetable origin. Simply increasing the protein intake to about 60 grams was followed by clinical improvement.

The importance of particular factors in the diet can be more readily evaluated if the whole diet is studied in respect to all the food factors in at least as exact terms as the erratic method of weighing foods will allow. If dietetic studies in arthritis are reported in this way it will be possible to correlate the work of the various investigators, and we may hope for more rapid progress in this one phase of the arthritic problem.

H. Gordon MacLean, M.D. (230 Grand Avenue, Oakland).—The grouping of arthritis presented by Doctor Peers is a very workable one. It is very similar to the older grouping of atrophic, hypertrophic, and mixed types of arthritis. His fourth group of arthralgias covers nondescript types, many of which, however, as times goes by will fit into one of the first three groups.

The use of the sedimentation test indicates that Group One is markedly related to infection, and that Group Two is not so closely related to infection.

His findings in regard to basal metabolic rate are very similar to those by Boothby in 1922, in which 90 per cent of all arthritics fitted into the basal metabolic readings of minus fifteen to plus fifteen. He has shown that the tendency in all groups concerned is toward a slightly minus reading, and that this is not at all typical of arthritis.

The sugar tolerance test, using the one-hour two-dose method, still continues to bring out the fact that there is a disturbed carbohydrate metabolism in arthritics, but here, again, this is not any real characteristic of arthritis.

All of the suggestions given lead one to the conclusion that arthritis is a constitutional disease, with many factors being the cause. It is necessary to treat each arthritc individually. If he is underweight, the use of insulin to bring up his weight is highly beneficial, as in other individuals who are undernourished. Also, if he is overweight it is necessary to have that weight reduced. Diet, in other words, should be suited to the individuals: high caloric for the undernourished and low caloric for the overnourished.

Removal of infection is necessary in all types of arthritis when it is found. Medication at the present time is only of value for the relief of symptoms.

Rest would be ideal for most arthritics, and some day, perhaps, we can treat them in the same way that we today treat the tuberculous individual, getting the disease in hand early and not late, as is our custom at the present time. The difference between the treatment of tuberculosis and the treatment of arthritis today is that the tuberculosis individual gives his entire time to taking care of his disease, while most arthritic individuals continue working and pay attention to their treatment only as a side issue.

The need for well-regulated institutional care of arthritis over a long period of time is very great. Good results will be obtained when we have the combined efforts of the internist, the orthopedist, the physiotherapist, and the occupational therapist, all working as one.

HYPERPYREXIA: AS AN ADJUNCT IN THE TREATMENT OF CEREBROSPINAL AND KAHN-FAST SYPHILIS*

By James E. Potter, M.D.
Bremerton, Washington
Francis H. Redewill, M.D.
and
E. G. Longley, M.D.
San Francisco

Discussion *by Rodney F. Atsatt, M.D., Santa Barbara; Norman N. Epstein, M.D., San Francisco; Ross Moore, M.D., Los Angeles.*

ROSENBLUM of Odessa, in 1876, was the first to inoculate, with malaria, patients suffering with general paresis and other mental diseases. In 1878 Oks translated this paper into German.[1] Wagner Von Jauregg, while in Constantinople, thirty years later, popularized the malaria treatment of neurosyphilis.[2]

ARTIFICIAL FEVER AND MALARIA TREATMENT

Artificial fever production in recent years has superseded the malaria treatment for three reasons:

---

* Read before the Dermatology and Syphilology Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25 to 28, 1936.

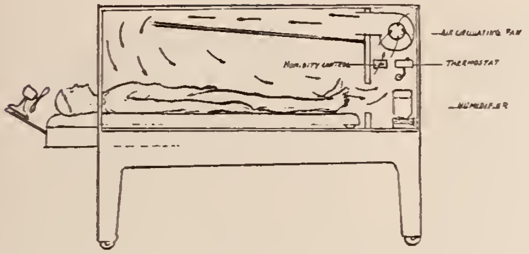

Fig. 1

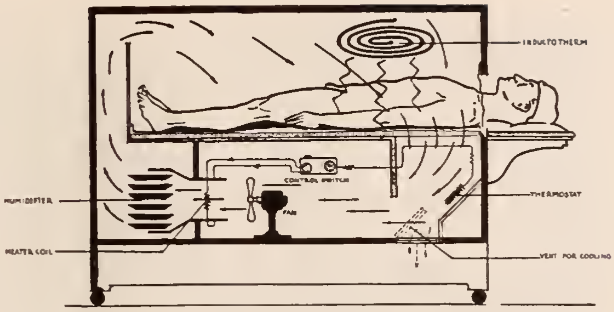

Fig. 2

Fig. 1.—Diagram of Kittering Air-conditioned cabinet as described by Simpson, Desjardins and others. Note the humidifier, thermostat, air circulating fan, humidity control and fan that blows air on head and face. Temperature in the cabinet ranges from 150 to 160 degrees Fahrenheit and humidity 50 to 75 per cent.

Fig. 2.—Kimble cabinet. Note thermostat control switch, heater coil, humidifier and the heavy insulated coil of the inductotherm suspended above the patient's chest and abdomen. Temperature in this cabinet at all times is 100 degrees Fahrenheit. Fever is generated in the patient solely by magnetic waves from the suspended coil entering the patient's body.

1. The former is twice as effective, curing 65 per cent of 742 cases.

2. The mortality from malaria therapy is from seven to ten times as high as with artificial fever heat. In the literature there are eighteen deaths with the treatment of 700 patients with hyperpyrexia, whereas the malaria therapy death rate is 10 to 30 per cent.[3] We three have treated over 800 patients in the past six years, with no deaths. Neymann of Chicago has treated over 1,000 cases by this method, and his death rate is nil. Desjardins of Mayo's treated 362 patients, with one death.

3. When a syphilitic is infected with malaria there are two diseases to treat instead of one. Other superimposed infections have also been recommended, but the aim in the past five years is to get away from the production of fever by such infectious agents as rat-bite fever, relapsing fever, and malaria.

DIATHERMY

In previous reports by Potter [4] and Redewill,[5] over 200 cases of neurosyphilis and Kahn-fast cases were described, having been treated with diathermy with very successful results. However, there are several disadvantages with the use of this modality, such as the binding of patients with large electrodes, packing around the patient rubber sheets and blankets, all of which add greatly to their discomfort. Kettering and Sittler [6] of the General Motors Company brought out an air-conditioned cabinet with the use of ultra-high frequency electric currents applied by means of condenser discharges of a modified short-wave radio transmitter. They pointed out that the air-conditioned cabinet was to dissipate sweat as it collected on the skin surface, and to prevent arcing and burning of the skin as a result of concentration of short radio waves in the drops of sweat. Accidentally, they discovered that their cabinet would generate fever in a patient just about as satisfactorily with the air-conditioned apparatus going and without the short-wave radiation. Since then they have used solely the air-conditioned cabinet to produce in patients fever ranging from 105 to 107 degrees Fahrenheit (Figure 1). They have lent fifty-five of these units to medical research centers to produce hyperpyrexia in all types of acute and chronic infectious cases, and some of the results have been reported. (Simpson [7] and Desjardins.[8])

The great drawback in the use of cabinets that attain a temperature of 160 degrees Fahrenheit, thereby attempting to raise a patient's temperature with heat applied from without the body (which is also the same principle that is used through hot-water baths, electric light and infra-red cabinets), is that the patients so treated have a pulse rate twenty to thirty beats to the minute higher than those patients that are treated by modalities such as diathermy and electromagnetic currents that generate the heat within the body.[9] Therefore, as can naturally be expected, patients that are treated for five or six hours with the unnatural method of attempting to force heat into the body from without show a more frequent tendency of displaying symptoms of heat collapse. This is probably due to the severe strain placed on the sympathetic nervous system, when such heat is applied to the whole skin surface area. When fever heat is developed by electric magnetic current, such as the inductotherm generates, and the patient lies in an air-conditioned cabinet for six to nine hours, with a temperature of the cabinet of not over 102 degrees Fahrenheit, the patient is not only a great deal more comfortable, even with a temperature of from 105 to 107 degrees Fahrenheit, but shows no tendency to have any of the symptoms tending toward the ultimate heat collapse. It would seem, therefore, that by far the more preferable type of hyperpyrexia cabinet to use would be the latter type, which is known as the Kimble (Figures 2 and 3). We three presenting this paper have been fortunate in being able to use such Kimble cabinets in Bremerton and San Francisco in treating syphilis and gonorrhea infection and their complications.

TWO METHODS OF PRODUCING FEVER HEAT

All the different methods of producing fever heat can be divided into two classes: in the first, the environmental temperature of the media about the patient is maintained at a level higher than the internal temperature of the patient;[10,11,12] and in the second, there is a group of applications in

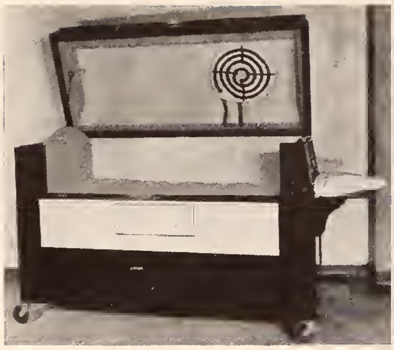

Fig. 3

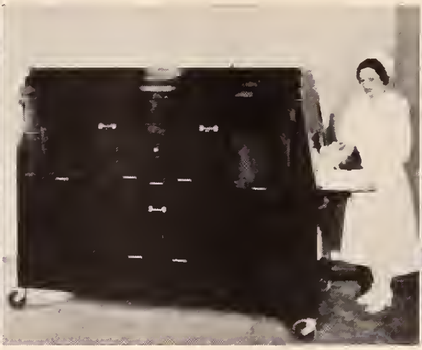

Fig. 4

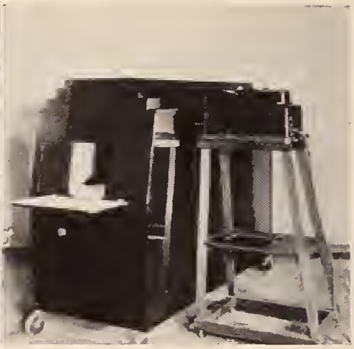

Fig. 5

Fig. 3.—Kimble cabinet (General Electric) with the top lifted and side panel dropped down. The patient lies on sponge rubber, 1½ inches thick covered with white rubber cloth and terry cloth. Note the inductotherm coil attached to inside of top. When the lid is lowered, the coil can be lowered or raised at will within the proper distance of the patient's chest and abdomen.

Fig. 4.—Kimble cabinet, side view when closed and holding a patient. Note panel doors. Upper door can be opened clear across the cabinet or just a small door can be opened for use in waiting on the patient. Lower door opens into heating mechanism that can be easily regulated from without.

Fig. 5.—Kimble cabinet, end view showing inductotherm attached. This inductotherm is attached to the suspended coil shown in Fig. 3.

which the temperature of the atmosphere about the patient is maintained at a level lower than the internal temperature of the patient. The first type includes hot baths, steam, electric light, infra-red and hot-air cabinets; the latter group includes diathermy, short wave and ultra-short wave bipolar modalities and electromagnetic radiation. This last modality is applied either in specially constructed blankets or in cabinets with the magnetic coil suspended above the patient.

For the past seventy-five years factors have been used to raise the temperature of the body with mud baths, hot-water baths, electric-light cabinets, steam cabinets, infra-red cabinets, and others. Where the temperature has been raised to not over 102 degrees, probably no untoward results have been noticed, if the applications have been applied for short periods of time. But in modern hyperpyrexia, with the raising of the temperature from 104 to 107 degrees Fahrenheit for a period of five or six hours, this method of raising the temperature is not only inadequate, but dangerous, because many patients so subjected show signs of heat collapse. Where heat is thrown into the body from the outside, the striking thing that is noticed is that the patient's pulse is, as said above, twenty to thirty beats a minute more rapid than when the heat is induced within the body.

As to the electromagnetic cabinet method, how near does it simulate nature's own means of producing heat? Does it violate any physiologic laws? Is it applicable to the sick and feeble patient? The answer to these questions are obvious as one becomes acquainted with the method.

BIOPHYSICS OF NEW CABINET THERAPY (KIMBLE)[13]

How the electro cabinet works is briefly as follows: The patient is placed in a specially designed cabinet. The temperature of the air in this cabinet is maintained automatically between 99 and 100 degrees Fahrenheit. The relative humidity approaches 70 per cent.

From a special adjustable coil suspended above the patient's chest and abdomen, a high-frequency magnetic wave is projected through the body tissues (Figures 4, 5, and 6). Due to their biophysical properties, these waves change into heat waves in the more conductive tissues of the body. More conductive tissues are the blood, vascular organs, and the muscles. Within one to two hours the internal temperature of the patient is elevated 3 to 5 degrees Fahrenheit. The magnetic wave is then shut off. From this point on the artificial fever is similar to a natural fever. In other words, we have replaced only the chill of a natural fever with the induction and release of artificial heat within the body by a biophysical agency.

It stimulates a natural fever in the following ways:

1. The internal temperature of the patient is always higher than the environmental temperature.

2. Heat at all times can leave the skin by radiation and conduction. (The skin is never forced to absorb heat.)

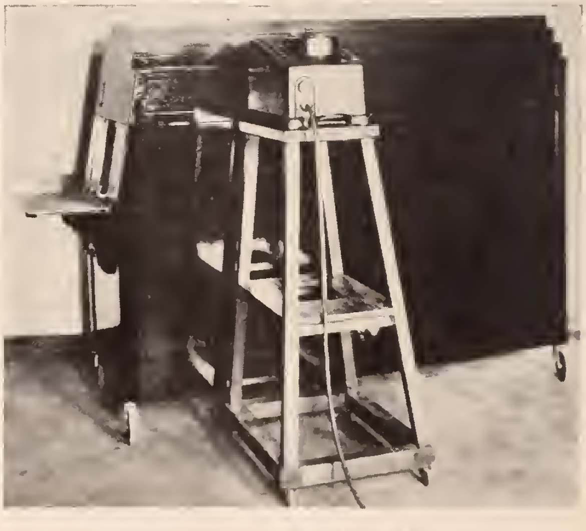

Fig. 6.—Kimble cabinet, lateral view with inductotherm attached and hooked up to line switch.

3. Some heat is lost by evaporation of perspiration (relative humidity 70 per cent).

4. The body produces its own energy for the continuation and further elevation of the fever. (By acceleration of metabolism.)

These factors, together with other features incorporated within the cabinet, such as a soft mattress, intermittent circulation of air, etc., keep the patient comfortable. If a patient is comfortable he is not irritable and restless. This permits the use of a small amount of sedatives.

There are practically no contra-indications for the magnetic cabinet type of thermal therapy. One caution is mentioned, namely, that every patient should be examined thoroughly in order to ascertain that no other intercurrent disease is present for which a fever would be contra-indicated.

TECHNIQUE

Preparation of Patient for Hyperpyrexia.—A careful physical examination should be made of each patient previous to treatment, including general physical examination, basal metabolism, electrocardiograph, blood pressure, blood and spinal Wassermann. Two following tests are especially useful in evaluating the behavior of the circulatory and nervous systems to hyperpyrexia: (1) Exercise test, to determine how quickly the pulse will return to its normal rate after exercise. (2) Cold pressor test[14] for early diagnosis of essential hypertension.

Sedatives. — Of the numerous sedatives advocated, we find the best ones to administer previous to and during hyperpyrexia treatment are: Two teaspoonfuls of pentabromids in water by mouth, and one-half grain of codein phosphate hypodermically one-half hour before beginning treatment. Repeat the codein during treatment for restlessness that may occur in the first hour of treatment. We find the barbiturates are somewhat depressing to the circulatory system, that morphin may be the direct cause of apnea during treatment, and scopolamin or hyoscin have a tendency, especially in neurosyphilis cases, to render the patients excitable and even mildly maniacal and difficult to control.

Stimulants.—Outstanding stimulants for weak pulse are caffein sodium benzoate, coramin (ampoules), hot coffee and carbogen (carbon dioxid 5 per cent, oxygen 95 per cent), inhalations for patients with disturbed respiration. In pending heat collapse, adrenalin is contra-indicated because, as said above, it contracts the superficial capillaries, thus retarding loss of heat through the skin.

COURSE OF TREATMENT

No two patients behave just alike under treatment, however, as Clarence A. Neyman says, concerning the new electromagnetic induction, creating heat within the patient, rather than applying heat from without, as followed by other forms of treatment, "one can maintain temperatures of 41, or even 42, degrees centigrade, or up to 106 degrees Fahrenheit, or five, six, seven or eight hours with comparative ease and without taking a great risk." Neyman, in discussing Desjardin's paper on fever therapy,[15] says: "We use electromagnetic induction now in combination with the cabinet, where the temperature of the cabinet never rises above 105 degrees Fahrenheit. The cabinet will not in itself produce fever at all, but simply serves as a sort of blanket in which the patient can move freely. With this sort of apparatus, patients in advanced stages of diabetes, with organic heart disease, with advanced arteriosclerosis, with diseases of the liver and the like, have been and are being treated, and our death rate remains virtually nil in over one thousand cases."

ACUTE SYPHILIS DOES NOT RESPOND READILY TO HYPERPYREXIA

What we mean by this is that it requires many very high fever heat treatments to kill the spirochete in the human body so that the patient is actually rid of the acute syphilitic infection, whereas in the chronic, and especially the neurosyphilitic, comparatively low fever heat will produce remarkable results—symptomatically speaking. And especially in syphilitic aortitis cases does fever heat produce striking results.

OTHER OBSERVATIONS

A specially trained nurse should be in constant attendance during a fever-heat treatment. There are scores of important items to be carefully looked after while giving such a treatment. To overlook any of them may invite disaster. We have not the space here to write down all the "Do's and Don'ts," nor can one become skilled in giving fever heat by reading a list of warnings. A fever-heat nurse is in the same category as an anesthetist, and must be actually trained under skilled hands. Simpson et al.[16] loaned out over fifty Kittering machines to various clinics, as we mentioned above, but they would not allow any of their machines to be used until nurses who were to handle the cabinets were trained for six months in the Dayton hospital.

LABORATORY FINDINGS

During fever heat a leukocytosis occurs; there is a drop in the sedimentation-test reading; during fever therapy the systolic pressure drops 20 to 30 points, and the diastolic during height of the fever often drops to zero. There is a great loss of chlorids which have to be replaced by giving normal salt solution by mouth. Because of the piling up of sodium in the system there is a tendency to an alkalosis; therefore, fruit juices are contra-indicated during treatment.

REPORT OF CASES

Case 1.—J. H. M. This patient has had a Kahn-fast blood and spine for twenty-two years. He has had innumerable courses of neoarsphenamin, tryparsamid, bismuth, and iodids. All previous treatment has been unable to reduce his serology, and aseptic fever is the last resort. The patient went through his first two treatments without incident, maintaining a high temperature of 105 degrees and over for three hours. A temperature was reached of 105.4 degrees.

His basal metabolism was minus 19m, and one-quarter grain thyroid was given to correct this; the same to be taken twice daily. Following the third treatment, his Kahn reaction was negative.

October 10, 1935—The patient states that he has a feeling of gusto and vigor, and that his well-being is sustained. Kahn is negative after the third treatment. Eating well and sleeping well.

October 16, 1935—The patient's fourth treatment. Came in feeling fine. Temperature was not elevated so high this time.

Treatment well sustained and patient comfortable. The blood Kahn taken following treatment returned negative. Laboratory reported that there was no doubt about it.

* * *

Case 2.—K. The patient has had chronic tertiary lues for years. Came to us complaining of shortness of breath and pain in the chest, around the region of the aortic interspace. X-ray showed a definite widening of the aortic arch. A diagnosis of vascular syphilis with aortitis was made. The patient has had three years' treatment with neoarsphenamin, mercury, and bismuth. He continued to complain of pain and shortness of breath on exertion. High temperature treatment was instituted today. The patient went through his first treatment without any trouble whatever.

October 13, 1935—The patient states that since his first treatment he has lost his rheumatic pains in shoulders and legs (tabetic ?). He feels generally improved and does not become so short of breath. He passed through this treatment without discomfort, but began to complain of pain over his heart toward the end. He was given HMc No. 2 for restlessness. It was found that temperature could be raised provided the humidity was maintained around 38 to 40 per cent, and with less dry-bulb heat.

October 14, 1935—The patient feels a little weak and shaky today, and complained of pain again in his shoulder (right). His occupation may have something to do with this, as he is compelled to work overhead. Otherwise he feels well.

UNSKILLED HYPERPYREXIA TREATMENT IS DANGEROUS

Although the great majority of the cases treated in the electromagnetic cabinet progress very satisfactorily with no untoward affects during treatment, however, anyone doing considerable amount of hyperpyrexia work is bound to get hold of a very troublesome case once in a while, even demanding the best skill of the doctor and nurse to pull the patient safely through the treatment, as the following will illustrate:

Case 3.—H. R. B. Age, 52. Diagnosis: Tabes, optic atrophy and syphilitic aortitis with myocarditis and severe anemia. The patient was treated on April 16, 1935, at Bremerton, Washington, by two of us. 5:15 p. m.—Temperature, 98.8; pulse, 72. Temperature of cabinet through treatment ranged from 100 to 104 degrees Fahrenheit. Inductotherm cut off. Time, 7:00 p. m.—Temperature, 105.4; pulse, 120. Inductotherm cut off. Time, 7:45 p. m.—Temperature, 105.2; pulse, 118. Inductotherm cut on. Time, 8:15 p. m.—Temperature, 107.2; pulse, 126. Inductotherm cut off. From this point the temperature rose in one hour to 108. Pulse, 158; temperature continued increasing slightly and at 11:00 p. m.; 108.8 pulse; 170; 1,000 cubic centimeters of normal saline solution intravenously. Carbogen gas inhalation given constantly. Pulse thin-running and irregular. Caffein, 7½ grains, given. Patient cyanotic around the ears, hands, and feet. Ghastly pallor about the face, reflexes nil. 12:30 a. m.—One thousand normal saline solution, intravenously. 12:45 a. m.—Temperature, 108; pulse, 160. Beginning violent seizures and convulsions of feet and hands; then arms and neck; then of whole body—the same lasting about twenty minutes. 1:30 a. m.—Temperature, 106.8; pulse, 140. One thousand normal saline solution intravenously. Convulsions beginning to lessen in severity. 2:15 a. m.—Temperature, 105.2; pulse, 132. Pulse very feeble. Caffein, 7½ grains, given. 2:45 a. m.—Temperature, 104; pulse, 132. Patient cooling down. Ice water to legs and arms. 3:15 a. m.—Temperature, 103.2; pulse, 130. Pupillary function returning. Patient very restless. 4 a. m.—Temperature, 102; pulse, 124. Involuntary feces and urine; five movements in one hour. 4:30 a. m.—Temperature, 101.2; pulse, 120. Patient moaning and tossing about a great deal. 5 a. m.—Temperature, 101; pulse, 120. Patient beginning to regain consciousness. From 5 a. m. to 10 a. m. the patient gradually cooled to normal. Mentality was hazy. The patient had severe pain in lower back. Blood pressure throughout the treatment averaged 92 systolic and 30 diastolic.

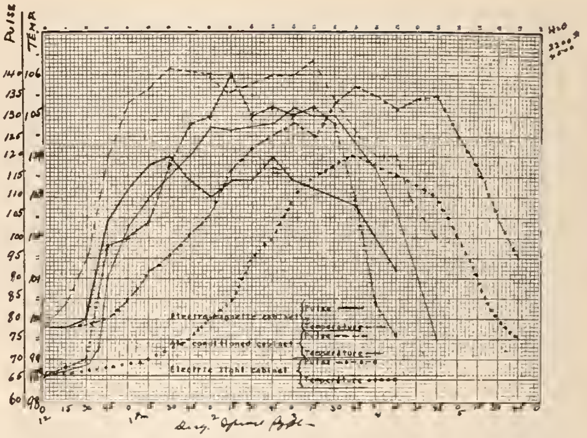

Fig. 7.—Temperature and pulse curves of same patient given treatment in three kinds of cabinets. Note in the Electro Magnetic Cabinet the temperature curve (marked in fine dots and crosses) runs much higher than the pulse (heavy black line). In the air-conditioned cabinet the pulse (in dashes) runs much higher than the fever curve (fine line). Note that in the electric high cabinet the pulse and temperature start much slower with the pulse (in dots and dashes) running much higher than the fever curve (in fine circles).

COMPARISON OF TREATMENTS IN THREE TYPES OF CABINETS

Treating patients in electric light, air-conditioned and electromagnetic cabinets, the comparable temperature and pulse curve are shown graphically in chart (Figure 7). The disadvantage of electric-light cabinet is that it takes too long to produce adequate fever, so that the patient is all tired out, restless, and nervous before the height of the temperature is reached. Secondly, throwing this type of heat into the body from without produces an undue amount of weakness in the patient, manifested by unusual rapid pulse, and the patient leaves the cabinet in a much more exhausted condition. Patients treated in the air-conditioned cabinet, with the temperature of the cabinet ranging from 140 to 160 degrees Fahrenheit, the required fever is arrived at in about the same time as with the electromagnetic cabinet, but the average pulse rate in a series of cases was twenty to thirty beats faster per minute in the former types of cabinet as compared with the electromagnetic type. Patients emerge from treatments in the Kimble (electromagnetic) in a far better condition, stronger, and more contented than those who are treated in either of the other two types of hyperpyrexia equipment. Another advantage of the electromagnetic type of cabinet is that it cuts short the duration and number of treatments required to obtain therapeutic results.

RESULTS OF TREATMENTS

Kahn-fast cases: number, 107; cured, 88. Kahn two plus, 8 cases. Unimproved, 8 cases. Cerebral spinal fluid positive, 48 cases, with high cell count, globulin present in decided amount, and high

Syphilis Treated With Hyperpyrexia and Chemotherapy

Type of Cases	Number of Cases	Blood Test Before Treatment Started	Blood Test After Treatment	Number of Fever Treatments	Type of Treatment Chemotherapy	Spinal Fluid Findings	Remarks

chlorid of gold curve. Average number of fever-heat treatments, 14. Gold chlorid curve, negative, 28. Improvement in cell count, globulin, and gold curve, 9. No improvement or discontinued treatment, 11. Neurosyphilis, 45 cases. All patients in this group who completed sufficient number of treatments were markedly improved from standpoint of manifested symptoms. Gold chlorid curve became negative in 18, the curve markedly lowered in 13. Slight improvement, 8. No improvement, 6. (Figure 8.)

CHEMOTHERAPY

In practically all of these cases, active treatment with bismuth, arsenic and iodid was followed. Indeed, tryparsamid three-gram doses, bismuth salicylate, and iodobismuthol were often pushed to tolerance. It has not appeared that it in any way affected the course of the patient's progress while giving the fever-heat treatment to also give the arsenic and bismuth medication directly before the hyperpyrexia, or in between the series. However, it has seemed unwise to us to burden the patient who is undergoing high-fever therapeusis, with heavy metals while he is under the influence of sedatives. Therefore, our practice has been to give the arsenic and bismuth between hyperpyrexia treatments. (Figure 9.)

CONCLUSIONS

1. Physical agents used for the production of artificial fever can be grouped in two classes: (*a*) Cabinets operating at temperatures lower than the temperature of the patient. (*b*) Cabinets operating at temperatures higher than the patient's fever.

2. With electromagnetic induction stimulating fever in a patient in a cabinet that has a temperature of only 100 degrees Fahrenheit, the pulse is twenty to thirty beats slower per minute, as compared with treatment in light and air-conditioned cabinets. With this magnetic induction type of treatment, the patient receives more rapid and satisfying therapetic results with less danger of heat collapse and shock.

3. A careful examination should be made of all patients that are to undergo fever-heat therapy, and only doctors and nurses who are thoroughly conversant with this type of therapy should administer such treatment.

4. Photographs of different types of cabinets have been presented, with charts showing comparative fever and pulse curves.

5. Acute syphilis responds stubbornly to fever heat, whereas all types of chronic cases, when given a sufficient series of hyperpyrexia treatments demonstrate remarkable improvement in over 70 per cent of the cases.

6. Active chemotherapy is administered in all chronic syphilitic cases along with fever-heat treatments.

7. With electromagnetic induction in the production of fever-heat treatment, the syphilologist had added greatly to his armamentarium of therapeusis.

DISCUSSION

Rodney F. Atsatt, M. D. (1421 State Street, Santa Barbara).—The efficacy of the treatment of cerebrospinal syphilis through fever therapy produced by electrical means is so generally accepted as to need very little discussion. It is true that some authors still feel that there is an unexplainable malaria "toxin" which is specific for the treponema; but in most centers the artificial fevers are produced by electricity.

The problem is how to convert electricity into body heat or fever is a complicated one. Certain it is that several factors must be considered. The primary one is safety, as there must be no danger of burns either from contact or from eddy currents. The second factor is the ability to do exactly what you want in the process of heating; in other words facility, which will allow you to hold a predetermined temperature within a two-tenths degree range. The third factor is simplicity, which connotes the absence of all complicated mechanisms, and, fourth, the apparatus should be inexpensive.

Doctor Redewill's paper describes an ingenious mechanism for producing fever which depends upon the induction of an electromagnetic field. Judging it from our announced criteria, we think that perhaps the simple conditioned air cabinet may be superior and for these reasons. With a humidity of 70 per cent there will be little evaporation of perspiration, which means that droplets of salty water will be formed on the skin, and these will collect the eddy currents present in the electrical field, often to the discomfort and even danger to the patient. The facility of this mechanism is such that the flat plateau fever curves, where the temperature fluctuation is within a small range, are not often produced. (Incidentally, it may be noted that most conditioned air cabinets are operated at a temperature of from 120 to 125 degrees Fahrenheit, instead of 140 to 160 degrees as suggested.) In comparing the two devices as to simplicity and cost, the hot, moist-air cabinet needs nothing for its operation that cannot be purchased in an ordinary electrical store, while the Kimble method requires a source of electromagnetic induction currents necessitating a special mechanism.

However, entirely aside from this discussion as to method, Doctor Redewill is to be congratulated on a splendid piece of work on these Kahn-fast cases of syphilis. His reported results are excellent.

⁂

Norman N. Epstein, M. D. (450 Sutter Street, San Francisco).—The authors are to be complimented for their interesting contribution to the subject of artificial fever therapy. A study of the different physical methods which have been introduced for the production of an artificial fever during the past seven years shows a great tendency toward the adoption of simple procedures for this purpose. There is no definite proof to show that a fever which is induced by short-wave diathermy, or radiothermy or other electrical means such as the inductotherm, is safer or more beneficial than the artificial fever which is produced by placing the patient in an air-conditioned cabinet and electric blanket, or by wrapping him in woolen blankets plus the addition of an external source of heat.

In all of these modalities a most important factor in the production of the artificial fever is the prevention of radiation of heat from the body surface.

I wish to add my word of caution to those of the authors that great care must be exercised in the administration of artificial fever therapy. This attitude is expressed in practically every recent communication in the literature on this subject. Regardless of the method used to induce artificial fever certain serious reactions may occur, the most dangerous being a sudden rise in temperature to an extremely high point, such as from 107.5 to 110 degrees Fahrenheit. When this occurs death may ensue, although as a rule the immediate use of measures to reduce the temperature will avert this casualty. This reaction can be prevented only where the person conducting the treatment is highly trained and thoroughly experienced in the modality being used. Secondary rises in temperature several hours after the treatment had been discontinued may also occur and must be watched for.

The therapeutic results obtained by the authors in the treatment of cerebrospinal syphilis and Kahn-fast syphilis by the combined use of chemotherapy and artificial fever therapy are striking. There is no doubt but that artificial fever therapy is a most valuable adjunct in these types of syphilis, particularly neurosyphilis.

Space does not permit of further discussion, but in closing I wish to emphasize the fact that artificial fever therapy should be a hospital procedure under the direction of a highly trained personnel. Under these circumstances artificial fever may be employed safely, and is a valuable adjunct in the treatment of neurosyphilis.

⁂

Ross Moore, M. D. (1930 Wilshire Boulevard, Los Angeles).—Doctor Redewill's paper details three points which mark an advance in thinking concerning thermotherapy. First, he describes a method of treatment which appears to be safer than other electrofever methods; second, he shows that electrofever can be produced from within outward very easily without direct contact electrodes; third, the method he uses leaves the patient more comfortable than most other procedures—three valuable advances in treatment by means of artificial fever.

Since the paper is so well rounded out and complete, I shall confine myself to suggesting two additional points. The first of these relates to the use of fever treatment in late syphilis, including, under that term, all the sluggish manifestations of this disease. A considerable comparative experience leads me to conclude that electrically induced fever is not by any means the equal of malarial treatment. For, in my opinion, there is a certain biologic or specific reaction between plasmodium and spirochete, or between the products of their activity. This reaction does as much, perhaps even more than the coincident fever, to bring about recovery. Of course, there is room for sharp argument here.

The second point develops out of the more or less restricted type of cases which comes under my control, so-called "toxic cases" with sluggish appearing, nontransparent skins and other evidence of slowed or disturbed metabolism. Such cases frequently have a somewhat low-temperature range. In a large percentage of these cases a few fever treatments with mouth temperature, being pushed up only three or four degrees above starting point, are extremely helpful in clearing away toxic metabolites and eliminating symptoms. Such treatments are easily given, even in the home bathtub; and if properly supervised they are both devoid of danger to the patient and free from unpleasantness. I recommend a study of low fevers, as well as hyperpyrexias, to physicians who have among their patients examples of metabolic sluggishness and toxic metabolites.

CANCER CLINICS IN SMALL HOSPITALS*

By Zera E. Bolin, M.D.
San Francisco

Discussion *by Charles A. Dukes, M. D., Oakland; Gertrude Moore, M. D., Oakland; Orville N. Meland, M. D., Los Angeles.*

THE cancer situation in California is causing comment from the rest of the United States. According to statistics from the life insurance companies, the death rate from cancer in California is apparently rapidly increasing. The situation in San Francisco is especially alarming in that the death rate from cancer is one of the highest in the whole United States, there being probably only one city which exceeds San Francisco's death rate.

CANCER COMMISSION OF THE CALIFORNIA MEDICAL ASSOCIATION

This situation is being combated by the California Medical Association in various ways. Several years ago there was formed the Cancer Commission of the State Society. This Commission, under able leadership, has made considerable progress. The progress so far has been along the line of professional education. The Commission has sponsored conferences of pathologists and radiologists before each yearly meeting of the Association. It has collected, and published in book form, the consensus of over four hundred doctors in California dealing with cancer. It has sponsored cancer meetings in practically every county society.

THE GENERAL PRACTITIONER IS THE KEY MAN IN CANCER WORK

The need for this professional education is not as apparent at first sight as will be shown later. The number of cases of cancer seen yearly by the general practitioner in the smaller communities averages two a year. This number of cases of cancer does not allow the key man, the general practitioner, in the cancer situation to obtain a proper method of approach to diagnosis and treatment. The mental bewilderment of the man who first sees cancer is partly responsible for the unwarranted delay which occurs. In a large series of cases this delay averages five months before the patient seeks medical care and, strangely enough, it averages five months after the patient has sought medical care until adequate treatment is obtained. The cause of this delay is twofold. The patient who has been seeking medical care does not understand the nature and seriousness of the disease. The cause of the delay, after the physician sees the patient, is due to the inability of the doctor to decide, first, as to diagnosis and, second, as to treatment. Therefore, the doctor temporizes with the patient, and hopes against hope that the lesion is not cancer. The delay on the part of the patient can only be shortened by general public education; but it is not the purpose of this paper to discuss this phase. The delay after the patient has seen a physician can be materially changed by one of several means, the most important of which is professional education.

---

* From the Department of Pathology, Mary's Help Hospital, San Francisco.

Read before the Pathology and Bacteriology Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

EDUCATIONAL COURSES ON CANCER

The education of the physician in the natural history of cancer starts, of course, in the medical school. It would not be untruthful to say that there is no adequate course in cancer as a natural biologic phenomenon given in any medical school at the present time. The histology is given in the course on pathology. A few words about treatment are given by the surgeon and radiologist, but a comprehensive view is never afforded the student. The medical student in his intern year comes in contact with the actual handling of cancer cases, and this is his first chance to study cancer as it affects an individual patient. So the education of the physician should start in his medical school, and should continue throughout his intern and formative years. Adequate courses in cancer should be a part of the curriculum of every medical school.

The education of a nurse and her attitude toward cancer are of extreme importance. Schools of nursing should see that cancer is presented in the proper light as a preventable, curable disease in its early stages, and that late cancer can be treated so that the patient can live a fairly useful life.

The education of the hospital executives and the board of directors is of equal importance in order that adequate space, funds, and equipment may be supplied. The problem of making a hospital staff "cancer conscious" is not a hard one to solve. All of the elements for the diagnosis and treatment of cancer are available in practically every hospital. It is a question of coördination and use of facilities.

A HOSPITAL SHOULD HAVE A CANCER COMMITTEE

If the president of the staff will appoint a committee on cancer, the coördination can be started. The committee should consist of members of the various divisions of the staff treating cancer and, of course, the radiologist and pathologist. In every cancer committee, the pathologist is the key man. As the key man, the success or failure of the cancer clinic depends upon the pathologist.

The committee should organize, electing a chairman and a secretary. The secretary could easily be the intern on that particular service. The cancer committee then asks the approval of the staff to the proposition that all patients having tumors of any description be sent to the cancer committee for registration and diagnosis. If the patients are all clinic patients, this can be done without much difficulty. In some hospitals it will be practical for private patients to be also so referred to the cancer committee. An important distinction should be made as to treatment. In most hospitals it is preferable to have the patients registered, diagnosed and followed up, allowing the treatment to be given by the individual department from which the patient originates.

The cancer committee should have regular weekly meetings, and should report the scope of its work monthly at the staff meetings. The committee, in addition to seeing the patients for registration and diagnosis, should sponsor educational programs and report the result of all treatments given.

RECORDS OF CANCER PATIENTS

The records of such a committee may be in a very simple form. A small individual card for each patient should be made out, following an agreed upon system. The American College of Surgeons has forms which are available for use. The small card will include all pertinent data as to the patient's tumor, leaving the general examination to the department sending the patient. An index of patients should be kept by name and by disease, which would include a file of the parts involved and a file of the variety of tumor. An index of results of treatment and operations could be added.

FOLLOW-UP SERVICE

The follow-up of a patient is important. This can be done through the social service workers and through the nursing staff. The key man in the follow-up system is the secretary of the committee who should inform the patients of the time at which they are to report and supervise the social service.

The above scheme requires no additional funds. Each part of the scheme is taken from the facilities of the hospital now at hand. Funds, however, will come as soon as the staff and board of directors see the good work. These funds can be used for various purposes, but should be restricted to the employment of a paid secretary, if necessary, to buy supplies and to the hospitalization of early curative operative cancer.

EXPERIENCE IN MARY'S HELP HOSPITAL

The experience of the Cancer Committee in Mary's Help Hospital is illuminating. This is a small hospital of about 120 beds. It has an outpatients' clinic, averaging about one hundred visits daily. About three years ago the pathologist requested the president of the staff to appoint a cancer committee. This committee has been reappointed each year for the past three years, with additional members, so that now the committee has nine men. The committee comprises the pathologic, radiologic, and members of the medical surgical departments and of the various specialties. The committee has been recognized by the American College of Surgeons as a diagnostic cancer clinic.

For the first few months the attendance of the members of the committee was very scant, not averaging over three men. During the last year we have had an average attendance of over twenty physicians weekly. The new cases registered have risen weekly from one until, last year, we registered seven new cases weekly. There is an average attendance of patients of from twelve to fifteen weekly. The return visits account for most of this patient attendance. We find that we lose approximately 20 per cent of the patients registered.

The results of such a cancer committee are shown by the fact that in the three years we have seen over 350 tumor cases. We have educated, partly at least, fifty doctors. We have seen tumors of each part of the body from scalp to toenail. There is scarcely a tumor mentioned which has not been seen in our clinic. I feel that the committee will never be abolished as long as the physicians realize its need.

IN CONCLUSION

In conclusion, let me say that every hospital of one hundred beds or more needs such a clinic. The need is especially felt in the smaller communities. And this need can be filled by starting such a cancer clinic, when its educational facilities will be appreciated by everyone taking part in it.

490 Post Street.

DISCUSSION

Charles A. Dukes, M. D. (426 Seventeenth Street, Oakland).—I wish to congratulate Doctor Bolin on his timely comments on the cancer clinic in small hospitals. The California Medical Association and the American College of Surgeons have particularly sponsored this type of activity.

I am thoroughly convinced that the treatment of cancer is a group problem, but I do not fully agree with Doctor Bolin on the pathologist being the key man of the group, valuable as he is. The key man, if such a term could be used, is one who will devote his time and energy to the organization and create sufficient interest to keep the clinic in the position it deserves in the activities of the hospital.

We have found in our clinics at the Highland Hospital that the interest can very quickly dwindle if the organization becomes lax. Consequently, I believe that in selecting a chairman one should be given this important post who fully understands the hard work and faithful attendance required, and who will also appreciate that the clinic, to become a factor in the activities of the hospital, must be made interesting to all those who attend.

Doctor Bolin has emphasized the educational program in cancer and the importance of the general practitioner. His problem is the early diagnosis of cancer, and he must accept the responsibility also of the necessity of advising early treatment; also his attention must be called not only to prompt, but efficient treatment, and the close relationship between biopsy, diagnosis, and treatment.

Emphasis can also be given to Doctor Bolin's recommendation for complete records, a follow-up service, and the need for sufficient funds to carry out the important work that the cancer clinic represents.

⁂

Gertrude Moore, M. D. (2404 Broadway, Oakland).—It is admitted by all who are familiar with the problem that the most urgent present-day need in cancer control is education of the medical profession, to the end that the highest degree of accuracy may be attained in diagnosis, and that adequate treatment may be applied without delay. In spite of this crying need, we continue to neglect the only plan which will accomplish the desired end, namely, that of bringing patients in large numbers to groups of physicians for the clinical study of cancer. Doctor Bolin's figures clearly show that the average doctor in general practice sees too few cases in a lifetime to gain sufficient experience for the satisfactory treatment of malignant disease, and in his confusion delays treatment for long periods. If the general surgeon is to render an acceptable service in the treatment of cancer, he must be given the opportunity to gain experiences with many cases of varied character. This is one of the most important accomplishments of cancer committees and cancer commissions, for they offer the opportunity to see and examine a wide variety of neoplasms and to follow patients treated by acceptable methods to their completion. In the present-day cancer clinics this work is limited almost entirely to indigent patients who receive the attention of a group of specialists, while in contrast the average private patient has the unsupported opinion of a man of very limited experience in cancer work. The essayist very clearly brings out this phase of the problem when he says, "In some hospitals it will be practical for private patients to be also referred to the cancer committee," implying that this is far from the rule. And, too, he suggests that treatment be left entirely with the patient's physician. It is no doubt wise and expedient at present to proceed in this way, but the fact remains that the private patient suffers because of the necessity for this arrangement.

For more than six years I have been intimatey associated with group cancer work as a member of the Alameda County Cancer Commission, consisting of a group of specialists who care for Alameda County's indigent cancer cases. During this time we have studied about three thousand cases of cancer. It has become increasingly apparent to all of us that the best treatment can only be obtained after careful, and often repeated discussions by the entire group. Many of the physicians of this city, realizing the advantages of this work, have on occasions requested the Cancer Commission to review private patients for them. This, of course, is not possible in a county clinic, but it has perhaps prompted a move, at present on foot in one of our private hospitals, to establish a cancer committee somewhat along the line suggested by Doctor Bolin, but with perhaps a little bolder purpose, in that it is applied entirely to private patients, there being no free cases in this institution. It is an experiment and may fail for reasons that have been so frequently pointed out; but there is an encouraging, whole-hearted enthusiasm on the part of staff members. Time alone will tell whether or not such a plan can be put into practice among private patients. The move is entirely educational, prompted by the desire of those of us who have seen the benefits of group practice, as it has been applied to clinic cases, to extend these benefits to a wider circle of doctors and their patients. I would, therefore, like to add my appeal to that of Doctor Bolin, that all who are interested in the cancer problem aid in stimulating group-cancer study, to the end that advances in the diagnosis and treatment of this disease may keep pace with scientific advancement in other fields of medicine.

⁂

Orville N. Meland, M. D. (1407 South Hope Street, Los Angeles).—As we see it today, the cancer question is a matter of education. Despite the fact that surgery and radiation cure a large number of patients, the laity and some members of the profession are still pessimistic and feel that once cancer is diagnosed nothing can be done. This is true if the patient seeks advice in the terminal stages of the disease. The solution, therefore, is dependent on the dissemination of the true facts regarding early diagnosis and treatment. The Cancer Commission, recognizing the need for professional education, has been carrying out such a program with a measure of success. However, as Doctor Bolin says, this is only half the battle; it must be carried to hospital executives to make them cancer-conscious in the hospitals where they have control, and to nurses who, in our experience, are woefully ignorant of the course of cancer and its adequate treatment. It is surprising the number of people who question a nurse about their ills before seeing a physician. An enlightened nursing personnel may often get a skeptical patient started on the right track rather than being shunted into the hands of the irregular cults, who promise much but accomplish nothing.

Perhaps the best way to influence doctor and patient alike is through the cancer clinic established in the various hospitals. In public hospitals it is easy to make a rule that all cancer patients or suspected cancer patients must be seen by a board of physicians and surgeons who are interested in the diagnosis and treatment of cancer. In the private hospital such a rule would not work out, as it will interfere with the right of the individual doctor to practice as he sees fit. The younger men with limited experience will send patients for an opinion, but the older surgeons will not do so.

In order to get around this the members of the tumor clinic of the California Hospital are indexing all cancer patients that come to the hospital, and are instituting an adequate follow-up; from this the end-results of treatment may be computed. Then Doctor Maner presents the autopsy or operative material, discussing the diagnosis and treatment. This opens up the case for argument as to its proper handling, and why the treatment was or was not successful. Such a procedure will result in a slow but steady improvement in end-results.

Personally, I am not prepared to advocate cancer clinics in all small hospitals. While such a program is theoretically correct, the number of patients seen will be very small. To my mind, it seems much more logical to have clinics in a few large hospitals where patients may be sent and where outside physicians may see a variety of material. Too many small clinics with limited clinical material will result in lack of interest of the staff, but a few well-directed clinics will easily result in growth and progress.

FALLACIOUS TRENDS IN PSYCHIATRY*

By William Edler, M.D.
Pasadena

Discussion *by George Dock, M.D., Pasadena; Edward W. Twitchell, M.D., San Francisco; H. Douglas Eaton, M.D., Los Angeles.*

In the fundamental sciences, mathematics, physics, chemistry, etc., knowledge is admittedly known, unknown, or in a hypothetical or theoretical state. Wary, through the ages of experience, scientists apply rigid rules to test the truth or falsity of any conclusion, and to the speculative sphere are relegated such phenomena that do not come within the provable class. No emotional content enters the analysis, and negative results are recorded with the same indifference and given the same values as are the positive.

INHERITED METHODS OF APPROACH

How different in medicine! Here the trend is to know everything, to label maladies with a symptom nomenclature, hoping by a multiplicity of terms to conceal ignorance and sophistical reasoning. There is a historical background for this: the physician is a direct descendant of the ancient medicine man, whose diagnostic and therapeutic ability depended upon his theologic rather than his intellectual attainments. Since he was working through, and with both omniscient and omnipotent powers, and purported to be the direct agent of this dual force, it is evident that limitations of his capacity in any sphere were inevitably denied. The basic science man accumulated sufficient facts to discredit this imposter's power to interpret happenings, past, present or future, resulting in a divorcement from, and a fear of reconciliation with, his erstwhile associate.

On the other hand, our modern medical man still tends toward the occult, still pretends knowledge he does not possess, still heals by drug incantations and with the slogan *post hoc, ergo propter hoc* reverts back to his mystic ancestry. Smugly, his ignorance is masked by labels, terms and symbols: unknown diseases are called functional—uncured diseases are treated by substituting for the patient a laboratory symbol, and great satisfaction or disappointment is evidenced over the algebraic fluctuations from minus to positive signs. One must get laboratory improvement even though attended with clinical dissolution.

PSYCHIATRY'S HANDICAPS

If this be true in general medicine, how emphatically is it true of psychiatry! Some seven schools of diagnostic and therapeutic thought are represented at this time in the psychiatric field, ranging from the occultism of Christian Science, Oxfordism, Freudianism, and what not, to the fields of endocrinology, biochemistry, genetic, environmental, physiologic, and organic groups. By a six-to-one vote each would be eliminated from the field were a poll taken to determine the scientific status of any one of the particular schools of thought, each group uniting to vote the other wrong. The crux of the problem is that no standard has been or is established by organized medicine which would promote criteria whereby fallacies, theories and downright quackery could be controlled by exacting scientific diagnostic, and therapeutic standards applied to psychiatry as it tends to be applied to internal medicine and surgery. Recovery from an illness cannot be used as an argument for the merit of the treatment; and only by hundreds of controls can any scientific evaluation be placed on the efficacy of any drug or any other treatment, be it in the so-called mental sphere or the physical realm.

It is the mental category that primarily concerns us. We use the term glibly, but who is going to define it. If we mean by mental a resultant thought process due to interactivity of certain brain cells that culminates in sensory reaction with ultimate muscular movement or absence of movement, then we have at least a relative criterion for conduct—so-called normal or abnormal. After all, basically, we are concerned with sensation. This is particularly stressed, because it leads us to the definite field of psychogenetic etiology and a school of psychiatry that has been popularized with the medical profession and particularly with the lay public. Disregarding the controversial concepts among leading exponents of this particular school, let us attempt a comparative study of so-called mental physiopathology with physical physiopathology and see where we land. We are asked to believe that maladjustment—*i. e.*, painful thought experience—is the cause of bizarre conduct, *i. e.,* maladjustment; or, in other words, that psychic pain, the resultant of cerebral dysfunction, is the cause of psychic pain attended with pathologic muscular activity (abnormal conduct), which in turn we designate a psychosis. This is hardly logical. As illogical as propounding that albumin in a urine specimen is the cause of nephritis. When we approach such psychotic phenomena as hallucinations and delusions, detailed argument is advanced by our theorists to show psychic defensive mechanisms that produce these subjective effects, forgetting, by your leave, the simple fact that one-fiftieth of a grain of hyoscin or a few ounces of alcohol will produce the same result.

---

* Read before the Neuropsychiatry Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

THE PSYCHOSES

When we consider that the psychoses are a tremendous liability on the social and economic structure, I believe it is time for organized medicine to include in its department of "new and unofficial remedies" the various therapeutic claims made by organized groups of psychic healers. Newspapers have been used where Freudian columnists have answered the wails of the afflicted whom they had never seen, with, at least in one instance to my knowledge, the charlatanry of the patent-medicine quack, the advice to "read my book," or Mae West-like, "come up and see me some time."

VOLUMES ON MENTAL DISEASE—FOR LAYMEN

What would the reaction of the internal section of this society be to an internist who wrote a treatise for the lay public on "How to treat your kidney disease." Yet book-shelves are cluttered up with volumes of advice to laymen on mental disease, a problem far more complicated, much more difficult to interpret than the aforementioned malady. We permit it for one reason, and that is that we are still hazy in our notion that mental disease is something distinct from physical reality. We are still mesmerists, Christian Scientists, Oxfordists, or whatnots, following the principle that in some way, we do not know how, the patient is to blame for a condition that our ignorance cannot fathom. If we do not know, since we are the descendants of an all-knowing clan, certainly the patient must still be in demoniac possession.

IN CONCLUSION

In conclusion, this paper is a plea for the application to psychiatry of the same standards that are applied to any other branch of medicine, or, for that matter, to any other science. Let us have our psychiatric hypotheses and theories, and fight them out in our meetings. Let us outlaw any physician who goes to the laity with psychiatric cures, just as we discipline the surgeon or the internist who violates the decencies of his ethical code.

Finally, can we not gain—those of us who deal with the mentally afflicted—the laity's confidence and esteem to a greater degree by swallowing our pride, gritting our teeth, and answering mother's question, "What on earth has caused Mary's breakdown, doctor?" by the simple, honest reply, "I do not know."

Some day, somewhere, in the laboratory, something will develop that, over night perchance, will expunge from the medical literature the fantastic interpretation of the so-called functional psychoses and substitute therefor the factual findings of a persistent and enterprising research man.

595 East Colorado Street.

DISCUSSION

George Dock, M. D. (94 North Madison Avenue, Pasadena).—Doctor Edler has given us a concise and accurate statement of the past and present bases of thinking and acting in medicine. Perhaps he is correct in thinking progress in psychiatry is less satisfactory than that in other departments of medicine and surgery; but, on the other hand, it may be that he overrates the situation in some of these other branches. His suggestions for improvement are interesting. An excellent one is to carry on greater activity in the discussion of hypotheses and theories—"fight it out in meetings." The idea of more active discussions might well be applied in some other sections beside that of psychiatry. A more questionable suggestion is the idea of outlawing physicians who propagate psychiatric cures and publish books for self-treatment. In doing this, is there not a new danger in giving the outlaw all the glamor of a martyr and publicity? The suggestion that physicians should avoid mystification and give honest replies, such as "I don't know," is good as far as it goes. But in the example stated, should not the physician go on and indicate to Mary's mother and to Mary, if possible, the knowledge and resources he has that might be applied to the case? Doctor Edler's whole argument is very fine for experts, but can it be applied to a population that destroys crops in order to make food more accessible, that spends to save, that urges pulling one's self up by bootstraps, etc.? Coming especially to psychiatry, how can we apply the methods of a medical society to a population fed daily with columns of the antics of a poor dement with alcoholism, who is written up as a "prankster" or "funster," when he needed all the best efforts of nurses and physicians? Such a man gets more attention from the public and probably influences more minds than a Millikan or an H. G. Wells. At all events, we physicians can cultivate our own gardens, direct patients and the public generally to honest experts, and so in time raise the level of accurate thought and practice.

⁂

Edward W. Twitchell, M. D. (909 Hyde Street, San Francisco).—One may readily agree with some of Doctor Edler's propositions, if not, however, with all of them, except in part.

It is quite true that medicine is not an exact science. Present-day discussions of the physicists would lead one to believe that there is no such thing as an exact science, but medicine never has made any pretense to being exact, and for that matter it has always been pretty freely admitted that medicine was an art in a very large part and only gradually becoming a science.

As to the psychiatrists being the worst of the lot, it may be advanced that they have been too modest in self-defense. It is true that hospitals for the insane all over the land are filled with patients whom psychiatry is not curing. There are also an enormous number of the tuberculous and cancerous, and those with hypertension and those suffering from nephritis or from hepatic cirrhosis, and from leukemia and a long list of other things belonging to the physician and surgeon which are not being cured any better than the psychiatrists are curing their patients. The trouble with the psychiatrist's patient is that he is so exceedingly obvious. He cannot go about the streets without attracting attention, as can so many of those having the diseases above mentioned.

Therapy in psychiatry is said to be ineffectual. It is unfortunately true, and one is inclined to agree with Ross when he says that psychoses get well of themselves, if they do at all, not by reason of what the physician has done; but he also says that the psychoneuroses can be cured, and the psychoneuroses form a very large part of psychiatric practice, and to the psychiatrists belong the credit of the great advance in the treatment of general paresis. Mental mechanisms are still a woefully dark field, and there is no school which can at present claim to have solved this problem.

When it comes to governmental control of psychic healers, which seems to be advocated in Doctor Edler's paper, that is treading on very, very dangerous ground. One is apt to get mixed up in a religious controversy for one thing, and even if one does not, how can a state which cannot control automobile or liquor traffic control psychic healers?

We are still empirics and shall be for a long time to come; but we are measurably better off than our grandfathers and far more prone to confess our ignorance frankly and freely than were our grandfathers.

⁂

H. Douglas Eaton, M. D. (1136 West Sixth Street, Los Angeles). — Psychiatry has been slower to emerge from the clouds of ignorance and superstition than other branches of medicine. While Hippocrates clearly recognized mental disorder as a disease due to physical causes, many factors combined to retard the development of a truly scientific viewpoint in regard to the psychoses. In fact, it was not until recently that much was accomplished along these lines.

The present century has seen definite progress in the scientific approach to psychiatric problems, even though there is still room for great improvement. Twenty-five years ago the percentage of "functional" psychoses made up 90 to 95 per cent of the total. Today 30 to 40 per cent of psychiatric cases are recognized as due to structural or organic changes. With the growth of biochemistry and the allied sciences it seems reasonable to expect that the "purely functional" psychosis will gradually vanish. Such a result, as Doctor Edler points out, will only be attained as the result of applying the same rigid rules of investigation as prevail in any science. No speculative or purely subjective theorizing will yield satisfactory results.

Many factors still remain to handicap the cultivation of a truly scientific viewpoint in psychiatry. For example, in many states, including our own, the law places the final diagnosis of insanity in the hands of a jury of laymen; yet even the law would not expect a lay jury to diagnose a case of pernicious anemia or appendicitis. Backed by this legal approval, many of the laity, especially the poorly educated and ignorant, consider that psychiatric problems—actually the most difficult of medical situations—are well within their powers to diagnose and treat. This generally prevailing lay attitude complicates greatly the proper medical care of the psychoses.

Because of the lack of scientific evidence, faddists within and without the medical profession have originated this or that theory to explain mental disease and have broadcast these theories to receptive audiences. Practitioners of the most popular fad within the profession have never published any adequate statistical studies of their therapeutic results, and its exponents usually explain any disagreement with their methods as due to the presence of a hidden disorder in the one who disagrees with them: if you do not believe as I do, then there is something wrong with you! Surely, such lack of the ordinarily accepted rules of scientific research stands in the way of scientific advancement.

Articles on psychiatric subjects by so-called experts, both lay and medical, flood our magazines and the daily press. Radio experts solve psychiatric problems and give advice freely over the air, with the result that those of us who are dealing daily with psychiatric cases must spend a large percentage of our time removing misconceptions before we can establish adequate therapy.

Psychiatry has been further handicapped by a tendency to become overly involved in terminology and classification. This tendency is fortunately subsiding, and we are learning to approach each case as an individual problem, realizing that only through a complete gathering and evaluation of all factual data can we hope to advance psychiatric knowledge and therapy.

THERAPEUTIC SCOPE OF CHIROPRACTIC: A LEGAL BRIEF*

No. 257362

IN THE SUPERIOR COURT OF THE STATE OF CALIFORNIA
IN AND FOR THE CITY AND COUNTY OF
SAN FRANCISCO

In the Matter of the Application of M. James McGranaghan, for Declaratory Relief, Plaintiff, vs. Dora Berger, Intervenor and Defendant, vs. Roy B. Labachotte, Intervenor and Defendant, vs. The People of the State of California, Intervenor.

BRIEF OF INTERVENOR, THE PEOPLE OF THE STATE OF CALIFORNIA

STATEMENT OF QUESTIONS INVOLVED

In the matter at bar the petitioner sought a declaration of his rights and duties under a license to practice chiropractic claimed to be issued pursuant to the provisions of the Chiropractic Act. He alleges graduation from a chiropractic school, but does not allege graduation from a legally incorporated chiropractic school or college, an essential under Section 8 of the Chiropractic Act, Statutes of 1923, page lxxxviii. The petition alleges, however, that he is licensed to practice chiropractic, alleges a conflict exists between persons licensed under the provisions of the Chiropractic Act and persons licensed under the provisions of the Medical Practice Act, Statutes of 1913, Chapter 354, as amended, and licensed chiropractors; and that he is in constant danger of prosecution under the provisions of the Medical Practice Act should he render services in excess of his license, and that he is likewise in a position of jeopardy should a civil action be brought against him for rendering services in excess of his authorized practice.

In paragraph 5 he seeks a construction of Section 7 of the Chiropractic Act to prevent, as he states, "the continued conflict and controversy now existing." He sets forth Section 7 of said Chiropractic Act, which reads as follows:

> Sec. 7. One form of certificate shall be issued by the board of chiropractic examiners, which said certificate shall be designated "License to practice chiropractic," which license shall authorize the holder thereof to practice chiropractic in the State of California as taught in chiropractic schools or colleges; and, also, to use all necessary mechanical, and hygienic and sanitary measures incident to the care of the body, but shall not authorize the practice of medicine, surgery, osteopathy, dentistry or optometry, nor the use of any drug or medicine now or hereafter included in materia medica.

and alleges that the college of which he is a graduate now teaches, and at the time of the adoption of the Chiropractic Act and prior thereto, taught the following enumerated subjects:

> Anatomy, embryology, physiology, chemistry, toxicology, histology, pathology, neurology, bacteriology, physical diagnosis, laboratory diagnosis, palpation or spinal diagnosis, nerve tracing, chiropractic technique, symptomatology, special technique including replacing shoulder, hip, rib and foot subluxations and dislocations, obstetrics, gynecology, pediatrics, first aid and minor surgery, terminology, hygiene and sanitation, treatment of diseases of the eye, ear, nose and throat, dietetics, psychiatry, x-ray, jurisprudence, mechanotherapy and massage, medical gymnastics, hydrotherapy, colonic therapy, physio-therapy, electro-therapy, photo-therapy, and practice building.

Paragraph VII recites that all of these enumerated subjects and other additional measures are, and were at the time of and prior to the adoption of the Chiropractic Act, taught as *chiropractic* in other chiropractic schools and colleges.

Paragraph VIII of the petition improperly alleges that the District Court of Appeal in the case of *Evans* vs. *McGranaghan*, construed Section 7 of the Chiropractic Act "as authorizing license holders thereunder to practice chiropractic and to use all necessary mechanical hygienic and sanitary measures taught as chiropractic in chiropractic schools and colleges,

---

* See also editorial comment concerning this case, printed on page 380 of this issue. The Court Opinion is printed on page 419 of this issue.

> "together with any other such necessary mechanical, hygienic and sanitary measures the use of which would not constitute the practice of medicine, surgery, osteopathy, dentistry or optometry, nor involve the use of any drug or medicine now or hereafter included in materia medica."

It is obvious that if the case of *Evans* vs. *McGranaghan* construed what this pleading alleges was construed it would be unnecessary for the petitioner to ask this court to make a finding as to what was there decided.

In said paragraph VIII it is alleged that the term "practice of medicine, or surgery" is indefinite and uncertain, subject to two or more contrary and conflicting interpretations.

By reason of the uncertainty of petitioner and his danger of criminal prosecution and liability for negligence as a result of what petitioner calls "contrary and conflicting interpretations" of the term "practice of medicine, or surgery," it is, in paragraph IX of said petition, alleged that this court should grant him declaratory relief to determine the interpretation of said term "practice of medicine, or surgery," as used in the Chiropractic Act.

Petitioner also seeks declaration of his rights and duties as a license holder under the provisions of the Chiropractic Act and prays for certain stated relief.

To the petition filed by McGranaghan one Dora Berger intervened and alleged chiropractic licensure in California, an adverse interest to petitioner, the possibility of her scope of practice being affected by the proceeding and the fact that no trial thereof had occurred.

She admitted that all of the subjects or measures set forth in paragraph VI of the petition were, at the time of the filing of her complaint in intervention, taught, and previous to the enactment of the Chiropractic Act had been taught, in chiropractic schools and colleges. She denied that any of the subjects or measures are authorized to, or within the practice of a chiropractic licentiate in California except "palpation or spinal diagnosis, nerve tracing, chiropractic technique, x-ray, hygiene and sanitation." She alleged that the remainder of the subjects referred to in said paragraphs were exclusively within the scope of practice of a drugless practitioner or physician and surgeon, both licensed pursuant to the provisions of the Medical Practice Act, and that the practice of such subjects was not authorized to a chiropractic licentiate, was beyond the scope of chiropractic practice and was detrimental to her practice and to her rights. Whereupon, she asked for an interpretation of the Chiropractic Act as not authorizing the use of such subjects and measures.

Based upon certain statements in the case of *Brix* vs. *Peoples Mutual Life Ins. Co.*, 18 Pac. (2d) 103, to wit: the People of the State of California asked permission to, and were granted permission to intervene in said proceeding. The state's theory in so doing was based upon the fact that all licenses granted to practice any form of the healing arts spring from the right of the people to protection from being mistreated or misled by incompetent or unscrupulous licentiates. (*State* vs. *Armstrong* (Idaho), 225 Pac. 491.)

It was and is our view that the individual members of society are entitled to know just exactly how far a person holding a qualified license may prescribe or render treatment. As, for example, no one would seriously contend that a dentist has the right to remove a brain tumor.

The people's intervention admitted the existence of a conflict as to the scope of practice authorized chiropractors, denied the existence of an actual controversy between those licensed under the Medical Practice Act and those licensed under the Chiropractic Act, and alleged the existence of actual controversies between certain persons licensed pursuant to each of said acts. The people's intervention admitted that the petitioner, McGranaghan, was in constant danger of criminal prosecution for rendering services in excess of his authorized practice, as well as admitted that his position would be one of great danger in the event of a civil action for negligence in the use of any measure outside his authorized practice.

The propriety of an interpretation of Section 7 of the Chiropractic Act was also admitted. Paragraph V of the people's answer in intervention denied that the National College of Chiropractic, from which petitioner alleged graduation, taught as chiropractic any of the subjects enumerated in paragraph VI of petitioner's complaint, except "palpation or spinal diagnosis, nerve tracing and chiropractic technique."

Our answer denied that the expression "practice of medicine and surgery" is now or was in the year 1922 (the year the chiropractic initiative was enacted) indefinite or uncertain or subject to two or more contrary and conflicting interpretations.

The people likewise traversed the answer in intervention filed by Dora Berger, though agreeing in the main therewith. We alleged, however, that certain other licentiates than those enumerated by her could do some of the things which she alleged could be done only by a physician and surgeon or a drugless practitioner. As for example, that chiropodists and midwives might perform certain of said acts.

Thereafter the people made further answer to the petitions of McGranaghan and Berger and sought *affirmative relief*. Our allegations were, briefly, that chiropractors might engage in palpation, spinal diagnosis, nerve tracing, chiropractic technique, chiropractic hygiene and chiropractic sanitary measures, but could not engage in any other method of treating the sick or afflicted. We asked that this court determine:

> 1. What was chiropractic as taught in chiropractic schools or colleges at the time of the adoption of said Chiropractic Initiative Act?
>
> 2. What necessary mechanical, and hygienic and sanitary measures incident to the care of the body, if any, may be used by the holder of a license to practice chiropractic in the State of California?
>
> 3. What, if any, were, in 1922 or thereafter, the mechanical, and hygienic and sanitary measures incident to the care of the body which are not included within the practice of medicine, surgery, osteopathy, dentistry or optometry, or which did not involve the use of any drug or medicine included in materia medica?
>
> 4. That all methods of treatment, save and except those which are chiropractic within the purview of the Chiropractic Initiative Act of California, constitute the practice of medicine, surgery, osteopathy, dentistry or optometry.

A fourth intervention was filed by Roy B. Labachotte, a chiropractic licentiate, who alleged that the doing of all of the things objected to by the State were not chiropractic and were not, prior to or after the adoption of the Chiropractic Act, taught as such, and that the practice of chiropractic consisted solely and not otherwise in:

> the adjustment of subluxations or misalignments of the segments of the spine when such subluxations or misalignments cause occlusions of nerves and interference with the transmission of nerve force at or within the spinal column, together with necessary mechanical and hygienic and sanitary measures incident to the care of the body in said practice of chiropractic.

Labachotte further alleged that until Section 7 of the Chiropractic Act is interpreted he and others would continue to practice beyond the lawful scope of practice under the Chiropractic Act, and prayed that the petitioner, McGranaghan, be denied the relief sought, and that he, the intervenor, have judgment construing Section 7 in accordance with the allegations of paragraph IV of his complaint in intervention.

RELATIVE TO THE RELIEF SOUGHT

Whether an application for declaratory relief is proper, is questionable. This was pointed out to the court at the commencement of this proceeding by the intervenor, People of the State of California. . . .

IS CHIROPRACTIC SOMETHING DEFINITE?

The above, we believe, sets forth the issues before this court. We, therefore, seek primarily to ascertain *"What is Chiropractic?"* In approaching the solution to the question we are not bound solely by the language used in *Section 7* of the Chiropractic Act. According to the following cases the Act must be construed as a whole so as to promote and not defeat the general purposes and policy of the law. . . .

We do *not* contend that the entire Act is unconstitutional and that the approximately twenty-eight hundred chiropractors in California are without the right to practice chiropractic. We contend that the Act is constitutional and that persons licensed pursuant thereto can practice *chiropractic* (whatever chiropractic is), but we insist that a person licensed under the Act can do no more than practice chiropractic, a definite and specific branch of the healing arts. . . .

Section 7 of the Act provides:

> One form of certificate shall be issued by the board of chiropractic examiners, which said certificate shall be designated "License to practice chiropractic," which license shall authorize the holder thereof to practice chiropractic in the State of California as taught in chiropractic schools or colleges; and, also, to use all necessary mechanical, and hygienic and sanitary measures incident to the care of the body, but shall not authorize the practice of medicine, surgery, osteopathy, dentistry or optometry, nor the use of any drug or medicine now or hereafter included in materia medica.

We urge that the prohibitory language contained in Section 7 of the *Chiropractic Act* means exactly what it says. By way of mandate it states a license to practice chiropractic

> *shall not authorize* the practice of medicine, surgery, osteopathy, dentistry or optometry, nor the use of any drug or medicine now or hereafter included in materia medica.

A legal mandate is stronger than a proviso and the latter is held in this state to be a covenant and condition precedent to the right to be exercised. . . .

DEFINITIONS OF PROHIBITED PRACTICES

Medicine

Section 17 of the Medical Practice Act provides:

> Any person who shall practice or attempt to practice, or who advertises or holds himself out as practicing, any system or mode of treating the sick or afflicted in this state, or who shall diagnose, treat, operate for or prescribe for any ailment, blemish, deformity, disease, disfigurement, disorder, injury, or other mental or physical condition of any person, without having at the time of so doing a valid, unrevoked certificate as provided in this act, or who shall in any sign or in any advertisement use the word "doctor," the letters or prefix "Dr.," the letters "M.D.," or any other term or letters indicating or implying that he is a doctor, physician and surgeon, physician, surgeon or practitioner, under the terms of this or any other act, or that he is entitled to practice hereunder, or under any other law, * * * shall be guilty of a misdemeanor and upon conviction thereof shall be punished as designated in this act, * * *

From this it would appear that the Medical Practice Act covers *any and all* systems or modes of treating the sick or afflicted. Hence it may be said that the practice of medicine is and was in 1922 defined by statute.

This is further indicated by the language of Section 8 of the Medical Practice Act, which provides for the issuance of various certificates. The section provides in part that:

> * * * a certificate authorizing the holder thereof to use drugs or what are known as medical preparations in or upon human beings and to sever or penetrate the tissues of human beings and to use any and all other methods in the treatment of diseases, injuries, deformities or other physical or mental conditions, which certificate shall be designated "physician and surgeon certificate"; * * *.

How the expression "any and all" methods in the treatment of diseases came into the Medical Practice Act shows the statutory development of medicine and surgery in this State. In the case of *Ex Parte Greenall,* 153 Cal. 767, determined in June, 1908, the petitioner sought a writ of *habeas corpus* after conviction upon a complaint charging violation of the Statutes of 1907, page 252, being entitled:

> An act for the regulation of the practice of medicine and surgery, osteopathy, and other systems or modes of treating the sick or afflicted, in the State of California, and for the appointment of a board of medical examiners in the matter of said regulation.

It should be stated that the writ was granted and the petitioner discharged solely because of the language of the complaint. The Court pointed out the history of the statutes regulating the practice of medicine and surgery and state: . . .

From this it is evident that the Act of 1901 defined what constituted the practice of medicine specifically; that the Statutes of 1907 had as broad a meaning as had the Act of 1901 and that the present Act of 1913 is more broad than either of the said acts for the reason that it includes *any and all* methods of treating the sick or afflicted. It may, hence, be said that the Legislature has defined the practice of medicine.

We must follow what our statute defines as the practice of medicine. (*Foo Lung* vs. *State,* 84 Ark. 477; 106 S. W. 946.)

If evidence be needed as to what constitutes the practice of medicine, the testimony of Dr. Ebright, Dr. Rixford, Dr. McKenny, Dr. Langnecker, Dr. Morrell, Dr. Vecki, and Dr. Ruggles certainly covers the situation. Their testimony is to the same effect as is our law and as are the adjudicated cases. In other words, every method that can be used for the alleviation of suffering, the prevention of disease, the correction of a physical or mental condition, is included in the sphere of medicine. (*Commonwealth* vs. *Jewelle,* 199 Mass. 588; 85 N. E. 858.)

Surgery

Surgery is included in our statutory definition. In Section 8 of the Medical Practice Act is the expression "to sever or penetrate the tissues of human beings and to use any and all other methods in the treatment of diseases, injuries, deformities, or other physical . . . conditions."

It may likewise be said to be included in Section 17 of the last mentioned act, where an unlicensed person is prohibited from "operating for any ailment, blemish, deformity, disease, disfigurement, disorder, injury, or other mental or physical condition." A type of surgery is included in the art of chiropody. Section 8 of the Medical Practice Act permits certain surgical treatment to be given by a chiropodist, to wit: the surgical treatment of abnormal nails, corns, callosities, bunions and other minor foot ailments not involving the bony structure, and does not confer the right of amputation of toes or joints thereof, except as hereinbefore specified, or any portion of the foot or the severing of any tendon or the use of any anesthetic other than local. Hence it may be said that all forms of surgery are defined by the Medical Practice Act.

The testimony of the experts called on behalf of the State is entirely in accord with the definition of surgery in the Medical Practice Act. Doctor Rixford, it will be recalled, testified that the so-called manipulation of the vertebra of the spine was a surgical operation, although no cutting was done therein.

Osteopathy

The practice of "osteopathy" as that term is used in the Initiative Act, is prohibited to a chiropractor. It is to be noted that the Chiropractic Act does not say that a licensed chiropractor is not to do the things which an osteopath is entitled to do under the law, but says such a licentiate shall not practice osteopathy. Because of the fact that counsel for the intervenor, Labachotte, disagreed in oral argument with counsel for the State as to the meaning of the word "osteopathy," we make the above distinction, because we believe that the people, in voting for the chiropractic initiative, intended to refer to the science of osteopathy rather than to the rights of an osteopath under the law. We concede that the legislature might grant rights to persons holding particular licensure, which could be either in excess or less than such persons were taught. As an example we concede that the legislature could—though we doubt that it would—permit chiropodists to engage in unlimited surgery upon a human being below the ankle. Should it do so the legislature would not change the definition of the word "chiropody," but would merely grant increased rights or privileges to a chiropodist.

It is, therefore, our contention that the expression "osteopathy" used in Section 7 of the chiropractic initiative means osteopathy as the same was theretofore known and in this connection we cite *In re Nowak,* 184 Cal. 701, to the effect that expressions which have theretofore been construed by the Supreme Court and which are later used in an initiative or statutory enactment must receive the interpretation theretofore approved.

In the following cases osteopathy has been defined: . . .

Dentistry

Dentistry is and was defined in the Dental Law of California. It is defined in Section 11 as follows:

> A person practices dentistry within the meaning of this act who (1) by card, circular, pamphlet, newspaper or in any other way advertises himself or represents himself to be a dentist, or (2) for a fee, salary or reward, paid directly or indirectly either to himself or to some other person, performs, or offers to perform, an operation of any kind, or treats diseases or lesions of the human teeth, alveolar process, gums or jaws, or corrects malimposed positions thereof, or (3) in any way indicates that he will perform by himself or his agents or servants any operation upon the human teeth, alveolar process, gums or jaws, or in any way indicates that he will construct, alter, repair, or sell any bridge, crown, denture or other prosthetic appliance or orthodontic appliance, or (4) makes, or offers to make, an examination of, with the intent to perform or cause to be performed any operation on, the human teeth, alveolar process, gums or jaws, or (5) manages or conducts as manager, proprietor, conductor, lessor, or otherwise a place where dental operations are performed. The following practices, acts and operations, however, are exempt from the operation of this act: (a) The practice of oral surgery by a licensed physician, etc.

Optometry

Optometry is and was defined by statute. Chapter 598 of the Statutes of 1913 (this section has never been amended):

> Section 2. The practice of optometry is hereby defined to be the employment of any means other than the use of drugs for the measurement of the powers or range of human vision for the determination of the accommodative and refractive states of the human eye or the scope of its functions in general or the adaptation of lenses or frames for the aid thereof.

Drugs or Medicines

The use of those drugs or medicines which were in 1922 or should be thereafter included in materia medica is prohibited.

Materia medica is defined in the case of *Millsap* vs. *Alderson*, 63 Cal. App. 518 (August, 1923), as:

> the substances employed as remedial agents.

Pursuant to Section 1875 of the Code of Civil Procedure, this court has authority to consult such standard works as the United States Pharmacopoeia, National Formulary, and the booklet which is issued by the American Medical Association between the publications of the first named compilations and which is known as "New and Nonofficial Remedies."

From this it is evident that no drugs or medicines can be used by a chiropractor.

DEFINITION OF CHIROPRACTIC

Because of the expression "any and all" other methods in the treatment of diseases, injuries, etc., which is used in Section 8 of the Medical Practice Act, we contended in oral argument that the practice of medicine covered every field appertaining to the healing arts and included every branch thereof. We directed, for the sake of a simple example, the court's attention to a pie and stated that the field of medicine included the pie in its entirety and that other forms of the healing arts covered segments thereof.

Before the enactment of the Chiropractic Act, persons practicing "chiropractic" without being licensed to practice medicine and surgery or without licensure as drugless physicians were guilty of the offense of practicing medicine without a license. (*People* vs. *Vermillion*, 30 Cal. App. 417; *People* vs. *Oakley*, 30 Cal. App. 519.)

After the enactment of the Chiropractic Act, a person practicing "chiropractic" without being licensed to practice medicine and surgery, drugless practice or chiropractic was guilty of the offense of practicing medicine without a license. Of a consequence, chiropractic must still be included in the field of medicine.

That our contention is sound has been determined by the District Court of Appeal of this State in *People* vs. *Mills*, 74 Cal. App. 353 (September, 1925), in which case a hearing by the Supreme Court was denied. Therein an individual was charged with the practice of medicine without a license. . . .

The first time we find reference to the expression "chiropractic" in the courts of this State is in the case entitled *In re Greenall*, 153 Cal. 767. This case was before our Supreme Court in 1908. . . .

We appreciate that the Supreme Court did not in such case define chiropractic. It did, however, state what the petitioner contended was chiropractic and, historically, such case is important and may be consulted. . . .

The Chiropractic Act prohibits a licentiate thereunder from practicing medicine, surgery, osteopathy, dentistry or optometry and prohibits the use by said licentiate of any drug or medicine. As chiropractic is included in the field of medicine a strict construction of this language would keep a chiropractor from doing anything under the terms of his license.

It is a cardinal rule of statutory construction, however, that laws must be so interpreted as to give effect thereto, if such an interpretation is possible. Accordingly, we contend that the following *dicta* from the case of *Evans* vs. *McGranaghan*, 80 C. A. D. 866, applies:

> As we construe section 7 of the Chiropractic Act it authorizes the licenseholder to practice chiropractic * * * regardless of whether such practice would have been construed as the practice of medicine, surgery, osteopathy, dentistry or optometry prior to the enactment of the Chiropractic Act.

In other words, we believe that the chiropractor can practice chiropractic, a limited segment of the field of medicine, but cannot cross the border line from that segment into the forbidden field. Again, the classical example of the pie and the piece thereof. A chiropractor may go from one side of the cut piece of pie to the other, but he cannot cross over into the remaining major segment.

To avoid an absurd interpretation we are forced to conclude that the prohibitory provisions of Section 7 of the Chiropractic Act do not mean exactly what they say. Of necessity there must be a departure from the literal construction of said section. Were this not so, a licensed chiropractor could do nothing by virtue of his license.

By departing from the literal construction we find that a chiropractor can practice chiropractic in so far as chiropractic is included in any of the prohibited practices, but may not pass from the realm of pure chiropractic into the realm of medicine, surgery, etc. Cases approving this doctrine are: . . .

Indeed, in the case of *People of the State of California, etc.* vs. *Steele*, decided in the Superior Court of this State, in the county of Santa Clara, and reversed only because it was tried on a nuisance theory, the court in its opinion stated: . . .

> Without attempting to unduly prolong a discussion of the essential character of chiropractic theory, it may be stated, generally, that the science or art of chiropractic is found in these general propositions: that in the brain of the human animal is the point of control of an innate intelligence which sends its controlling forces by way of the spinal cord through the spinal column and then through the various nerve trunks emitting from the spinal cord and passing through the intervertebral foramina to nerve branches ramifying to all parts of the body, through the perfect functioning of which, health is maintained, but through interference with the transmission of those innate forces through or over the nerve, disease is produced; that owing to the spinal column being the only segmented structure of bone through which these nerve trunks pass and the possibility of displacement of its segments changing the size and shape of the intervertebral foramina, subluxation occur and there offer interference with the transmission of innate forces directly or indirectly; that all disease is thus traceable to impingements of nerve tissue in the spinal column. Chiropractic claims the knowledge of this all-inclusive cause of disease and the ability to adjust and correct these displacements of the segments of the spinal column, thereby removing interference with the transmission of the innate forces. It claims that such adjustment does not add any material forces to the body, but allows the innate to restore to normal what it would have had, had there been no interference. In this manner, it is claimed, health is restored.
>
> It will thus be observed that the theory, science or art of chiropractic is quite definitely circumscribed in its character, scope and practice. * * *

INTERPRETATION OF OTHER PORTIONS OF SECTION 7

Having disposed of the practices prohibited to a person holding a license to practice chiropractic, we approach the clause

> and, also, to use all necessary mechanical, and hygienic and sanitary measures incident to the care of the body.

We note that a semicolon precedes the expression "and" which introduces the portion of the sentence here considered. If the effect of the semicolon is to shut off from the preceding portion of Section 7 the thought there contained, obviously a person with a license to practice chiropractic is granted an extra privilege, the privilege being to use all necessary mechanical, and hygienic and sanitary measures incident to the care of the body which do not transgress the field of medicine.

Because, however, the testimony in this case shows that all mechanical and hygienic and sanitary measures "indicated as necessary" in a particular case are included in the medical field, it is our view that this clause must be read in the light of the antecedent and subsequent thoughts. The antecedent thought is that a licentiate may practice chiropractic, and from this we conclude that a licentiate may use necessary *chiropractic mechanical*, and *chiropractic hygienic*, and *chiropractic sanitary* measures incident to the care of the body as long as these measures do not enter the prohibited fields.

It is a settled rule of statutory interpretation that

> qualifying words and phrases, grammatically and legally, where no contrary intention appears, refer solely to the last antecedent. A proviso is construed to apply to the provision or clause immediately preceding. Where the by-laws of a society provided first for an annual meeting for the election of officers, and then for a monthly meeting on a specified day "at half past seven o'clock p. m." It was held that the clause specifying to the hour of the meeting had reference only to the monthly meeting. (Lewis Southerland, Statutory Construction, 2nd ed., Sec. 420.)

But the same work and same section states:

> qualifying words have been applied to several preceding sections where the nature of the provisions and the obvious sense required it. * * *

Therefore, it would seem unimportant what the negative mandate modifies, as chiropractic does not include other than hand adjustment of the vertebra of the back and practically all mechanical, hygienic and sanitary measures are within the realm of the five prohibited fields embraced in or carved out of the field of medicine.

INTERPRETATION OF THE PHRASE "SHALL AUTHORIZE THE HOLDER TO PRACTICE CHIROPRACTIC IN THE STATE OF CALIFORNIA AS TAUGHT IN CHIROPRACTICE SCHOOLS OR COLLEGES"

According to Article IV, Section 1, of the Constitution the Legislature is vested with all legislative power, except in so far as the people reserve to themselves the power to propose laws and amendments to the Constitution and to adopt or reject the same, at the polls, independent of the Legislature.

In *Wallace* vs. *Zinman*, 200 Cal. 585, it was contended that an initiative measure was a constitutional amendment and that as a constitutional amendment it need not conform to the provision of the Constitution requiring every subject contained in the Act to be expressed in its title. It was held that an initiative measure had no greater strength or dignity than a legislative act and had to conform to the Constitution.

If this be the rule as to the initiative measures conforming to that portion of the Constitution requiring the subject of an act to be expressed in its title, it follows that it is likewise the rule in so far as the constitutional requirement prohibiting a delegation of legislative power is concerned.

In the case entitled *In re Peppers*, 189 Cal. 682, it was held that the Legislature had no power to delegate to an administrative board or officer its exclusive power and function of determining what acts or omissions on the part of an individual are unlawful.

In *Knight* vs. *City of Eureka*, 123 Cal. 192, it was held that the Board of Supervisors might not delegate to an attorney power to employ another "if, in his judgment, it becomes necessary."

In *Ex Parte Cox*, 63 Cal. 21, an Act authorizing a commission to make certain quarantine regulations and declare that a violation of them should constitute a misdemeanor was held to be unlawful as a delegation of legislative power.

In *Ex Parte McNulty*, 77 Cal. 164, it was held that the Legislature could not delegate to a board of medical examiners the power of declaring what acts should constitute a misdemeanor.

Petitioner contends throughout his opening brief that a chiropractor can practice any branch of the healing arts which any chiropractic school teaches as "chiropractic." Obviously his contention is based upon the theory that the Initiative Act permits a chiropractic school or college to determine what is chiropractic.

It is evident that if the petitioner is correct in his contention, the Chiropractic Act amended Article III, Section 1, of the State Constitution, and there are now four separate departments of the State government, namely, the executive, judicial, legislative, and chiropractic schools and colleges. Being somewhat old-fashioned, we still contend Article III, Section 1, means what it says, to wit:

> The powers of the government of the State of California shall be divided into three separate departments—the legislative, executive, and judicial; * * *.

Under the cases above cited and under the constitutional section, petitioner's contention must fail, as no law has ever been sustained which permitted the faculty of a school to determine what acts might be performed by a person holding a qualified type of licensure. Surely, it cannot be seriously contended that if a chiropractic school taught its pupils that surgery was chiropractic that a chiropractor might thereafter practice surgery.

Petitioner's contention falls squarely in the category of the case of *Ex parte McNulty, supra*, and if a school can determine what is chiropractic, a person can be punished under Section 15 of the Act for doing an act determined to be chiropractic by the school and not by the proper legislative power.

Of a consequence we conclude that the language "in the State of California as taught in chiropractic schools or colleges" means nothing, for, in the first place, the State of California could not grant a license to practice chiropractic in another state (*Dent* vs. *West Virginia*, 129 U. S. 114), and in the second place, if chiropractic schools could determine what constitutes chiropractic, Article IV, Section 1, of the Constitution would be violated .

THE HISTORY OF CHIROPRACTIC IN THE STATE OF CALIFORNIA AND THE EFFECT THEREOF ON THE INTERPRETATION OF THE CHIROPRACTIC ACT

Before the chiropractic law was adopted in California chiropractors had to have a license either as a physician and surgeon or as a drugless practitioner. (*People* vs. *Chung*, 28 Cal. App. 121; *Ex parte Greenall*, 153 Cal. 767; *People* vs. *La Barre, et al.*, 193 Cal. 388.)

In 1920, a chiropractic initiative measure was on the ballot and was defeated. It provided, among other things (Section 6, subdivision c), that a chiropractor would be authorized to practice obstetrics (Section 11); that they might sign birth certificates and diagnose and use such natural agencies as water, food, heat, and electricity, manual and mechanical means and manipulations as auxiliaries in their practice.

The argument in favor of the Chiropractic Act specifically stated:

> It does not permit chiropractors to practice medicine or surgery.
>
> Chiropractic is not taught in medical schools nor medical textbooks. The medical doctors neither understand nor believe in chiropractic. They are not competent to examine chiropractors.

It is settled that to ascertain the spirit, intention and purpose of a law a court may look into contemporaneous and prior legislation on the same subject and the external and historical facts and conditions which lead to its enactment. (*Grannis* vs. *Superior Court*, 146 Cal. 245.)

In case of uncertainty as to the construction of an initiative act, it is proper to resort in aid of its interpretation to the arguments submitted to the voters at the time it was voted upon. (*Crooks* vs. *People's Finance and Thrift Co.*, 111 Cal. App. Supp. 769.)

Applying these canons of statutory interpretation, it is quite evident that in the year 1920 an attempt was made to have chiropractic include healing measures which are absent from the Act of 1922 as adopted. There is nothing in the Act of 1922 which permits a chiropractor to do obstetrics or to use water, food, heat, and electricity in his practice.

In the year 1922 a chiropractic measure eliminating medical practices was proposed to the people. The argument in favor of the proposed act stated: It

> prohibits the use of drugs, surgery or the practice of obstetrics by chiropractors * * * the teachings and practice of chiropractic are admittedly different from those of medicine.

It would hence appear that chiropractic has a definite meaning and does not include the many matters contended for by the petitioner, McGranaghan.

AS TO MECHANICAL, HYGIENIC AND SANITARY MEASURES

The evidence in the matter at bar shows that there are necessary chiropractic mechanical, chiropractic hygienic and chiropractic sanitary measures. The testimony shows that at one stage in chiropractic a rubber hammer was used upon the vertebra of the spine. While not generally accepted by the profession, it is unquestionably a mechanical measure and as such was used in the year 1922. There is testimony that the chiropractic table is a necessary mechanical measure.

The only evidence in the record as to what is a chiropractic hygienic measure relates to the use of paper towels. These, it appears, are placed upon a chiropractic table and the patient's face placed thereon. The purpose of this is to prevent the patient from coming in contact with such perspiration or disease germs as may have been left by a preceding patient.

There are few sanitary measures which are strictly chiropractic. Indeed, most things used in sanitary measures are included in the realm of *materia medica*. The use of soap and water for cleansing the body of a patient is distinctly a sanitary measure and is not prohibited by Section 7.

As early as the year 1926, it was conceded by the Attorney-General that a chiropractor might use an x-ray for the purpose of analyzing or diagnosing the physical condition of a patient. Our opinion rendered at that time reads as follows:

> January 26, 1926.
>
> State Board of Chiropractic Examiners,
> Forum Building,
> Sacramento, Calif.
> Attention: Dr. James Compton, Secy.
>
> Gentlemen:
>
> I have before me your communication under date of January 2nd, 1926, which is as follows:
>
> "Section seven of the Chiropractic Act states, in substance, that a licentiate of the State Board of Chiropractic Examiners is authorized to practice Chiropractic in the State of California, as taught in chiropractic schools or colleges, and also, use all necessary mechanical and hygienic and sanitary measures incident to the care of the body.
>
> "In order that this Board may have a definite understanding of what is meant by the use of 'all necessary mechanical and hygienic and sanitary measures,' in connection with the practice of chiropractic, we would appreciate an official opinion from you relative to the meaning of that portion of section seven to which we have referred.
>
> "We particularly desire to know if a licentiate of this Board may legally use, or hold himself out as using, electrotherapy, hydrotherapy, electronic medicine, etc., as therapeutical agencies in the treatment of disease; or, may he use mechanical agencies only for the purpose of analyzing or diagnosing disease, such as x-ray, stethoscope, neurocalometer, etc."
>
> It would appear that the language of the act authorizing the use of chiropractors of "all necessary mechanical and hygienic and sanitary measures" incident to the care of the body in itself answers the question which you submit, for clearly, sciences, systems or methods for the treatment of disease, such as electrotherapy, hydrotherapy and other systems of treatment, do not come within the scope of chiropractic practice.
>
> It is undoubtedly true that a duly qualified and licensed practitioner of chiropractic may make use of an x-ray machine for the purpose of analyzing or diagnosing the physical condition of a patient but would not be authorized under the act to make use of that machine for the treatment of disease or illness, for that would constitute the practice of medicine which is not included within the science of chiropractic.
>
> The words of the statute in section 7, permitting the use of all necessary mechanical and hygienic and sanitary measures incident in the care of the body, must be construed in a sense restricted to chiropractic. In construing statutes wherein we have words of general sense in conjunction with words of a specific sense, the words of the greater general meaning are restricted by the words of more specific meaning. Take, for instance, the x-ray above referred to. The use of the x-ray therapeutically is the practice of medicine. The use of the x-ray in the chiropractic sense would restrict its use to purposes of analysis or diagnosis, to locate the position of the vertebrae and the relation of one vertebra to another.
>
> This would seem to illustrate the difference between the use of the x-ray as a medical agent and its use as a chiropractic agent.
>
> As to sanitary measures, there would no doubt be a greater range in the use of sanitation as contemplated in the practice of chiropractic than there would be in the use of mechanical measures. Sanitation is inherent in all the healing arts, but the sanitary measures to be used by chiropractors must be confined to those things which are strictly sanitary as distinguished from therapeutic measures used in medicine. Therefore, generally speaking all mechanical, hygienic and sanitary measures used by chiropractic licensees must be construed strictly with the chiropractic idea in mind.
>
> I am therefore of the opinion, to directly answer your query, that a chiropractic practitioner is not, as such, authorized to employ electrotherapy, hydrotherapy, electronic medicine, etc., as therapeutic agencies in the treatment of disease but may with propriety use mechanical agencies such as the x-ray, stethoscope, neurocalometer, etc., purely for the purpose of analyzing or diagnosing for chiropractic treatment.
>
> Very truly yours,
> U. S. Webb, Attorney General,
> By Leon French, Deputy.

CONCLUSION

We have set forth herein what matters constitute chiropractic and ask that this honorable court declare that the petitioner has the right to practice those things only which are within the philosophy of chiropractic and that the use of all therapeutic and electrical appliances, as well as the prescribing of diets, are prohibited by the terms of Section 7 of the Chiropractic Act.

U. S. Webb,
Attorney-General of the State of California.
Leon French,
Deputy Attorney-General of the State of California.
Lionel Browne,
Deputy Attorney-General of the State of California.
Attorneys for Intervenor, The People of the State of California.

COURT DECISION ON CHIROPRACTIC CASE

IN THE SUPERIOR COURT OF THE STATE OF CALIFORNIA, IN AND FOR THE COUNTY OF SAN FRANCISCO*

Honorable John J. Van Nostrand presiding.

No. 257362

In the Matter of the Application of M. James McGranaghan, for Declaratory Relief, Plaintiff, vs. Dora Berger, Intervenor and Defendant, vs. Roy B. Labachotte, Intervenor and Defendant, vs. The People of the State of California, Intervenor.

MEMORANDUM OF OPINION

This is an action in declaratory relief instituted by M. James McGranaghan seeking an interpretation of Section 7 of the Chiropractic Act. Roy B. Labachotte, Dora Berger and the People of the State of California have filed separately complaints in intervention also asking for an interpretation of the same section, which reads as follows:

> One form of certificate shall be issued by the board of chiropractic examiners, which said certificate shall be designed "License to practice chiropractic," which license shall authorize the holder thereof to practice chiropractic

---

* This is the opinion handed down by Judge John J. Van Nostrand. For Brief on this case, see page 414. Editorial comment is made on page 380.

in the State of California as taught in chiropractic schools or colleges; and, also, to use all necessary mechanical, and hygienic and sanitary measures incident to the care of the body, but shall not authorize the practice of medicine, surgery, osteopathy, dentistry or optometry, nor the use of any drug or medicine now or hereafter included in materia medica.

Much testimony has been introduced and the matter ably and fully argued and briefed by respective counsel.

The District Court of Appeal, in the case of *Evans* vs. *McGranaghan*, said in part:

> It contains no definition of "Chiropractic as taught in chiropractic schools or colleges. . . ."

Also,

> The intent of the statute is clear upon its face: that the license shall authorize the holder to practice chiropractic as taught in chiropractic schools or colleges. But the court has no way of determining the scope of chiropractic as taught in such schools and colleges in the absence of evidence on that subject, and hence a resort to such evidence would be proper.

After a careful analysis of the testimony, the arguments and authorities cited, I am of the opinion that "chiropractic as taught in chiropractic schools or colleges" means the practice of chiropractic as such, irrespective of the subjects embraced in the curriculum, such as minor surgery, obstetrics, replacing shoulder, hip, rib and foot subluxations and dislocations, etc., which I am of the opinion are embraced in the field of medicine or surgery, and not a part of chiropractic. As counsel for one of the intervenors aptly states: "It may be that a student in dentistry would embrace in his curriculum the study of anatomy, but this would not justify him in practicing either surgery or medicine."

I am further of the opinion that under Section 7 of the Act a chiropractor would have no right to do any of the enumerated things in Sections 8 and 17 of the Medical Practice Act, nor the right to treat the eye, ear, nose, and throat; although I am not of the opinion that a manipulation of the vertebrae of the spine would be included in the word "surgery" as contemplated in the Medical Act, nor can I see under the provisions of this Act where a chiropractor has the legal right as such to practice osteopathy as defined in the cases of *Harlan* vs. *Alderson*, 55 Cal. App. 263, and *In re Rust*, 181 Cal. 73. I am, likewise, of the opinion that under Section 11 of the Dental Laws of the State of California, a chiropractor has no legal right to perform an operation on the teeth of a patient, or "treat diseases or lesions of the human teeth, alveolar process, gums or jaws or correct malimposed positions thereof, or construct, alter, repair or sell any bridge, crown, denture or other prosthetic appliance or orthodontic appliance."

Chapter 598 of the Statutes of 1913 definitely defines "optometry," and I cannot see how it in any manner or form can be included in the term "chiropractic" either in the treatment of the eye or in the use of either lenses, or frames, permanently or temporarily.

I am not in accord with the position assumed by the plaintiff herein as to the unconstitutionality of the words "materia medica," for they have a well-defined and recognized meaning, and have been frequently used by the courts of this state, and consequently I hold that the chiropractor has no right to administer or prescribe drugs or medicines.

I am further of the opinion that the words "all necessary mechanical, and hygienic and sanitary measures" would include the use of the x-ray for the purpose of analysis or diagnosis of the physical condition of the patient, but not for the purpose of treating disease or illness. The same is true as to the stethoscope, neurocalometer, and kindred modalities which might properly be used for diagnostic purposes.

Such appliances or agencies as the chiropractic table, chiropractic hammer, and towels and other instrumentalities as are purely sanitary do not violate the statute, but the use of the various therapeutic agencies such as electrotherapy, hydrotherapy, colonic therapy, etc., are embraced in the practice of medicine and, therefore, forbidden to chiropractors.

John J. Van Nostrand,
Judge of the Superior Court.

Dated September 28, 1936.

THE LURE OF MEDICAL HISTORY†

THE HUNTERS IN EMBRYOLOGY*

By A. W. Meyer, M.D.
Stanford University

I**

The famous Scotchmen, John and William Hunter, have always occupied a prominent place in the history of medicine, and deservedly so. William also has usually been given a place in the history of embryology almost wholly denied John. Yet Duncan,[1] who championed William in his well-known volume, declared in the Harveian address of 1876 that William "left behind him scarcely anything to perpetuate his memory, except the work on the Gravid Uterus, which, though undoubtedly of great merit, has had no very extensive influence on the progress of knowledge, and cannot in any way be compared with what has been effected by his brother." (p. 1077.)‡ However, Rádl,[2] in his *Geschichte der biologischen Theorien,* barely mentioned John, merely listing him among some other comparative anatomists, and Bilikiewicz[3] only mentioned John in a footnote, although he used the name of his brother for a subtitle. Nordenskiöld,[4] however, gave John, instead of William, a place in his History of Biology. He pointed especially to John's treatise on teeth and to his ideas regarding the blood and his comparative anatomical work. Needham,[5] on the other hand, mentioned both William and John in his History of Embryology, referring to the former as an embryologic iconographer, and especially emphasized John's connection with the idea of recapitulation.

It is not surprising that the unexcelled and sumptuous "elephant" folio on the gravid uterus,[6] for the "elaborateness" of which the author felt it necessary to apologize, attracted great attention at the time of its appearance in 1774, and that it has been extolled very often since that day. It will be recalled that this atlas on human pregnancy is composed of thirty-four excellent, large plates, 47 by 64 centimeters, the work of accomplished artists, and of engravers supervised by Robert Strange, who himself executed two of the plates, causing Hunter to say that Strange had thereby "secured a sort of immortality" for the plates. This atlas is characterized quite adequately by Choulant,[7] and also was commented upon with great appreciation by von Siebold[8] in his *Geschichte der Geburtshülfe.*

WILLIAM HUNTER'S DISSECTIONS

William, who was famed as an obstetrician, apparently had dissected mammals late in gestation in order to enlarge his knowledge of the subject, and said that he projected the above volume when he

> met with the first favourable opportunity in 1751 of examining, in the human species, what before he had been studying in brutes. A woman died suddenly, when very near the end of pregnancy, the body was procured before any sensible putrefaction had begun, the season of the year was favourable to dissection.

With "the assistance of many friends," he was able to secure twelve more bodies in a similar state, in the preparation of which, for the artists, John played an important part. William expressed his indebtedness to John in the last paragraph of the preface to his treatise on the gravid uterus, for his skill in dissection. The latter's share in the production of it hence received public recognition from the time of the appearance of this treatise, twenty-six years after he joined William, even if not from the very beginning of the undertaking.

In the Gravid Uterus, William said that he expected to publish an additional plate representing "a younger human embryo than he had seen heretofore, and also a tubal pregnancy which he had drawn," and he added that if he "should be prevented from doing this by any unforeseen accident," it would be "in the power of many gentlemen of the profession to do it" for him, because he had "constantly explained his observations on this subject in his public lectures." He apparently never found the leisure for doing these things and his professional friends apparently failed him, for according to Teacher[9] (1900), "He never carried out this scheme, and there is no detailed description of either of these cases, nor sketches of the embryo in the museum. The embryo and placenta from the extra-uterine case are the original of the illustration in Quain's *Anatomy* 'after Allen Thomson,' tenth edition, vol. i, pt. i, p. 104, fig. 124. Professor Thomson sketched it for the seventh edition, 1867, in which it appeared as Fig. 603." (pp. lix-lx.) According to this, then, the drawing did not appear in the posthumous volume on the uterus which appeared in 1794.

THE NAME, DECIDUA

According to Teacher (p. lii), William invented the name decidua for the spongy chorion, and believed (p. liv) in 1775 that the placenta " 'is partly made up of an excrescence from the uterus itself . . . the internal membrane of the uterus, which I have named decidua, constitutes the exterior part of the secundines, or after-birth . . .' " Moreover, from the text accompanying Plate 34 of the Gravid Uterus, which appeared in 1774, it is evident that William regarded the decidua itself as a conception, which also indicates that he regarded it as a growth. He had a correct idea of the gross relations of the chorionic vesicle to the decidua, and the decidua externa (vera) and reflexa long were known as the Hunterian membranes. However, as far as I have been able to learn, he did not use the term serotina, as von Siebold[8] (1902) said, but spoke of a lamella externa instead. Webster[10] (1901) said that John named the decidua serotina and plainly implied that it also was he who named the reflexa, while Williams[11] (1903), on the other hand, wrote: "The terms reflexa and serotina date from the time of William Hunter, who gave excellent drawings of the decidual membrane in his atlas. Unfortunately, the author died just after its appearance and before the completion of the explanatory text, which was prepared by John Hunter and Matthew Baillie . . ." (p. 106), and he attributed John's idea of the formation of the decidua to William. This statement was partly corrected in a later edition[12] (1931), but not without the introduction of other errors, as the following quotation shows:

> The terms *reflexa* and *serotina* date from the time of William Hunter, who gave excellent drawings of the decidual membrane in his atlas. Unfortunately, the explanatory text was prepared by John Hunter and Matthew Baillie, who considered that the decidua represented a fibrinous exudate from the lining membrane of the uterus, which not only formed a complete cast of its cavity, but also covered the tubal openings. They supposed, therefore, that when the ovum reached the uterine end of the tube its further passage was opposed by the decidua vera, which it was obliged to push before it as it entered the uterus, whence the term *reflexa*; consequently, after the latter had been pushed forward, a new exudate was developed behind the ovum, to which the term *serotina* (late) was applied (Figs. 140 and 141). (pp. 137-138.)

The figures referred to are "Diagrams Illustrating Hunterian Theory of Formation of Decidua Reflexa," after the manner of Carpenter[13] (1845), page 601.

It is perplexing that an anonymous auditor[14] of William Hunter's lectures stated (p. 85) that William said he first called the decidua "Caduca,"

Also the treatment of women in time of labour, etc. (undated MS. notes occupying pp. 71-181 of volume with cover title, "Ray on Teeth. Hunter. Gravid Uterus.").

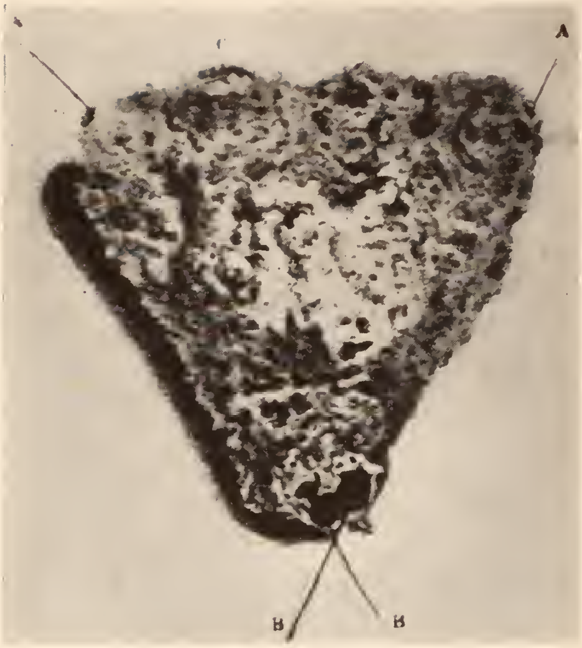

Fig. 1.—Figure 5 of Plate 34, after the Atlas of 1774.

but changed it to decidua when he found that it was temporary. According to this auditor (p. 99), William also declared in his lectures that

> The decidua in the early months lines the uterus loosely with it, [.] at [At] the edges of the placenta. [,] It [it] divides into 2 strata, one of these runs under the placenta, between it & the uterus, & the other is reflected over the membranes. The last is called the decidua reflexa.

It should be noted that this statement is in complete accord with that written by William and contained in the explanatory text accompanying the tables of the Gravid Uterus. A good statement regarding this matter is found in Fasbender,[15] who, however, attributed John's idea of the formation of the decidua to William, perhaps because as Duncan[16] (1868) said:

> In 1780, . . . John Hunter inaugurated the errors in regard to the decidua which have been finally overthrown only in our own time and which still maintain a lingering existence in obstetric literature. (p. 230.)

Fasbender called attention to the fact that Vesalius and Fabricius had represented the decidua, and that this was done also by Noortwyk, who thought that it formed part of the chorion (substantia fungiosa chorii), an opinion held even by Baudelocque (1746-1810), according to Meckel (I, p. 306, quoted by and from Fasbender). Meckel said that Baudelocque rejected the idea of certain anatomists who regarded the decidua as a separate membrane.

In the legend to Figure 5, Plate 34, which is a good representation of a decidual cast, William spoke of AA as representing

> A bristle passed through the cavity of the conception, through a hole at each of the upper angles, which was supposed to be the termination of the fallopian tube. BB. The same bristles coming out through a large hole at the lower angle, supposed to be opposite to the cervix uteri. C. A small hydatide, supposed projecting through the surface of the decidua, which had slender branching filaments shooting from the surface, supposed to be the chorion."

As indicated by the drawing, the hydatid mentioned by William no doubt was a chorionic vesicle, as he thought, and apparently was devoid of an embryo and probably also of an amnion and a yolk sac. The "slender branching filaments shooting from the surface" manifestly were "magma reticule," often so abundant in conceptuses retained after their death.

CLINICAL NOTES AND CASE REPORTS

A MEDIASTINAL TUMOR*

By Jessie M. Bierman, M.D.
San Francisco

HISTORY.—Case 36165: A boy of eight and one-half years had always been delicate. He suffered from eczema during infancy, and following bronchopneumonia at three years he was subject to attacks of asthma. He was sensitive to egg-white and fish. He had many colds, and at the age of five and one-half years again had bronchopneumonia. He was fairly well the following year until November, when his appetite failed; he lost weight and looked pale. He continued at school until December 12, when he was discovered to be running a slight fever and had become very irritable.

He entered the Children's Hospital, January 8, 1935.

Physical Examination.—He was small, poorly nourished and very pale, but did not look acutely sick. The eyes, ears, and nose appeared normal. A few shotty glands could be felt in the anterior triangles of the neck, the axillae, and the inguinal regions. The teeth contained a number of filled cavities. The gums were healthy. The tonsils were small and not injected. The left shoulder was held higher than the right. The veins of the left upper thorax were distended. Movement of the left chest was diminished. Tactile fremitus was absent over the upper part of the chest, anteriorly and posteriorly. There was dullness over the left upper chest anteriorly, from the supraclavicular space downward merging into cardiac dullness. The dullness extended laterally to the midaxillary line in the third interspace, from which it reflected anteriorly to the midclavicular line, leaving a small area of hyperresonance lateral to the cardiac apex in the fourth and fifth interspaces. To the right of the sternum the dullness extended 2½ to 3½ centimeters in the second and fourth interspaces, respectively. Posteriorly, the dullness occupied an area corresponding to that noted anteriorly, with an area of normal resonance in the axillary line. The breath sounds were tubular over the apex of the left lung. Strident, whistling breath sounds were heard below the clavicle.

The cardiac P. M. I. was in the midclavicular line in the fifth interspace. The cardiac borders were obscured by the dullness above described. The heart sounds were distant. A faint systolic murmur was heard at the base. The blood pressure was 102/60.

The abdominal wall was thin and relaxed. The liver dullness extended from the fifth interspace to 2½ centimeters below the costal margin in the nipple line, and was not tender. The spleen extended 5 centimeters below the costal margin. It was elongated, firm, and slightly tender.

The temperature was 99 degrees Fahrenheit; pulse, 88; respiration, 24. The urine showed nothing abnormal.

Blood: Hemoglobin, 54 per cent; red blood cells, 3.8 M; white blood cells, 32,700.

The differential count, done by Dr. H. G. Henderson on a fresh smear stained by the supravital method, showed: Polymorphonuclears, 5; lymphocytes, 90; myelocytes, 2; monocytes, 2; basophils, 1.

Most of the lymphocytes were immature and young forms. There was some variation in the size and shape of the red cells, and an occasional nucleated form.

Platelets, 190,000; coagulation time, five minutes; bleeding time, four minutes; tuberculin, negative; Wassermann, negative.

Diagnosis.—The elevated shoulder, diminished respiratory excursion, absent tactile fremitus and thoracic dullness suggest pleural effusion, but doubt as to the correctness of this diagnosis is indicated by the normal position of the cardiac apex and by the unusual distribution of the dullness even for an encapsulated or interlobar collection of fluid. The peculiar whistling breath sounds suggest compression of a bronchus. The dilated veins over the left chest indicate pressure against the superior vena cava or its branches. A mediastinal tumor would best explain all these findings. This diagnosis was confirmed by the x-ray, in which a large tumor mass was seen to occupy the anterior mediastinum mainly on the left, obscuring the lung field except for a narrow lateral portion.

Of the mediastinal tumors likely to be encountered in childhood, lymphocytoma, lymphosarcoma, dermoid cyst or teratoma, there is strong evidence in favor of lymphocytoma or leukemic infiltration in the enlargement of the spleen and the blood picture. The blood picture shows a large number of immature lymphocytes, which makes the diagnosis of acute lymphatic leukemia likely. That the disease is in the early stage is indicated by the lack of evidence of infiltration of other organs or lymph glands, the normal coagulation and bleeding time, and the relatively good general condition of the patient.

Progress and Treatment.—The temperature ranged between 98 and 101 degrees Fahrenheit for three weeks to January 31, after which it swung to 104 degrees Fahrenheit.

X-ray treatment to the chest was begun January 12 and repeated at five-day intervals. The doses were small (48 to 65 R.). On the day of the second treatment, the tumor mass was slightly smaller to percussion, and according to tracings made with the aid of the fluoroscope. After the fourth treatment the mass was definitely smaller. The blood picture was much the same, except that the lymphocytes had increased to 99 per cent, with many immature forms.

By January 30 the liver and spleen both extended to the level of the umbilicus. The cervical glands were considerably enlarged. The patient was drowsy and he had a profuse nosebleed. The white count was 57,400, the hemoglobin 50 per cent. From this time on there was a succession of severe hemorrhages from the nose, into the right auditory canal and temporal region.

On February 9, petechial hemorrhages appeared over the entire body; the white count was 73,000 with 98 per cent lymphocytes. Two days later it dropped to 3,700, with 100 per cent lymphocytes; and on the day of death, February 14, the white count was 300, hemoglobin 17 per cent.

Every type of supportive treatment, including transfusions, hematinics and hemostatics, were used without affecting in any way the rapid progress of the disease. There is no doubt that the x-ray therapy did decrease the size of the mediastinal tumor, but certainly did not delay the outcome of this invariably fatal disease.

384 Post Street.

PEPTIC ULCER*

By John W. Shuman, M.D.
Los Angeles

HERE is an old, old story; only it happened this year! And it involves a number of the staff of this hospital and a patient who was a "stomach complainer."

The latter was a 46-year-old salesman, who had had more than his share of family and financial troubles prior to a consultation in March, 1935. In late 1934 he had suffered an acute pain in the upper belly, which necessitated opiates and bed rest for several weeks—quite likely an "acute abdomen." Later, an ex-ray study of the stomach found for "ulcer of the stomach." The medical consultant's findings in March were: "A dyspeptic individual who was afraid of dentist, doctors, and life itself; the usual history of 'alcoholism'; a marked tremor; pulse fast; insomnia; periods of

---

* From the Department of Pediatrics, Children's Hospital, San Francisco.

* Presented on December 5, 1935, at the Hollywood Hospital Weekly Pathological Conference.

'sour stomach'; vomiting and pain, following eating." The man had heard the erroneous and pernicious teaching that "all stomach cancers begin in ulcer," and was "sold" on the idea that his stomach needed an operation. This notion has added false fears to many others suffered not only by patients, but also by surgeons and internists.

STOMACH ULCERS

Before proceeding with this man, let us reason that most ulcers occur near the outlet of the stomach because of pyloric muscle spasm. The reaction of the sympathetic nerves due to overstimulation by thyroxin, which got its whip-up from disturbing ideations, focal infection or the like, causes pylorospasm. This shuts off the blood supply to the mucosa, and good old hyperchlorhydria does the denuding, leaving an open sore. Spasms of the glottis, esophagus, ileocecal junction, colon and rectum are no rarities. If the ulcer is small and the spasms discontinue, healing is the result. Any pathologist can show us many healed ulcers discovered at autopsy which were not suspected during life. The ulcer that heals spontaneously is uninteresting. The one which gnaws through the wall of the stomach or duodenum, the bleeder and the incurable ulcer, are the ones which toss us for loops. Since the advent of the x-ray, aided by the opaque meal, more ulcers of the stomach are diagnosed . . . some which cannot be found even at operation or autopsy!

With reference to diagnosis, and periodicity of attacks:

1. "Hunger pains" (coming two to three hours after eating).

2. "Food ease" (often "soda ease," lasting for two or three hours).

3. "Hypersecretion" (the spitting or vomiting of sour material).

4. "Hyperacidity" (sour stomach, often called "heart burn." . . . These make a quartet that sing, "Suspect a peptic ulcer!" We should then check stools for blood; and if a gastro-intestinal x-ray series can be afforded, it should be made. The fluoroscope should be generously used in viewing the stomach during its filling and emptying, for ulcer defects.

The duodenal-ulcer patient is usually well nourished, because food is taken often and copiously enough to secure the "food ease." The stomach-ulcer patient is the dyspeptic, thin type—afraid to eat because of food distress, especially if the ulcer has perforated and is adherent to a neighboring viscus. The ulcer which bleeds will show, on a meat-free diet, occult blood in the stool with benzidin. Let us remember, however, the therapeutic test for our poorer patients, namely, the feeding of a bland nourishing diet, *e. g.*, milk and cream every three hours (even at 1 a. m. by the alarm clock) with regular meals. If the pain disappears, diagnose "ulcer" and continue the patient on the anti-ulcer diet. This diet needs no man's name. This may be supplemented with "Arm & Hammer" brand soda, since it costs less. Sure, bismuth subnitrate and belladonna may be added for mystery's sake: anything for comfort, but keep the patient comfortable, mentally as well as physically. Three weeks in bed with a continuous dripping of milk through a small tube into the stomach made a physician's chronic ulcer comfortable last month. He had gotten fatigued carrying his milk bottle under one arm and alkaline powders under the other!

PATIENT'S STORY

To return to our patient's story: the consultant agreed with the diagnosis of "peptice ulcer." Where it was located he did not know, nor was he certain of its character. He advised:

First: A more careful medical regimen, and no operation for some time.

Second: Lugol's solution, drops five to ten, three times a day, because of moderate hyperthyroidism. The patient tolerated ten drops three times a day, which proves, at any rate, that he was not a hypothyroid.

Third: A clearance of the dental and peridental focal infection, which was severe. This was not done. The man had a gastro-enterostomy in this hospital in August. An ulcer was found, which was plastered against the pancreas; no attempt, of course, was made to loosen good old nature's patch, which she put there last year when the perforation occurred.

SURGICAL INDICATIONS

Here are the indications for surgical management of peptic ulcer:

1. Perforation. Immediate operation to help nature close the hole.

2. Obstruction at the pylorus (not by spasm). A gastro-enterostomy is a blessing.

3. Pain. The ulcer which does not yield to proper medical management begs for surgery.

4. Hemorrhages. Repeated.

Pain and hemorrhages are often debated. Let us not debate them, or we lose cast with one another. This patient recovered from his operation and is getting confidence in his gastro-enterostomy; but—

POSTLUDE

Last Sunday morning at one o'clock the patient telephoned: "I have $25 for the doctor who will relieve the neuralgia in my left face. I've taken all the pain killers in the house!" The next day the upper left wisdom tooth was found to be the cause. It was extracted and the neuralgia cured! He stated that he recently had had neuralgia in his low-back and neck. Here are the films of the teeth. They were made in this hospital and interpreted "no pathology." That wisdom tooth is not on there because the patient gagged when the films were made! Then take a closer look and one sees that the right lower second molar is dead and abscessed. Here it is as well as two others, which were practically lifted with the fingers.

Thank God for local pain! The man is having his mouth put in a healthy condition—truly a little late, but better than never.

3780 Wilshire Boulevard.

BEDSIDE MEDICINE FOR BEDSIDE DOCTORS

An Open Forum for brief discussions of the workaday problems of the bedside doctor. Suggestions of subjects for discussions invited.

HYPERINSULINISM-HYPOGLYCEMIA

I. ETIOLOGY

H. CLARE SHEPARDSON, M.D. (384 Post Street, San Francisco).—The proper classification of diseases of the ductless glands has depended upon the recognition of states of over- and underfunction. Occasionally the characteristic syndrome resulting from a disturbed activity of one of the members of the hormonopoietic system has been described prior to its experimental reproduction. For example, gigantism was long suspected as being due to an exaggerated activity of the anterior hypophysis before Evans produced it in rats by injections of an extract of that gland containing the growth-stimulating hormone. In many instances, however, the clinical recognition of such a syndrome has been delayed until such time as the experimental investigator has obtained an active extract. Thus, the etiology of osteitis fibrosa cystica (von Recklinghausen's disease) was not suspected until Collip had secured an active extract of the parathyroid glands. And, although the relationship of diabetes mellitus to pathologic alterations in the islands of Langerhans was postulated by Opie many years before the insulary hormone was isolated, its exact status as a hypofunctional state of the internally secreting portion of the pancreas depended on the relief of diabetes by supplementary therapy with insulin. And it was inevitable that the opportunity to test this hormone clinically and experimentally would ultimately shed light on the effects of overdosage and lead to the recognition of the clinical state of hyperinsulinism.

The similarity in the symptomatology resulting from the hypoglycemia caused by insulin overdosage to the syndrome presented by certain individuals led Harris, in 1923, to investigate the glucose content of the blood stream at various hours during the day in a group of asthenic patients. Two cases with abnormally low blood sugar were described, and an overactivity in function of the pancreatic islets was advanced in explanation. Harris reasoned that it is possible, in view of the fact that the islet tissue of the pancreas is an hormonopoietic organ, not only to have an insufficient secretion (resulting in diabetes mellitus), but an excessive or altered secretion which would produce the symptoms described.

Yet spontaneous hyperinsulinism is to be distinguished from spontaneous hypoglycemia. The latter is merely a descriptive term indicating the lowering of the blood sugar, a condition which may be induced by a variety of causes. Glucose is one of the principal sources of cellular nutrition, and elaborate hormonic and nervous regulation is provided to maintain a fairly stable concentration of this substance in the blood. Not only are several of the glands of secretion engaged in this regulation, but, in addition, a nervous control is maintained, either directly through the liver, or indirectly by way of the pancreas and suprarenal glands.[1]

The various causes of spontaneous hypoglycemia have been summarized by Barnes and Richmond,[2] as follows:

1. Excess of insulin as a result of therapeutic injections of commercial insulin, of tumors and hyperplasia of the pancreas or of functional hyperinsulinism.

2. Lack of opposing secretions resulting from diseases of the suprarenal glands, the hypophysis and possibly of the thyroid gland.

3. Lack of glycogen. This deficiency may result from destruction of the glycogen reservoirs produced by disease of the liver or by wasting of 3
the muscles, or by starvation.

4. Interference with the regulating center, caused by disease affecting the pons, or from overactivity 2
of the vagus nerves.

The chief source of the blood sugar is the store of glycogen in the liver, although when food is being absorbed from the intestine it can be assumed that the sugar content of the blood is augmented from that source directly. Consequently, the actual destruction of a large amount of hepatic tissue will so hinder the formation of glycogen that a glycopenia will ensue. As early as 1874 Brock and Hoffman found that the sugar disappeared from the blood within an hour after ligation of the blood vessels going to and from the liver. Also Mann demonstrated a marked drop in the blood sugar of dogs five hours after hepatectomy. Rabinowitch, in 1929, referred to the marked hypoglycemia of a patient with almost complete suppression of hepatic function resulting from idiopathic acute yellow atrophy of the liver, and Parnos and Wagner reported the case of a girl with a tumor of the liver in whom no blood sugar was demonstrable. Nadler and Wolfer cited a patient in whom, although the usual signs of hepatic insufficiency were lacking, some 70 to 80 per cent of the substance of the liver was replaced by neoplastic tissue, and the remaining hepatic cells were deficient in glycogen; a condition which resulted in failure of the sugar mobilizing function of the liver with consequent hypoglycemia.[3]

Furthermore, an entirely different mechanism, which, however, gives an identical end-result, may be responsible for a loss of glycogen reserve and the consequent production of hypoglycemia. Various workers have demonstrated that the degree of hyperglycemia which develops following the injection of epinephrin is more or less proportional to the amount of glycogen in the liver (Ritzman, Pollock, Bang). A prolonged and continuous overactivity of the adrenals might so deplete the glycogen stores of the liver as to bring about a complete exhaustion of the chief source of the blood sugar. Anderson cites such an instance in which the patient died of hypoglycemic convulsions resulting from an excessive stimulation of gluconeogenesis in the liver by a carcinoma of the adrenals. On the contrary, it is conceivable that gluconeogenesis is maintained at a constant rate in the normal individual by the well-balanced activity of the adrenal glands. If such is the case, any diminution in this secretion would tend to inhibit the formation of glucose from glycogen in the liver. Thus, in Addison's disease hypoglycemia is almost a constant finding. Apparently, then, hypofunction, as well as prolonged hyperactivity of the adrenal glands, can bring about a continuous glycopenia which, if sufficiently severe, will result in the production of the definite group of symptoms clinically associated with marked reduction in the blood-sugar level.

[3] Shepardson, H. C.: Glycopenia—The Efficacy of High Fat Diets in the Treatment of Chronic Hypoglycemia, Endocrinology, 16:182-192, 1930.

Obviously, any interference, either organic or functional, with the production of glycogen, the storage of glycogen or gluconeogenesis occurring in the liver can result in the production of a hypoglycemia. It may be mentioned, also, apropos of hepatic insufficiency, that substances which have an injurious effect on the liver—for example, hydrazin, chloroform, phosphorus, arsenic—will cause hypoglycemia.

Alteration in function of at least one other member of the endocrine system not infrequently brings about a change in the usual level of the blood sugar. The work of Houssay, Evans, and others, seems to indicate that only in the presence of a properly functioning adenohypophysis can normal carbohydrate metabolism proceed; clinically, diabetes mellitus is not uncommonly associated with acromegaly, a disease resulting from an excessive activity of the acidophilic cells of the anterior portion of the pituitary gland. Contrariwise, patients classified as having a pituitary deficiency are occasionally seen in whom the glucose tolerance curve is extremely flat, indicating what, for the time being, must be considered a *relative* increase (in contrast to an actual excessive secretion) in the amount of circulating insulin.

Finally, hypoglycemia has been demonstrated in starvation, severe and strenuous exercise, progressive muscular atrophy, and in status thymicolymphaticus.

Probably, however, the vast majority of instances of spontaneous hypoglycemia result from an increased production of insulin, caused by either an organic or a functional overactivity of the islets of Langerhans. It must be admitted that the morbific factors in this excessive activity may be either neurogenic or the result of definite anatomic changes in the pancreas itself. And, from the few papers concerned with the intensive study of these cases, it likewise seems apparent that there is no striking difference between those cases with an adenoma or other pathologic alteration and those with no demonstrable pancreatic lesion.

However, like other ductless glands, tumors of the islet cells—adenoma and the like—might be expected to give rise to a syndrome, which, in some respects at least, should be the reverse of that produced by decreased activity, namely, diabetes mellitus. Hypoinsulinism and hyperinsulinism are, in fact, clinical antitheses; the latter is of as serious significance as the former, and the practitioner of today must be as familiar with the one as he is with the other.

Many reports of tumors of the islet cells producing the clinical picture of hyperinsulinism have appeared since Wilder and his associates published the first case in which was correlated clinical data, chemical studies, and pathologic examination. Space forbids any attempt to review the somewhat voluminous literature which has accumulated on this subject. Suffice it to say the symptoms are uniformly quite severe, although fortunately in many cases prompt diagnosis has resulted in surgical intervention with complete relief of the condition.

Although in some cases multiple adenomas have been present (for example, the cases of Frank, of Smith and Seibel, one studied by Wilder), in most instances the symptoms have been produced by a single small adenoma; and it is interesting that in the large majority of cases appearing in the literature the pancreatic lesion has been benign. Furthermore, in spite of the fact that the pathologist encounters hypertrophy of the islands of Langerhans with much greater frequency than tumors, symptomatology resulting from hypoglycemia has been associated with but relatively few cases of hypertrophy of the islet cells (Phillips, John, Mosenthal, Gray). However, of these cases of proved hypertrophy resulting in the clinical syndrome of glycopenia the case of Gray and Feemster is especially interesting and of great practical importance in considering the problems presented by the complication of diabetes with pregnancy. An infant born of an inadequately treated diabetic mother died on the fourth day with symptoms of hypoglycemia. It was proposed, following the finding of a marked hypertrophy of the island cells at necropsy, that this insular overgrowth occurred in response to the demand of maternal tissues for insulin, and that after delivery the supply of insulin in the child was excessive.

Finally, it is now well established that hyperinsulinism may exist without any demonstrable anatomic alteration of the pancreas; a phenomenon not surprising, since the opposite condition, diabetes mellitus, may likewise occur without visible change in the islands of Langerhans. In several reported cases clinically indistinguishable from those in which there are island tumors, no grossly nor histologically resognizable changes have been found in the pancreas.

In conclusion, then, it is apparent that hyperinsulinism results from disturbances in function of the hormonopoietic portion of the pancreas resulting from either islet tumors, insulary hypertrophy or neurogenic acceleration in the secretory activity of the islet cells. On the other hand, hypoglycemia may result not only from an excessive secretion of insulin by the pancreas, but from disturbance in the glycogen forming, as well as the gluconeogenic function of the liver, from abnormal activity of certain of the ductless glands, especially the adrenals and the anterior lobe of the hypophysis, and from certain wasting diseases. Clinically, the symptomatology resulting from these various morbific factors may be indistinguishable from those produced by the parenteral administration of an excessive amount of insulin.

* * *

II. SYMPTOMS

Eugene Ziskind, M.D. (2007 Wilshire Boulevard, Los Angeles).—The most accurate clinical knowledge of hypoglycemia was obtained after the discovery of insulin. Symptoms of insulin overdosage present a fairly typical picture, which for the greater part is characteristic for hypoglycemia, irrespective of its cause. In hypoglycemia due to pancreatic adenomas, the diagnosis of involvement of this organ is made by the exclusion of hepatic, pituitary, adrenal, thyroid and other endocrine symptoms and, finally, by laparotomy, since there are no specific pancreatic manifestations. The symptoms vary with the degree of hypoglycemia, as well as with the rapidity with which the blood sugar falls. There is no absolute blood-sugar level at which certain symptoms invariably occur. Occasionally severe symptoms appear with a relatively high blood sugar, and mild symptoms or none at all with a very low blood sugar, though on the whole the severity of the symptoms is a fair index of the blood-sugar level.

Early, mild symptoms include a sense of impending danger or uneasiness, hunger, restless-
18 ness, numbness, coldness, headache, drowsiness, apathy, weakness, tremulousness, and perspiration. Objectively, at this stage one usually finds tachy-
3 cardia, pallor, tremor, perspiration, and increased pulse pressure. Dilatation of the pupils may also be present. The tachycardia and increased pulse pressure reflect the greater cardiac output, compensating for the deficient supply of carbohydrate energy to the brain. Since the highest cerebral functions are affected first by deficient brain nutrition, it is not surprising that the incipient symptoms may appear in this sphere. Among the subtle, but early signs of hypoglycemia, is impairment of memory. In fact, in objective tests on three patients with hyperinsulinism, the first abnormality noted was a reduction in the auditory memory span. In a patient under observation at the present time, when the blood sugar was 68 milligrams per cent, his memory span was five digits; whereas, one-half hour after eating, his "span" was nine digits. Frequently, a very early indication will be a certain good-natured, euphoric or silly attitude, in which all remarks are punctuated with smiles or laughter. Or there may be an initial apathy with lack of spontaneous activity and speech, bland facial expression, and a poverty of ideas.

A whole gamut of nervous symptoms, including any focal neurologic finding, may subsequently appear. These may be present as transitory phenomena or may last for longer periods, in exceptional instances, up to several days. Paralysis may vary from a mild form of paresis to complete loss of movement, and may be in the nature of cranial nerve palsy, monoplegia, or even hemiplegia. Involuntary movements are relatively frequent, and very marked restlessness and wild tossing about are fairly common. There may be paresthesias, sensory loss, and aphasia. The mental state is frequently disturbed, findings varying from a mild confusion to marked acute manifestations such as mania, delusions, and hallucinations. There may be involuntary laughing, crying, or singing. Reflex changes, chiefly in the nature of increased deep reflexes, have been noted, and a positive Babinski toe response is not uncommon. The objective signs correspond to the symptoms mentioned, and an aggravation of the systemic abnormalities noted in the earlier manifestations. The temperature frequently falls and the drop may be quite marked. I have seen a very pronounced fall in temperature (down to 94 degrees) after injections of insulin. This symptom has considerable diagnostic significance and is not adequately stressed in clinical descriptions of this subject. On the other hand, low-grade fever has at times been recorded with hyperinsulinism.

Further progress of the hypoglycemia as the blood-sugar falls results in convulsions, coma, and finally death. It is of interest to note that convulsions following insulin overdosage may not be due to the low blood sugar. Hrubetz [1] reported that the injection of insulin in doses just sufficient to reduce the blood sugar to zero does not result in seizures. The dose required in rats was one-half to three-fourths units of insulin per kilogram of body weight. With larger dosage, so-called "shock" dosage, she did produce seizures. With one unit of insulin per kilogram of body weight, convulsions were obtained in 2 per cent of the animals tested; with four units convulsions occurred in 90 per cent. The author attributed the convulsions to an extrahypoglycemic factor. This work is emphasized because clinicians often ascribe the convulsions of epileptics to hypoglycemia when the fasting blood sugar is moderately reduced below 70 milligrams per cent. In fact we have shown [2] that insulin injected in quantities up to sixty units failed to reproduce seizures in epileptic patients, even when the blood sugar was below 45 milligrams per cent. Nevertheless, patients with hypoglycemia frequently present convulsions. In a patient with seizures the history of mild hypoglycemic symptoms preceding the attacks, variability in the attacks, and their occurrence a long time after meals, are very suggestive of hypoglycemia.

[2] Ziskind, E., and Bolton, Ruth: Insulin Hypoglycemia in Epileptics, Arch. Neurol. and Psychiat. (To be published.)

The individual symptoms of hypoglycemia are not at all specific. The proof of their origin depends on the demonstration of an associated low blood sugar. Inasmuch as the degree of hypoglycemia cannot be absolutely deduced from the clinical picture, it is necessary to test the blood sugar in the presence of symptoms. It is well known that at times a normal person may have a relatively low blood sugar. Hence a low blood sugar reading in itself is not diagnostic of clinical hypoglycemia. Before the diagnosis of hyperinsulinism is considered as established, clinicians should insist on the reproduction of hypoglycemic symptoms when the blood sugar is low and the disappearance of symptoms as the glycemic level is elevated. Fasting is the simplest and most readily available method for demonstrating hypoglycemia and its attendant signs.

Clinically, hyperinsulinism is manifested as a paroxysmal disorder. The blood sugar usually becomes elevated to normal after meals and remains so for two, three or more hours. Hence hypoglycemic symptoms tend to be present at the end of this time, *i. e.*, usually shortly before subsequent meals, or more frequently in the early morning hours, after the longest interval without food. Whether or not the blood sugar is depressed to a lower level by the carbohydrate in the diet than by the overnight fast is still an unsettled point. The early morning hours before breakfast were the most frequent for symptoms in our three patients with hyperinsulinism. Although hypoglycemic symptoms are usually of short duration, coma or confusion may last for longer periods if nourishment is not given. Food is not the only factor causing the termination of hypoglycemic attacks. Compensatory mechanisms may occasionally spontaneously overcome the hypoglycemia with disappearance of the symptoms. Following a convulsion in a patient with hypoglycemia, the blood sugar becomes elevated to normal. Failure to recognize this fact has led to the common error of ascribing a hypoglycemic origin to seizures when the blood sugar has been found normal after glucose was administered in the postconvulsive period.

In concluding, the following salient features about hypoglycemic symptoms may be stressed. The early findings are usually those explained on the basis of compensatory epinephrin effect, tachycardia, increased pulse pressure, pallor, perspiration, and dilated pupils. Later follow symptoms indicative of focal involvement of the central nervous system. The diagnosis of hypoglycemia should be withheld until the symptoms are reproduced in the presence of a low blood sugar. The symptoms are paroxysmal and occur at periods remote from eating. The diagnosis of pancreatic origin of the hypoglycemia, hyperinsulinism *per se*, is a matter chiefly of excluding other endocrine pathology and, finally, of exploratory laparotomy.

III.* HYPOGLYCEMIA

Fletcher B. Taylor, M.D. (400 Twenty-ninth Street, Oakland).—Hypoglycemia is a level of glucose in the blood which is low enough to be uncomfortable or dangerous. Amounts below 80 milligrams per hundred grams of blood may arbitrarily be included in the definition, since some individuals are uncomfortable at that level. Everyone has experienced the weak, trembly feeling that follows prolonged exertion on an empty stomach. This betokens a level somewhere near 80 milligrams per cent and as the level becomes lower still, definite weakness, faintness, and convulsions may result. Various individuals develop these symptoms at various levels, there being variable susceptibility to hypoglycemia among people. The speed of the drop in blood sugar probably also determines the amount of shock to the individual. During starvation treatment for diabetes there were quiet deaths from respiratory paralysis secondary to hypoglycemia, and without any preliminary convulsions.

It is in the care of diabetic patients that the problem of hypoglycemia is most practical. Starvation treatment is no longer in vogue, but insulin given hypodermically can cause a quick starvation of tissue and is thus even more capable of causing shock and death by hypoglycemia. We have also to deal with influences inside the body affecting the blood-sugar level. Pituitrin, thyroxin, and epinephrin raise the blood-sugar level. Insulin and parathormone decrease it. The pituitary action is probably not limited to that of pituitrin. An anterior lobe hormone represses formation of insulin, and its absence, as in adiposogenital dystrophy, conduces to hypoglycemia. Exercise decreases the blood-sugar level on the day of such exercise and sometimes even on the day following.

Insulin is the most intimate and necessary hormone in the control of carbohydrate traffic in the body. After food is absorbed and carbohydrate is negotiable in tissue fluids, insulin acts almost as a placement bureau. It deposits sugar in the liver when necessary; it releases it from the liver when needed elsewhere in the body and it may even assist in the oxidation of sugar once arrived at functioning tissues.

The various influences noted, and other known and unknown factors help control the amount of glucose in the blood, tending normally to balance and to keep the level within a zone of normal. Intake, assimilation, storage, mobilization, oxidation and excretion of glucose may vary its level in the blood.

A man who has very little food intake will tend to have hypoglycemia. If that man has poor digestion of starch because of defect in starch-digesting enzyme, there will be greater trend toward hypoglycemia. Assume that he has diarrhea with rapid transit of food through the small intestine which does not permit proper absorption. And imagine further that he has insufficient secretion of pituitrin, of thyroxin, and of adrenalin. Also add to his troubles a damaged liver, whether by atrophy, necrosis or by overgrowth with a neoplasm, so that he has insufficient storage space for reserve glycogen. Suppose, also, that our fictitious patient has too much insulin because of carcinoma of the islands of Langerhans; and that he is a Marathon runner, thus burning available carbohydrate rapidly. Then let us make his plight complete by assuming that the kidneys "leak" glucose, that the renal tubule cells are unable to conserve or reabsorb glucose. This one unlikely clinical example presents for our convenience a situation in which many known factors will all work in the direction of hypoglycemia. The converse picture need not be described and the possible variations are easily imagined.

---

* The works and writings of T. L. Althausen, Joslin, Samson Wright, and Zondek are gratefully acknowledged as the principal background for this report.

Hypoglycemia is sometimes seen in the newborn, and it happens in some people who are on diet fads. A woman who was a very active horseback rider and a light eater fainted and fell from her horse because of it. A drunken person is weak and trembly on the "morning after" partly because of hypoglycemia. A diabetic patient of mine developed hypoglycemic shock on the basis of unusual exercise plus strong catharsis. Patients with pituitary cachexia, with Addison's disease and with hypothyroidism tend to have hypoglycemia, because of hormonal insufficiencies characteristic of these conditions.

A patient with acute liver damage from alcohol, from carbon tetrachlorid, from cincophen or from phosphorus is liable to hypoglycemia if there is sudden demand for glucose, because such a person has reduced carbohydrate storage space. High-fat diet gluts the liver with fat and decreases its glycogen storage space.

Insulin injections start reducing blood glucose immediately, the action is maximal at forty-five minutes and continues for at least two and one-half hours. Variable speed of absorption of the tissues at the injection site may modify these time factors. Protamin insulin has its effect more slowly, and may still be at work twenty-four hours after injection. Repeated injections of insulin at intervals of two and one-half hours or less, or of protamin insulin at twenty-four hours or less, may cause cumulative action and danger of hypoglycemia. Glucose evokes insulin production by the pancreas. Sudden withdrawal of continuous flow of glucose solution into the vein leaves a phase of rapidly forming insulin with decreased material to work upon and may cause hypoglycemia. Furthermore, the liver of such a person becomes passive in the formation of glycogen. It comes to depend upon the glucose available by vein. Ordinarily the liver furnishes glycogen from the fat and protein available, but after intravenous glucose therapy, the liver has a latent period in which it forms glycogen from protein and fat more slowly than usual. This secondary effect is then added to the sudden lack of glucose through the needle, and both factors tend to lower blood sugar. Long-continued intravenous administration of glucose should, therefore, be tapered off, not suddenly stopped.

Measures for control of hypoglycemia may be listed herewith, although they are inferred above. For acute drop in blood glucose, feed some glucose or sugar, a piece of candy, plain or sweetened orange juice. Glucose by mouth has been found to cause an appreciable effect in as short a time as five minutes. Warm the patient as a measure against medical shock. If the patient cannot swallow, give subcutaneous epinephrin 0.5, which will have effect within twenty to thirty minutes. Secure and start glucose solution by vein while waiting.

Hypoglycemia may be recognized by the presence of one or more of the following symptoms: hunger, tremor, nervousness, weakness, sweating, mask face, vertigo, aphasia, delirium, convulsions, lowering of body temperature and of blood pressure. If the patient is unconscious, the various other causes for unconsciousness must be considered. In diabetic patients it is well to be certain that the condition is due to *low,* not *high,* glucose level. Absent acetone and diacetic acid in the urine, absence of acetone breath, low temperature, coolness of skin, sweating, abrupt unconsciousness, and convulsions speak for abnormally low glucose and help in the differentiation. If there is uncertainty, a blood sugar determination by the micromethod may be done. Its accuracy is sufficient for the emergency and the observation can be completed in a few minutes.

Public Schools: First Aid and Lawsuits.—It is the law of this state that boards of education, school districts and their officers, teachers and other employees are liable for damages resulting from injuries sustained on school property when due to the dangerous or defective condition thereof, or to negligence on the part of school officers or employees. Therefore, when an accident occurs, skill on the part of the individual who administers first aid is important. A serious injury should be cared for by the most skillful person available, preferably a physician or nurse. In the absence of professional assistance the school authorities will not be held liable if standard first-aid procedure is followed by the principal, teacher, clerk or other employee who cares for the injured person.

Recently the Board of Education and some of its employees have been made defendants in actions which involved the question whether school employees rendered adequate first aid. It is, therefore, extremely important that competent people on the staff of each school should be capable of giving adequate first-aid assistance. When qualified first-aid workers are available, the school physician's time may be conserved for the more highly skilled services for which he is primarily employed.

Special care should be given to all wounds. A first-aid antiseptic should be used and a sterile dressing applied. A wound seen by a school employee which is not covered and which becomes infected (regardless of how many days later the infection occurs) may be the cause of a troublesome lawsuit.

It is well to remember that first-aid may be used as an approach to a closer contact between the first-aid worker and the student. Many a principal, physician, nurse, and teacher has developed a most satisfactory teacher-pupil relationship as a result of the services rendered in connection with accidents and injuries on the school grounds.

First aid properly administered may also be a first-class method of health education. The care and skill used by the first-aid worker in putting on a dressing may be a never-forgotten lesson in health education which will have a distinct carry-over value into adult life. Sometimes the irritating interruptions of our routine work are really opportunities in disguise.—Los Angeles City School District, Health Section.

CALIFORNIA MEDICAL ASSOCIATION

This department contains official notices, reports of county society proceedings and other information having to do with the State Association and its component county societies. The copy for the department is submitted by the State Association Secretary, to whom communications for this department should be sent. Rosters of State Association officers and committees and of component county societies and affiliated organizations, are printed in the front advertising section on pages 2, 4 and 6.

MEMBERS, READ THESE COUNCIL MINUTES

Members are urged to read the following Council minutes.

COUNCIL MINUTES[†]

Minutes of the Two Hundred and Forty-Seventh Meeting of the Council of the California Medical Association

Held in the Lounge of the Los Angeles County Medical Association building, 1925 Wilshire Boulevard, Los Angeles, at 9:30 a. m. Saturday, September 26, 1936.

1. **Call to Order.**—The meeting was called to order by the chairman, Morton R. Gibbons, with the following members present: President Edward M. Pallette, President-Elect Howard Morrow, Speaker W. W. Roblee, Chairman Morton R. Gibbons, Chairman of Public Relations Committee C. A. Dukes, Councilors Calvert Emmons, Carl R. Howson, Henry J. Ullmann, A. E. Anderson, K. L. Schaupp, O. D. Hamlin, C. E. Schoff, Henry Rogers, H. H. Wilson, C. O. Tanner, William H. Kiger, T. Henshaw Kelly, J. B. Harris, Editor George H. Kress, Secretary F. C. Warnshuis, and General Counsel Hartley F. Peart. Dr. Clarence G. Toland was present by invitation.

Absent: Councilor Alfred L. Phillips on account of the serious illness of his mother.

2. **Executive Minutes.**—The Secretary stated that the minutes of the one hundred and forty-seventh meeting of the Executive Committee had been mailed to all councilors, and on motion of Councilor Kiger, seconded by President Pallette, the minutes of the one hundred and forty-seventh Executive Committee meeting were approved.

It was moved by President-Elect Morrow, seconded by Councilor Kelly, that the minutes of the Executive Committee meetings be printed in the JOURNAL in digest form and that said digests be prepared by the chairman of the Executive Committee and the secretary. Carried.

3. **Hall of Medical Science Exhibit.** — Clarence G. Toland, Chairman of the Committee on the San Diego Fair, presented a progress report on the exhibit, together with outstanding bills payable amounting to approximately $1,000, and stated that an effort was being made to have this balance settled by the Fair management, and that a final statement would be submitted by Doctor Kinney.

It was moved by President Pallette, seconded by Councilor Kiger, that the Executive Committee be authorized to pay the expense of the outstanding bills for the exhibit at the San Diego Fair, after approval by the Auditing Committee. Carried.

It was moved by President Pallette, seconded by Councilor Roblee, that the Secretary be authorized to prepare a suitable scroll in appreciation of the work done by the Committee on the San Diego Fair and that copies be sent to the San Diego Society and the members of the Committee.

It was moved by President-Elect Morrow, seconded by Chairman of Public Relations Committee Dukes, that a vote of thanks be accorded the California Medical Association's Committee on the San Diego Fair. Carried.

4. **Postgraduate Conferences.** — Clarence G. Toland, Chairman of the Committee on Postgraduate Conferences, outlined plans for future conferences, stating that a liaison had been arranged with the State Heart Association and the State Tuberculosis Association so that their speakers would be used in these conferences.

5. **Health Exhibit.**—Editor Kress outlined a plan of amending the State Library Act to permit of the use of the remaining funds allocated to the State Library for the preparation of a traveling Public Health Exhibit, under direction of the California State Board of Health, for use at the 1939 Golden Gate International Exposition and at subsequent state and county fairs.

It was moved by Chairman of Public Relations Committee Dukes, seconded by Councilor Emmons, that the general plan outlined by Doctor Kress of amendment of the State Medical Library Act to permit the use of the remaining funds for the establishment of a health exhibit, be approved. Carried.

6. **Order of Business.**—It was moved by Chairman of Public Relations Committee Dukes, seconded by Councilor Ullmann, that the Council continue in session until 5 p. m.

7. **Report of Committee on Public Relations Hospital Insurance.**—The report of the Committee on Public Relations on policy of the Association regarding hospital insurance was read and discussed in detail.

It was moved by Councilor Kelly, seconded by Councilors Hamlin and Dukes, that the Council approve the plan of the Insurance Association of Approved Hospitals and the inclusion in that plan of reimbursement for clinical pathologic services and x-ray services for diagnostic purposes only.

A vote was then taken on the motion: 17 ayes; Doctor Wilson voted in the negative. Motion carried.

It was moved by Councilor Schoff, seconded by Councilor Harris, that the Council approve the plan of the Intercoast Hospitalization Insurance Association and the inclusion in that plan of reimbursement for clinical, pathological, and x-ray services for diagnostic purposes only. Carried.

---

[*] All articles listed under this caption, "This Month's Topics," have been written and sent to the editor by the Association Secretary, Dr. Frederick C. Warnshuis.

[†] The minutes of the two hundred and forty-sixth meeting of the Council of the California Medical Association were printed in the July, 1936, issue of CALIFORNIA AND WESTERN MEDICINE, page 97.

8. **Corporate Practice.**—The General Counsel read the proposed letter on corporate practice prepared in accordance with Resolution No. 8, adopted by the House of Delegates at Coronado, and gave a résumé of the present statutes covering this type of practice.

It was moved by Councilor Wilson, seconded by Chairman of Public Relations Committee Dukes, that a copy of the letter be sent to each county secretary with the request that it be read at the next meeting of the Society; that copies be sent to all hospitals and sanitariums; and that the letter be published in the JOURNAL for the information of all members. Carried.

9. **Code Commission.**—After discussion of the necessity of constant vigilance in the recodification of the Medical Practice Act, and of medical and health laws by the California Code Commission, it was moved by Editor Kress, seconded by Councilor Kelly, that a subcommittee, consisting of the Chairman of the Council, the President-Elect of the Association, the Secretary, the Chairman of the Legislative Committee, and the General Counsel, be appointed to handle the whole matter of recodification of medical and health laws and that it be authorized to secure the assistance of an attorney at Sacramento and to expend the necessary funds, subject to approval by the Auditing Committee. Carried.

10. **Legislation.** — Doctor Harris, Chairman of the Legislative Committee, submitted a progress report on pending and contemplated legislation.

11. **Hospital Insurance.**—After full discussion of hospital insurance, it was moved by Councilor Kelly, seconded by Councilor Ullmann, that a committee of three members of the Council be appointed by the Chairman to study and develop a form of state-wide organization to furnish hospital and/or medical care on a periodic basis; to formulate legislation if found necessary; and to report to the Council not later than November 1, 1936.

The Chairman appointed Councilors Kelly, Kiger, Chairman of Public Relations Committee Dukes, and F. F. Gundrum.

12. **Noon Recess.**—At this point a recess was declared for luncheon.

13. **Call to Order.**—The Council was called to order by Chairman Gibbons, after the noon recess, with the following members present: Doctors Pallette, Morrow, Roblee, Gibbons, Emmons, Howson, Ullmann, Anderson, Schaupp, Rogers, Wilson, Tanner, Kiger, Kelly, Harris, Dukes, Warnshuis, Schoff, Hamlin, Editor Kress, Counsel Peart. Absent: Doctor Phillips.

14. **Committee on Survey of Expenditures.**—Doctor Schoff, Chairman of the Committee on Survey of Expenditures, stated that he was not ready to submit his final report and requested that this be made an item of business for the next meeting of the Council.

15. **Appeal Hearings.** — General Counsel Peart submitted briefs of the California Medical Association in the matter of the appeals of Ferd Callison, et al., San Francisco, and Joe Smith, et al., Kern County, before the Judicial Council of the American Medical Association.

The Secretary stated that Doctor Elbridge Best would represent the Council in the San Francisco appeal and that Louis Packard would represent the Council in the Kern appeal and that Chairman of the Public Relations Committee Dukes would act in an advisory capacity in both appeals.

The Secretary presented requests from the San Francisco and Kern County societies for payment of the expense incurred by Doctors Best and Packard, representing the Council in appeals before the Judicial Council of the American Medical Association.

It was moved by Councilor Kiger, seconded by Councilor Kelly, that the expense incurred by Doctors Best and Packard in representing the Council in the appeal hearings before the Judicial Council of the American Medical Association in Chicago be paid; it being understood that no precedent is established thereby. Carried.

16. **Legislative Program.**—The General Counsel suggested the advisability of preparing a definite legislative program for the next legislative session. Mr. Peart suggested that the following amendments to the Medical Practice Act be prepared in consultation with the Attorney-General's office, to be used, if found necessary, by the Legislative Committee: (*a*) Express exclusion of corporate practice; (*b*) express inclusion of radiology, clinical pathology and anesthesiology; (*c*) exclusion of delegation of professional duties to laymen; amendment to forbid advertising of fixed fees. Mr. Peart also suggested that amendments should be prepared relating to the definition of indigency; amendments to the Non-Profit Hospital Service Act; and amendments to the Code of Civil Procedure to provide for reasonable compensation for opinion evidence.

It was moved by President Pallette, seconded by President-Elect Morrow, that a committee of two be appointed to confer with the State Board of Medical Examiners regarding proposed legislation in which they are interested and report back to the Executive Committee. Carried.

17. **Physician's Handbook.**—The proposed outline of a physician's handbook was presented and it was stated that it would be well to publish this in CALIFORNIA AND WESTERN MEDICINE and furnish reprints to physicians.

It was moved by Chairman of Public Relations Committee Dukes, seconded by Councilor Rogers, that the physician's handbook as outlined by the General Counsel, the Editor, and the Secretary, be approved and that they be instructed to undertake its preparation. Carried.

18. **California Forestry Medical Corps.** — The attention of the Council was called to a telephone communication and correspondence received by the Editor relative to an article appearing in the JOURNAL regarding the Forestry Medical Corps. Doctor Warnshuis stated that the article contained a true statement of facts and that the Medical Corps had been reorganized and that during the Los Angeles and San Diego fires only members of the Forestry Medical Service of the California Medical Association were permitted to serve.

19. **Drugless Practitioners.**—The attention of the Committee on Legislation was called to the fact that the drugless practitioners were endeavoring to secure licenses as physicians and surgeons and their own licensing board.

20. **Qualifying Certificate Act.** — Editor Kress stated that the Committee on the Qualifying Certificate Law was at present working on the law and would report at a later date.

21. **Paper for Publication in Journal.**—The attention of the Council was called to the violation of Sections 4 and 5 of Chapter VII of the by-laws of the Association by a member who had permitted a paper much like one presented at the Coronado session to be published elsewhere without permission of the Publications Committee.

It was moved by Editor Kress, seconded by Councilor Kelly that the matter be referred to the chairman of the Committee on Scientific Work for investigation. Carried.

22. **Roster of Association Members.**—It was moved by Editor Kress, seconded by Councilor Ullmann, that hereafter the roster of members be published in December of each calendar year and that the roster for 1936 be published in the December, 1936, issue of the JOURNAL. Carried.

23. **Contraception.**—It was the sense of the Council that no policy relating to contraception be adopted until the American Medical Association declares its attitude upon this question and that, therefore, the subject be not given space in our official publication.

24. **Paper for Journal.**—Discussion of the publication of a series of papers by one author on recent studies in industrial medicine was acted on by the following motion:

It was the sense of the Council that if the author desired to prepare the papers the Publications Committee would give them consideration and determine whether they would be accepted for publication.

25. **Articles in Journal.**—On motion of Editor Kress, seconded by Councilor Kelly, it was

RESOLVED, That articles appearing in CALIFORNIA AND WESTERN MEDICINE be not released to business firms for advertising and publicity purposes and that authors be advised that ownership of these papers passes to the Association under the rules governing publication and the provisions of the copyright law.

26. **Dues of Association.**—It was moved by Editor Kress, seconded by Councilor Emmons, that it is the sense of the Council that editorial comment should be

made in order to transmit to all members the reasons and circumstances that created the necessity for an increase in Association dues for 1937. Carried.

27. **Annual Conference of County Secretaries.**—The Secretary presented a tentative program for the annual conference of county secretaries and officers.

It was moved by President Pallette, seconded by Speaker Roblee, that the annual conference of county secretaries and officers be held in San Francisco during the first week of February and that the travel expenses of county secretaries be paid by the Association. Carried.

28. **Legislative Coöperation.**—Letters from the State Board of Health and State Board of Medical Examiners signifying their willingness to coöperate in legislative matters of mutual interest were presented by the Secretary for the information of the Council.

29. **Reinstatement of Members.** — It was moved by Councilor Ullmann, seconded by Councilor Rogers, that members whose dues have been accepted by county secretaries since April 1, 1936, be reinstated to membership in the California Medical Association. Carried.

30. **Financial Statement.**—On motion of Councilor Ullmann, seconded by President-Elect Morrow, and carried, the financial statement for the month of August, 1936, was approved.

31. **Medical Society of the State of California.**—After discussion of the value of membership in the medical society of the State of California, it was moved by Chairman of Public Relations Committee Dukes, seconded by President Pallette, that the Secretary and the Editor be instructed to prepare, with the guidance of the Legal Counsel, an outline of a talk to be given by councilors at county society meetings in their respective districts, and that a letter to members imparting the advantages of membership in the medical society of the State of California be prepared by the Secretary. Carried.

It was the sense of the Council that a standing "ad" be run in the Journal advising members of the advantages of membership in the medical society of the State of California, and that a column citing typical cases and experiences be inaugurated in the Journal, under the supervision of the Editor and the General Counsel.

32. **Relation of Malignancy and Trauma.**—It was moved by Chairman of Public Relations Dukes, seconded by Councilor Schaupp, that the institution of a study on relationship between malignancy and trauma, as ordered by Resolution No. 6, adopted at Coronado by the House of Delegates, be referred to the Cancer Commission in conjunction with the Committee on Industrial Practice for report and recommendation to the Council. Carried.

33. **Cancer Commission.** — Doctor Dukes, Chairman of the Cancer Commission, stated that the Cancer Commission desired to make a further study of the cancer problem and moved that $500 be allocated to the Commission for clerical work and further education of the medical profession and the laity and for revision of the report of the Cancer Commission. The motion was seconded by Councilor Ullmann. A vote was then taken: 4 ayes; 9 noes. Motion defeated.

34. **Arrangements Committee.** — The Secretary reported that Chairman Gibbons had appointed as members of the Arrangements Committee, J. A. Merrill, Monterey, Chairman; Mast Wolfson, Monterey; Paul M. Hunter, Carmel; H. Spencer Hoyt, Monterey; and E. F. Kehr, Carmel, Secretary. The Arrangements Committee as appointed by the Chairman was approved by the Council.

35. **Trustees of the Indemnity Defense Fund.**—On nomination duly made and ballot duly cast, Howard Morrow was elected as trustee for the Indemnity Defense Fund, term expiring in 1937.

On nomination duly made and ballot duly cast, Junius B. Harris was reëlected as trustee for the Indemnity Defense Fund, term expiring in 1939.

36. **Death of William Duffield.** — It was moved by Speaker Roblee, seconded by Councilor Howson, that the Secretary prepare a suitable resolution on the death of William Duffield and that a copy of the resolution be sent to the bereaved family and inscribed in the minutes of this Association, and that when the Council adjourn it do so in the memory and respect of William Duffield. Unanimously carried by a rising vote.

William Duffield, M.D.

1866-1936

No matter when it comes, at the beginning or zenith of a career, death is an unwelcome guest. We try to understand the meaning and the loss of a fellow associate, but our thoughts become subdued as we see the vacant chair and the empty forum, and only realize that our associate is no longer in our midst.

On September 9, 1936, William Duffield heard the summons from beyond the Great Divide and stepped out into the night and wandered on into an unknown land.

The Council of the California Medical Association, on behalf of the membership, therefore adopts the following resolution by a rising vote on September 26, 1936.

Whereas, William Duffield's life labors are ended, it is earned recognition to record that he has served fellow practitioners and this Association in the discharge of official duties for many years as a member of the Council; and

Whereas, In his relations with his fellow man he was kindly, helpful and generous, in his professional work he was an ethical and scientific practitioner of the healing art, and in his relations to organized medicine he was an enthusiastic worker for the upholding of the standards of medicine and the promotion of the highest aims of medical art and science; now therefore be it

Resolved, That in the death of Dr. William Duffield the public has lost a true friend, the members of the medical profession a much-beloved coworker, and organized medicine and the members of the Council of the California Medical Association a true and faithful servant of medicine; and be it further

Resolved, That a copy of this resolution be spread upon the minutes of the Council, a copy be printed in California and Western Medicine and a copy sent to his bereaved family.

37. **County Hospitals.**—It was moved by Speaker Roblee, seconded by President-Elect Morrow, that the following resolution, as adopted by the Riverside County Medical Association, be approved by the Council:

Whereas, The recent decision of the California Appellate Court makes it permissible for the supervisors of the county to admit to the Riverside County Hospital part-pay patients as well as indigents; and

Whereas, The members of the Riverside County Medical Association, in conjunction with the resident staff, have heretofore been responsible for and assumed the care of indigent patients at the Riverside County Hospital; and

Whereas, All services by the visiting staff have been rendered gratuitously; therefore be it

Resolved, That the Riverside County Medical Association go on record as objecting to the care of part-pay patients who are financially able to make arrangements for private hospital care; and further be it

Resolved, That all admittance of part-pay patients to the Riverside County Hospital be submitted for review to a representative or representatives of the Riverside County Medical Association by the Social Service Department of Riverside County; and be it further

Resolved, That the Council of the California Medical Association endorse these resolutions and/or offer a plan of procedure that will adequately define the relation of the members of the California Medical Association to county hospitals.

A vote was then taken on the resolution. Motion carried. Doctor Dukes voted in the negative.

38. **Anesthetics Case.**—The following letter, prepared by the Auditing Committee, outlining the financial responsibility of the anesthetists and the Association in the case of *Francis* vs. *Nelson* and clarifying the matter of printing and legal costs, was read to the Council.

It was moved by Councilor Schaupp, seconded by Councilor Kelly, that the letter as presented together with the recommendations contained therein be approved. Carried.

To the Council of the California Medical Association,
San Francisco.

Gentlemen:

The Auditing Committee, as directed by the Executive Committee at its meeting on August 15, 1936, has reviewed the matter of the finances of the *Francis* vs. *Nelson* case in Los Angeles County and submits the following report for the consideration of the Council.

The original agreement made with Dr. Chalmers-Francis, representing the anesthetists, and the Council, when he appealed to the Council for aid after obtaining an adverse decision in the case begun independently of the Council, provided:

1. Council agreed to appropriate $750 for expenses and $750 for legal services of its own in obtaining a decision

in the case, the understanding being that the legal counsel of the California Medical Association would be responsible for the conduct of the case after the appropriation of this money.

2. The anesthetists agreed to contribute $750 toward the costs of appeal.

3. The anesthetists agreed that if costs exceeded these amounts they would reimburse the California Medical Association in any amount above the original appropriations.

Investigation of the facts show that many of the statements made in Dr. Chalmers-Francis' letter of July 24 are not according to the record.

1. The brief that Dr. Chalmers-Francis had printed (in galley proof only) in Los Angeles for $152.15 had not been approved by Mr. Peart as agreed upon and lacked the printed testimony from the record and which was used in the brief. This is required by law, and required 146 pages additional. Therefore, Doctor Chalmers-Francis' statement that the difference in cost between printing in San Francisco and Los Angeles was $544.43 minus $152.15 is unwarranted.

2. When the closing brief was ready for printing, estimates were obtained in both cities, and on January 14, 1936, Attorney Anderson of Los Angeles wrote to Mr. Peart: "I feel that since the expense is practically the same, you had better have the brief printed there, and direct you to do so."

3. The statement that the printing could have been done for $179 is, therefore, manifestly not true.

Thus, the Auditing Committee recognizes that the debt of $450 is a perfectly legitimate one under the original agreement with the Council and is not subject to any of the criticisms referred to above.

If the Council wishes to do so, however, the Auditing Committee suggests that, in order to close the finances of the case and to meet the anesthetists part way at least, it abrogate the terms of the original agreement, accept the check for $179 and charge the $271 remaining as the price of a resolution. The resolution should be to assume no further litigation which may be started by enthusiastic members with the hope that, if it does not proceed successfully, the California Medical Association will carry on.

Respectfully submitted,
THE AUDITING COMMITTEE.
(Signed) Karl L. Schaupp, M. D., *Chairman.*
O. D. Hamlin, M. D.
T. Henshaw Kelly, M. D.

39. **Woman's Auxiliary.** — It was moved by Speaker Roblee, seconded by Councilor Kelly, that the Woman's Auxiliary be granted the sum of $150 for expenses at the 1937 annual session at Del Monte. Carried.

40. **Telephone Listings.**—Letter from H. S. Hunsberger protesting listings in the Telephone Directory under the heading "Laboratories and Medical X-Ray," was presented.

In view of the fact that the matter of telephone listings is under the control and direction of the State Railway Commission, on motion of President-Elect Morrow, seconded by President Pallette, the Secretary was instructed to reply to Doctor Hunsberger advising him of the past experience of the Association and its unsuccessful efforts to regulate these listings. Carried.

41. **Date of Council Meeting.**—It was moved by President Pallette, seconded by Councilor Schoff, that the next meeting of the Council be held on the Sunday following the annual conference of county officers, *i. e.*, February 7, 1937.

42. **Hospital Insurance.**—It was moved by Councilor Harris, seconded by Councilor Kelly, that the Council reconvene at 10 a. m. Sunday morning, September 27, for the consideration of hospital and/or medical service plans. Carried.

43. **House of Delegates Procedure.**—Councilor Howson brought up the matter of procedure in presenting resolutions to the House of Delegates.

After discussion, it was moved by President Pallette, seconded by Councilor Kelly, that a Committee of Three prepare and present to the House of Delegates amendments to the by-laws, providing for an increase in the number of reference committees and sessions of the House of Delegates during annual sessions. Carried.

44. **Adjournment.**—At this point the Council rose in silent tribute to Doctor Duffield, and adjourned in respect of his memory.

MORTON R. GIBBONS, *Chairman.*
F. C. WARNSHUIS, *Secretary.*

DIGEST OF ONE HUNDRED FORTY-SEVENTH EXECUTIVE COMMITTEE MEETING

Held August 15, 1936.

Legislation was discussed and plans outlined for presentation to Council.

Council's answering brief to appeals pending before the American Medical Association was arranged for.

Hospital insurance rider was referred to Committee on Public Relations for report at September Council meeting.

General Counsel was instructed to draft letter in accordance with Resolution No. 8 adopted at Coronado.

Secretary, Editor, and General Counsel were instructed to prepare syllabus of proposed legal handbook for Council consideration.

Suggestions of plans to increase membership of medical society of the State of California were referred to the Council.

Reprints of revised Constitution and By-Laws were ordered.

Council meeting fixed for September 26, 1936, in Los Angeles.

KARL L. SCHAUPP, *Chairman.*
F. C. WARNSHUIS, *Secretary.*

* * *

SUNDAY, SEPTEMBER 27, 1936

The Council, in accordance with a motion made by Councilor Harris, convened at 10 a. m. for the discussion and consideration of hospital and medical service plans and legislation proposed by several lay groups and organizations.

The subject was presented by Doctor Harris who tersely outlined and analyzed in great detail the present trend of legislation and proposed solutions as they relate to medicine and medical care.

Every councilor, President Pallette, President-Elect Morrow, and Editor Kress engaged in the discussion, thereby presenting the views of members in every councilor district.

At 1:00 p. m., after three hours of special deliberation, the Council adjourned, after instructing the special committee to be guided by the facts that had been presented.

F. C. WARNSHUIS, *Secretary.*

* * *

THE UPPER SACRAMENTO TREK

Dr. Clarence G. Toland, during his term as president, was the first officer who undertook to visit as many county societies as possible during his presidential year. Last year President Robert A. Peers established a record by visiting every county society. These officers were accompanied by the councilor in the district that was visited and by the State Secretary. Because of the number of societies and the large area covered by their districts, Councilors C. E. Schoff and Henry S. Rogers contributed the most time to the making of these visits.

In general, the purpose of these visits is to meet with the members of each county society, to gain an insight of local conditions, to discuss policies and activities and to impart an insight as to state activities. Keen interest was manifested in every unit. Members gained information as to what a united association was accomplishing in their behalf and perceived new value in their membership. As a result we are witnessing a wholesome renewal of activity and state-wide interest in our Association affairs. Our purposes of organization are being attained in greater degree.

Ours is a vast state. These visits consume a large amount of time that is contributed by our presidents in behalf of all members. Last year President Peers and the Secretary traveled 20,603 miles by automobile and nearly 4,000 miles by train to make these visits. Wonder if the officers of any other state covered any such area.

On October 8, President Pallette set out on his 1936-1937 trek of visits to county societies. He was accompanied by President-Elect Morrow, Councilor C. E. Schoff, and the Secretary. Meetings were held with the Yolo-Colusa-Glenn Society at Woodland, a breakfast conference in Sacramento, Yuba-Sutter at Marysville, Butte at Chico, and Tehama and adjacent societies at Red Bluff.

Sunday was consumed in driving back to San Francisco, where President Pallette boarded the train arriving in Los Angeles Monday morning.

Every meeting was inspiring by reason of large attendance, the interest exhibited and the questions, comments and discussions that characterized these meetings. A splendid spirit exists among these upper Sacramento Valley societies, and their officers and committees are alert in their discharge of official duties. We point with pride to all of our county societies.

Itineraries have been made for visits to other regions in the State before our annual session in May.

* * *

PERSONS PER PHYSICIANS

Physician-population relationship studies uncover some interesting and thought-provoking figures.

In California there is one physician to 519 people, in comparison with Rhode Island 1 to 737, South Dakota 1 to 1,196, and South Carolina 1 to 1,541. In New York's Manhattan Borough 1 to 287, Boston 1 to 290, Washington, D. C., 1 to 297. In San Francisco the ratio is 1 to 345, and in Los Angeles 1 to 384.

While reports indicate that the ratio of physicians to population is decreasing, there is no complaint as to scarcity of physician's services. Good roads and hospital facilities permit the obtaining of adequate care. However, the steadily increasing migration to and location in centers of population and metropolitan areas, with their higher office and living expenses, may compel eventually the relocation of physicians in rural areas.

* * *

CLUB DUES VERSUS MEDICAL SOCIETY DUES

Ever and anon a complaint is received in regard to medical society membership dues. As a rule the complaining member is a member in name only, he attends his county and state meetings on rare occasions and is possessed of little information as to what is being done in defense of his profession or to prevent outside encroachment on his practice and livelihood. By non-attendance he neglects opportunities to improve his professional ability and standards of practice.

When questioned it is found that the complainant is a member of several clubs and lay social organization. He pays from $75 to $150 for the privilege of playing golf. Dues of $60 to $125 are paid for admission to a club where he can pay 85 cents to $1.25 for his noon lunch, an hour of bridge, billiards or checkers, and say "Howdy" to the banker, lawyer or merchant Pooh Bah of his town. He readily remits $50 to $100 per year to some luncheon club where he can sing the "old songs," be called Jack, and listen for thirty minutes to some imported speaker describe how a can is made in six operations from one small piece of tin. Then there is the lodge, church, fishing or skeet club, and possibly one or two other lay organization. All told, his nonmedical organizations tap him for from $200 to $400 for yearly dues. His medical society dues averages from $20 to $50 per year—the average being about $25 per year.

Criticism is not directed against membership in these organizations, provided income permits. Criticism is directed against such membership when complaint is made, "we are paying too much for what we get." That claim is challenged because facts exist to disprove that statement. The trouble is that this member has never taken the pains to ascertain or acquire the full benefits or membership in his county medical society. He can secure the facts by reading the editorials and Association activities columns in the preceding twelve issues of CALIFORNIA AND WESTERN MEDICINE. For value received a physician obtains more from his medical dues than he obtains from his dues paid to nonmedical organizations. The value of returns is so great and membership benefits so vital that an eligible physician cannot afford *not* to be a member.

* * *

A MEDICAL RACKET

Six times as many patients sued their doctors in 1935 as in 1921. Present conditions indicate that in this year one doctor in twenty will become a defendant in a malpractice suit.

The situation is one in which lawyers and designing patients conspire to obtain fees. Certain members of the legal profession seem to have a bend that impels them to distort and enlarge facts and advance most unreasonable claims and frame-ups in their quests for financial income. Patients are more damage-minded and have little difficulty in obtaining a lawyer to accept their case. The situation is becoming more and more serious all over the country. We are being impelled to undertake defensive measures to expose and end this lawyer-patient racket. It is a racket because, of suits coming to trial, only five per cent result in a verdict against the doctor. However, only a small percentage come to trial, as the "making of a settlement" is sought and often agreed to by the insurance company.

Pending the termination of this racket, members are urged to join the medical society of the State of California, thereby securing a personal attorney who will protect your personal interests and rights and joining with the insurance carriers' counsel, every effort will be made to protect you and defeat unjust claims.

Membership application blanks may be secured from the State Secretary.

* * *

COUNTY SECRETARIES' CONFERENCE

The Council has designated Saturday, February 6, 1937, as the time for holding the annual conference of county secretaries in San Francisco.

These conferences were inaugurated last year. Their value has been determined, hence their continuance.

In due time announcements will be made of the program and full details sent to every secretary. Mark the date in your engagement book.

C. M. A. DEPARTMENT OF PUBLIC RELATIONS†

Costs of County Hospitals

Recent press reports state that a grand jury in San Joaquin County declared: "Uncovered a condition in the highway department, in the road districts, and in the county hospital . . . that points to unlawful and high-handed procedure of long standing." The report states: "There is no escape from fraud and favoritism in county purchasing until the county provides its own charter."

Commenting on the pay-patient system in the county hospital, the report states: "The pay-patient system appears to have been honeycombed with supervisorial patronage. We find the name of one supervisor, as well as the names of other persons, who have received treatment as pay patients and who never have paid." The report recommends steps be taken to install a more effective system of collections from pay patients at the hospital and states the record shows the names of many who have never made any effort to meet their obligations. Of course the taxpayers paid the bill in their taxes.

That these practices on the part of county hospitals and supervisors do increase taxes and operating costs, is evidenced by these figures from Kern County. Last year *90 per cent* of the people in Kern County who required hospitalization were hospitalized in the county hospital. It is difficult to conceive that 90 per cent of Kern County residents are indigent. Ever increasing costs are evidenced by these figures: In 1921 the cost was $44,634. In 1931, $212,493, a 400 per cent increase, with a population increase of 50 per cent. In 1932 the cost was $240,102; 1933, $251,934; 1934, $266,078; 1935, $365,647. These figures do not include costs for the tuberculosis sanitarium. For 1936 the budget provides $372,197.

In contrast, San Bernardino County can be cited where in two years the county hospital costs have been reduced from $346,404 to $239,857, a saving of $106,547, or 30 per cent, of the taxpayers' money.

---

† The complete roster of the Committee on Public Relations is printed on page 2 of the front advertising section of each issue. Dr. Charles A. Dukes of Oakland is the chairman, and Dr. F. C. Warnshuis is the secretary. Component county societies and California Medical Association members are invited to present their problems to the committee. All communications should be sent to the director of the department, Dr. F. C. Warnshuis, Room 2004, Four Fifty Sutter Street, San Francisco.

A few more grand jury reports in other counties might be inspired in the interest of taxpayers and the removing of county hospitals from the control of supervisors and placing them under an institutions commission. In Sacramento the charter provides: "The Sacramento County Hospital shall be maintained for county indigents only." As the local paper states: "This leaves the door wide open to admit all the deserving. But closes it tight to undeserving chiselers such as those who in San Joaquin County apparently pass on their medical costs to the taxpayers."

* * *

Unfair Practices

There are some detail salesmen, by reason of a "peeve" because some physicians will not grant an audience or see them, who resort to a whispering campaign by means of which they utter reflections and undermining comments about that doctor to other doctors, and even lay individuals. We recently encountered such pettiness.

We are certain that the firms employing these salesmen do not condone or tolerate such practices. We are also certain that when salesmen indulging in spite practices are reported to the sales manager that they will be dealt with as they deserve. This Association's central office will appreciate members reporting these tale-bearing salesmen in order that their conduct can be reported to their employers.

* * *

Legislative Influence

By way of introduction, the following quotations are presented:

Edward L. Bernays said: "As civilization has grown more complex, the transmission of ideas has been quickened. As competitive forces have multiplied and sharpened, it has become increasingly apparent to all groups that they must win and obtain public approval if they are to survive in the welter of competitive forces struggling for public favor."

And Bruce Barton warned business men to cease spending so much time fighting political demagogues and governmental meddling and more time winning the favor of people.

Our legislative influence and power is dependent upon the degree in which we enlist public opinion and public favor. To win that favor and support it is necessary to engage in a sustained campaign that utilizes certain measures that may be designated as technique.

Mac F. Cahal has said that our legislatures, as we know them, are a government of minorities, of high-pressure tactics and private motives. That every law is the result of a mobilized group—a unit of force. Our scheme of organization provides that mobilized unit and force, provided that we remain cohesively united and active. Our high pressure shock troops can be and are enlisted by County Legislative Committees. We have mobilization methods that will generate pressure power if we guide our movements.

Public approval is best obtained by working through existing public guilds, Parent-Teacher and similar organizations. In approaching these groups there must be a predetermined form of appeal. Some form of psychology should be decided upon, for experience has demonstrated the value of employing psychological persuasion. As Cahal recommends, "If we have a bill for compulsory vaccination we will appeal to parental love. For a basic science law we must appeal to fair play." Greatest results are obtained by emotional appeals. Literature containing emotional appeals, by actual tests, has been found to be remembered three times as long as literature that presented actual data.

Next come symbols. To refer to a bill as a proposed law creates little interest and arouses little support. Again quoting Cahal: "Baby Health Bill will be more effective than vaccination law, and health-protection bill will be more effective than basic science law."

Medicine for self-preservation must win and hold public favor. To do this no opportunity should be lost to present to individuals and groups the ideals and policies of our profession. Demonstrations of our sincere, unselfish, and constructive purposes for man's physical welfare must continue unceasingly along the widest avenues of public approach. Every member should recognize the part he must assume. Without that coöperation our legislative influence will sink into ineffectiveness.

Having secured public favor and support, one more activity is necessary. Your senators and assemblymen are to be contacted and informed as to what measures are endorsed and the measures which are opposed and that the recommendations made have the endorsement, favor, and support of their community. These representatives must be made to realize that it is incumbent upon them to act accordingly. By so doing, the pressure is applied—without application all effort is for naught.

When every county unit recognizes and follows this technique, our legislative influence will function for not only our good, but for the greatest good of all who live in this great commonwealth. We shall shortly be confronted with the necessity of exhibiting our influence when the legislature convenes. Therefore, begin now to secure public favor!

* * *

Immunization Suggestion

It is recognized that every physician should extend his professional services to include preventive medicine. Failure to do so creates the necessity for health officers to step in and engage in the practice of preventive medicine. If health officers are invading the field of medicine in your community, the reason lies in the fact that physicians are not practicing preventive medicine and are negligent in providing immunization measures for their patients.

County societies should take steps to correct this neglect and to urge every member to cause all of his patients and families to be protected by preventive methods. An eastern county medical society has adopted a form letter and urges its members to address the communication to the families whom they serve.

The form is as follows:

————, 193——

Dear Mrs. ————:

Our records show that a child whom you named ———— was born six months ago. We know that you desire to give ———— every opportunity for health and strength, and we wish to remind you that this is the time to give the simple treatment which will protect ———— against diphtheria.

Diphtheria is a serious disease for young children, so serious that the protective treatment should be given now. The Medical Society of the County of ————, of which I am a member, is coöperating with the state and local Departments of Health, and has asked me to send this message to you urging that unless your child has already been protected you may have this important matter taken care of.

————————, M. D.,

You have no justified complaint against your health department if you fail to practice preventive medicine.

COMPONENT COUNTY MEDICAL SOCIETIES

HUMBOLDT COUNTY

The Humboldt County Medical Society met on the evening of August 6 at the Eureka Inn, with President J. S. Woolford presiding. Twenty members were present. Dr. Edwin I. Bartlett of San Francisco was the guest speaker.

The Society went on record as being in favor of the State Association increase in dues from $10 to $15. Immediately our local dues were raised $5.

Doctor Bartlett, with the aid of films, presented a very interesting paper on *Bone Tumors*, which was widely discussed by Doctors Markel and Norman.

* * *

The Humboldt County Medical Society met on the evening of September 3, with a dinner at the Humboldt County Tubercular School. The president, J. S. Woolford presided. Dr. Philip H. Pierson of San Francisco was the guest speaker.

Doctor Pierson's address was on the subject *How Every Doctor Should Participate in a Tuberculin Testing Campaign.* This paper was very interesting and widely discussed.

LAWRENCE A. WING, *Secretary.*

MARIN COUNTY

The regular monthly meeting of the Marin County Medical Society was held on September 24, with a good attendance. Dr. G. M. Landrock, a former member, who is now practicing proctology in San Francisco, gave a very interesting and educational talk on his specialty. He presented many good slides which were most interesting to the general practitioner.

C. W. CLARK, *Secretary.*

MONTEREY COUNTY

The regular October meeting of the Monterey County Medical Society was held at the Forest Hill Hotel, Pacific Grove, on October 1.

Amendment of the by-laws of the Society in regard to disciplinary procedures was unanimously carried, thereby placing members under the disciplinary code of the State Association.

The applications for membership of Dr. Howard E. Clark of Monterey and Dr. Edwin M. Chase of Soledad were accepted.

The secretary reported the action of a committee planning an exhibit at the Monterey County Fair on October 8, 9, 10 and 11, and upon motion duly made and seconded, this action was properly endorsed by the Society.

Doctor Merrill reported that upon an ordinance passed by the County Board of Supervisors any member of the county society may admit patients directly to the County Hospital for emergency purposes. Other admittances must be passed upon by the Welfare Department of the county.

Doctor Spencer Hoyt presented case reports of urologic cases, with x-rays and lantern slides, and followed with a review of the anatomy of the prostate gland. Dr. Lawrence M. Knox presented a case of extensive ulcerative colitis, with the x-rays and necropsy specimens. Dr. Edwin F. Kehr presented the literature and case reports on the use of protamin insulin.

E. F. KEHR, *Secretary.*

SACRAMENTO COUNTY

The regular meeting of the Sacramento Society for Medical Improvement was called to order by President Frank MacDonald at the auditorium on Twenty-eighth and L streets on September 15. There were fifty-five members and guests present.

Dr. J. B. Harris presented the case of a middle-aged white woman suffering from recurrence of an adenocarcinoma of the left breast for which radical mastectomy had been performed seven years ago. Visible metastases in the axillary region had appeared five and one-half years after operation. The interesting feature of this patient was the extreme size of the left arm and forearm, caused by obstruction of the lymphatics by the tumor tissue. This patient required from 15 to 20 grains of morphin sulphate daily for the pain occasioned by the malignant invasion of the brachial plexus.

The speaker of the evening, Dr. Edmund Butler, chief surgeon of the Emergency Hospital Service of the City of San Francisco, was introduced by the president. Doctor Butler spoke on *Injuries of the Chest and Abdomen That May Cause Early Death, and the Diagnosis and Treatment.*

Chest or abdominal injuries and their complications occur largely in industry and as a result of automobile accidents. These may result in sudden death, or death may follow regardless of treatment. Ten per cent of all deaths due to chest injuries may be prevented. Many wounds of the chest and abdomen are caused by shattering of the steering wheel in automobile accidents, with penetration by the spokes. There may be multiple fractures of the bones of the thoracic wall, with contusions and lacerations of the lung and chest wall. This may be accompanied by either open or closed pneumothorax, hemothorax, hemorrhage from intercostal arteries, complete fracture of the sternum, or puncture wounds of the lungs due to depressed rib fragments. In addition to treating these patients for shock, which is nearly always present, Doctor Butler stressed the importance of controlling hemorrhage from intercostal arteries by suturing around the entire contiguous rib if necessary. Closing an open pneumothorax, due to a puncture wound, may be done by suturing the soft parts if possible, or by sealing rubber tissue over the opening. The aspiration of air may relieve the pressure in the closed type of pneumothorax. The presence of pneumothorax embarrasses respiration through displacement of the mediastinum with impairment of function of the contralateral lung. Elevation of depressed rib fragments may be accomplished by means of towel clips, and complete fractures of the sternum with depression are well relieved by extension and traction with towel clips also. Puncture wounds of the chest with lung hemorrhage may be controlled with packing through a proctoscope. Subcutaneous emphysema causing distress may be relieved by incision where it is superficial. Cardiac lacerations when diagnosed must be repaired. Traumatic diaphragmatic hernia must also be treated surgically when the patient's condition permits. Pneumonitis may develop as the result of severe chest injuries, and the speaker advocated the use of 10,000 units of polyvalent-anaerobic serum as a safeguard against anaerobic infection plus the use of 3,000 units of tetanus antitoxin.

All individuals involved in accidents must be watched carefully for symptoms of abdominal injuries since these may not appear for two hours and may be delayed from six to eight hours in those suffering from alcoholism. Pain and shock, or vomiting, are not always present early, and the presence or absence of liver dullness is not reliable. The respiratory movement of the abdomen may be restricted. Two most helpful measures in diagnosing abdominal injuries are: x-ray which will reveal air under the diaphragm when a hollow viscus is ruptured; second, the instillation of sodium iodid into the bladder, which will reveal bladder injury. Marked renal bleeding may be detected by x-ray films, which often reveal obliteration of the psoas muscle on the affected side. Hemorrhage cannot always be diagnosed by laboratory means since blood dilution does not often occur until the patient has reacted from shock and dehydration. Tears of the liver may be treated by simple suturing or packing. Lacerations of the spleen may require splenectomy.

Dr. Garnett Cheney of San Francisco was asked by Doctor Butler to discuss the blood changes that occurred after splenectomy following injury to that organ. He stated that there is increase in the platelets and leukocytes, and drop in the red blood cells, accounting for the anemia that occurs. The inhibitory factor of the bone marrow upon platelets and leukocytes is lost, the hemoglobin falls more than the red blood cells because of removal of iron pigment, and the endothelial cells are removed, thus tending to prevent the body from putting iron in the red blood cells in pigment form. It takes months after splenectomy for the lymph glands, liver, and bone marrow to compensate for the loss of the endothelial cells. These patients should be given large doses of iron after splenectomy since it will help to correct the anemia.

Doctor Butler's paper was discussed by Doctors Woolsey, Beach, and Topping.

The application of Doctor Soracco for membership in the Society was read for the first time.

The report of the Board of Directors was read for the meetings of July, August, and September. Doctor Hale called the secretary's attention to an omission in the reading of the minutes of the July Board of Directors meeting.

A letter from Dr. Rulon S. Tillotson was read.

NORRIS R. JONES, *Secretary.*

SAN BERNARDINO COUNTY

The annual meeting of the San Bernardino County Medical Society was held at the California Hotel, San Bernardino, on Tuesday, October 6. About sixty-five members and guests were present. Dinner was served at 7 p.m. The meeting was opened by the president at 8 p.m.

Election of officers:

It was moved and seconded that the Society be instructed to cast a unanimous ballot for the following officers: D. C. Mock, president; Frank Pritchard, first vice-president; W. E. Macpherson, second vice-president; and A. E. Varden, secretary-treasurer.

Passed and so ordered.

Information has just been received that Doctor Macpherson has moved to Los Angeles and has applied for transfer to the Los Angeles County Medical Society. This vacancy in the office of second vice-president is to be filled by the Board of Directors at their next meeting.

The secretary-treasurer then gave the financial report as approved by the Council.

Dr. V. M. Pinkley explained that physicians doing office work for the county on a part-pay plan will be legally liable to attend these patients in the home, and quoted his authority for the statement. The Advisory Board invited an expression from the Society before starting the plan. The fund set aside for the purpose might be transferred to the depleting obstetrical fund if not used for office work.

After further discussion Dr. P. M. Savage, Jr., moved that the Society recommend to the Advisory Board that the fund for office work be transferred to the obstetrical fund. Seconded and carried.

The following new members were voted on and approved: Doctors Emmett Forde Kesling of Trona, Ernest Cadwell of Fontana, Francis L. Crowley of Patton, Theophilus Fleming Ford of Ontario, Frances Franklin of Ontario, and Joseph M. Swindt of Chino by transfer.

The program of the evening was then given as follows:

Pioneers of Medicine in the San Bernardino Valley.

T. M. Blythe, M. D., of Redlands, 1891.

Marie A. Bennette, M. D., of San Bernardino, 1885.

Joseph A. Champion, M. D., of Colton, 1898.

John N. Baylis, M. D., of San Bernardino, 1888.

William A. George, M. D., of Loma Linda, 1911 .

These talks by the pioneers were most interesting and entertaining. Unfortunately, Doctor Evans of Highland was unable to be present.

After a short talk by our councilor, Dr. C. L. Emmons, the meeting adjourned at 10 p. m.

A. E. Varden, *Secretary.*

SAN JOAQUIN COUNTY

The regular meeting of the San Joaquin County Medical Society was held in the Medico-Dental clubroom in Stockton. The meeting was called to order at 8:25 p. m., Dr. T. C. O'Connor presiding.

The regular meeting was preceded by the customary supper meeting at the Hotel Wolf, at which nineteen members and guests were present. Dr. Dewey Powell spoke on *European Impressions,* and particularly emphasized the splendid equipment of the *Queen Mary.*

The petitions of Drs. R. A. Greenman and Daniel Beltz for membership in the San Joaquin County Medical Society were passed on favorably by the Admissions Committee. There being no objections from the floor they were declared members.

Dr. A. L. Van Meter, as chairman of the Committee on the Postgraduate Study, announced the opening of a new session in this study and urged all members to participate in this undertaking.

The paper of the evening was presented by Doctor Laurence Taussig, associate professor of dermatology, University of California, who gave a talk, illustrated by lantern slides, on *Common Skin Diseases and Their Treatment.* The paper dealt mainly with the pustular infections, with special emphasis on impetigo. The paper caused considerable discussion from the floor.

There being no further business to come before the Society, the meeting was adjourned at 9:45 p. m. and refreshments were served.

G. H. Rohrbacher, *Secretary.*

TULARE COUNTY

The Tulare County Medical Society held its first fall meeting on Sunday, September 6, at Motley's Café in Visalia at 6:30 p. m., preceded by dinner.

Following the schedule approved for "Order of Business" in the recently voted by-laws, the educational program was presented first.

Dr. J. C. McClure, president, presided and introduced Dr. T. L. Althausen, associate professor of medicine at the University of California. Doctor Althausen read a paper on *Recent Advances in Diagnosis and Treatment of Gall-Bladder Disease.*

He stressed particularly the newer physiologic concept of the biliary-hepatic system, and with this background discussed the various disturbances of gall-bladder function and also the treatment of choliocystic disease.

A round-table of discussion followed his paper which was thoroughly appreciated by those present.

In routine business session the accumulated correspondence of the past summer was summarized for the members. The new code of disciplinary procedures was read and is to be added to our by-laws by vote at our next regular meeting.

The question of postgraduate courses was referred to the committee for discussion at the next meeting.

Karl F. Weiss, *Secretary.*

CHANGES IN MEMBERSHIP

New Members (21)

Los Angeles County.—Carl Erich Ebert.

Marin County.—Edward V. Knapp.

Orange County.—Burr J. Van Doren.

Riverside County.—Omer W. Wheeler.

Sacramento County.—Charles V. Soracco.

San Diego County. — Parker Hollingsworth, Henry Marcus Young.

San Francisco County.—Leonard G. Dobson, Max Fine, Morris R. Gordon, Arthur Haim, Edward Lee Harrington, Harold H. Lindner, Walter W. Port, David A. Rytand.

San Joaquin County. — Daniel Beltz, Robert Alvin Greenman, Henry C. Rixford.

San Luis Obispo County.—Edison A. French.

Santa Barbara County.—Harold Kahn.

Ventura County.—Harold S. Foskett.

Transferred (2)

Eric Liljencrantz, from Alameda County to San Francisco County.

Joseph Swindt, from San Francisco County to San Bernardino County.

In Memoriam

Allen, John. Died at Raymond, October 4, 1936, age 70. Graduate of Georgetown University School of Medicine, Washington, D. C., 1908. Licensed in California in 1914. Doctor Allen was a member of the Fresno County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

+

Beattie, Hugh. Died at Elk Grove, September 18, 1936, age 70. Graduate of Cooper Medical College, San Francisco, 1896, and licensed in California the same year. Doctor Beattie was a member of the Sacramento Society for Medical Improvement, the California Medical Association, and the American Medical Association.

+

Langnecker, Harry Leslie. Died at Palo Alto September 23, 1936, age 58. Graduate of Johns Hopkins University School of Medicine, Baltimore, 1906. Licensed in

California in 1915. Doctor Langnecker was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

+

Liliencrantz, August. Died at Oakland, October 9, 1936, age 89. Graduate of Rush Medical College University of Chicago, 1870. Licensed in California in 1882. Doctor Liliencrantz was an honorary member of the Alameda County Medical Association, the California Medical Association, and the American Medical Association.

+

Newman, Henry Parker. Died at San Diego, September 23, 1936, age 83. Graduate of the Detroit Medical College, 1878. Licensed in California in 1908. Doctor Newman was a retired member of the San Diego County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

+

Offield, Archibald Leonard. Died at Burlingame, September 17, 1936, age 59. Graduate of Cooper Medical College, San Francisco, 1905, and licensed in California the same year. Doctor Offield was a member of the San Mateo County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

+

Thieme, Derk Anthony I. Died at Los Angeles, October 5, 1936, age 54. Graduate of the University of Southern California School of Medicine, Los Angeles, 1905, and licensed in California the same year. Doctor Thieme was a member of the Los Angeles County Medical Association, the California Medical Association, and a Fellow of the American Medical Association.

THE WOMAN'S AUXILIARY TO THE CALIFORNIA MEDICAL ASSOCIATION[†]

MRS. ANDREW J. THORNTON..............................President
MRS. ROBERT M. FURLONG..Editor

Notes From the National Organization

It is the purpose of the Woman's Auxiliary to the American Medical Association to promote health education, and it is the purpose of the Committee on Health Education and Program to promulgate and assist the state and county auxiliaries in their programs. A more sympathetic and broader knowledge is necessary to obtain the best results.

From the recommendations to the Woman's Auxiliary to the American Medical Association by Mrs. V. E. Holcombe, National Chairman of Health and Program, Charleston, West Virginia, the following excerpts are taken:

The aims of the Woman's Auxiliary should be kept before the auxiliaries, and the responsibility of each state and county chairman shall be to work out a health program which is approved by her Advisory Council, which will meet the needs of her respective state and county.

The American Medical Association Radio Broadcasts.—Plans are under way by the American Medical Association for broadcasting programs on health topics during the winter months. Doctor Bauer has requested that the Auxiliary continue in building up a listening audience throughout the coming year. Announcements will be sent to you from time to time concerning these splendid programs.

Collection of *Hygeia* clippings are available for borrowing; these clippings may be kept ten days, and the borrower must pay return postage. Doctor Bauer writes: "Clipping loan collections are for the lay individual who wishes to write a paper or make a talk on health to lay audiences." Loan collections are available on the following subjects:

330.1	Anesthesia
92.1	Anemia
346.1	Animal Experimentation
318.1	Athletics
124.3	Boys
184.1	Constipation and Cathartics
47.1	Communicable Diseases in the Home
121.1	Deafness
124.1	Delinquent Child
74.1	Diabetes
10.1	Diphtheria
322.1	Doctor
322.1	Doctor Bills
322.1	Doctor, Country
120.1	Eyes, Children's
327.1	Family Medicine Chest, The

9.1	Whooping Cough
42.1	Worms
335.1	X-Ray

[†] As county auxiliaries of the Woman's Auxiliary to the California Medical Association are formed, the names of their officers should be forwarded to Mrs. Robert M. Furlong, chairman of the Publicity and Publications Committee, Linden Lane, San Rafael. Brief reports of county auxiliary meetings will be welcomed by Mrs. Furlong and must be sent to her before publication takes place in this column. For lists of state and county officers, see advertising page 6. The Council of the California Medical Association has instructed the editor to allocate two pages in every issue for Woman's Auxiliary notes.

"Reference for Papers on Outstanding Women" in medicine may also be had for those who wish to write papers or to make a study on this subject.

Your national chairman has in her files a complete list of references on many subjects for those who are doing intensive study on any of these subjects and will be glad to send reference material upon requests on the following subjects.

These lists have been furnished by the Bureau of Health and Public Instruction of the American Medical Association.

Subjects for Study:

Adolescence
Alcohol
Allergy
Amebic Dysentery
Books Containing a Discussion of Anesthesia
Bacteriology
Doctor and Medical Practice
Deafness
There's a Doctor in the Story
Diabetes, Birth Control
Biology
Diet-Food-Nutrition
Child Guidance
Birth Injury
Climate
Hygiene
Industrial
The Preschool Child
Contagious Diseases
The Common Cold
Diseases of Children
Height, Weight
Age Tables for Children

County Auxiliary Reports

Los Angeles County.—The first fall meeting of the Woman's Auxiliary to the Los Angeles County Medical Association was held on Tuesday, September 22, at the County Medical building, with the new president, Mrs. Clifford Andrews Wright, presiding. The 118 members attending were served a delightful buffet luncheon at tables bright with autumn blooms, arranged by the new Flower Committee.

An announcement was made that the class in parliamentary law will be resumed next month. Resolutions, presented by Mrs. James F. Percy, on the death of Dr. William Duffield, a former president of the Los Angeles County Medical Association, were adopted.

Three-minute talks on pending legislation were given by Dr. William Daniels and by Mr. Ben Read.

The chief speaker of the program was Dr. Frank Davis of the department of psychology at the University of California at Los Angeles, who gave a very interesting outline of the psychologic significance of dreams.

* * *

The State Board of the Woman's Auxiliary to the California Medical Association met at the Casa Del Mar Club in Santa Monica on August 11, at which time the members of the Los Angeles auxiliary were asked to meet the state president, Mrs. Thornton, and the members of the State Board at luncheon.

The luncheon tables were attractively arranged with vivid centerpieces, and each place was marked with a small corsage.

Swimming and bridge were offered for relaxation between meetings.

* * *

The Los Angeles auxiliary announces with deep regret the untimely death of Mrs. Charles S. Young of Glendale on August 6.

⁂

Marin County.—The Woman's Auxiliary to the Marin County Medical Society held its first fall meeting of the year on Thursday evening, September 24, at the Marin Golf and Country Club, San Rafael. There were twenty-seven present, two of whom were guests.

The officers of the Marin County auxiliary for the coming year are: Mrs. Harry Hund of San Rafael, president; Mrs. Thomas Gocher of Fairfax, vice-president; Mrs. Roy R. Robertson of Sausalito, secretary; Mrs. A. Miller of San Rafael, treasurer.

After dinner the meeting was called to order by the new president, who gave a brief outline of her plans and aims for the year. Interest and enthusiasm was shown by the members present.

Following the usual reports and business transactions, Mrs. Hund appointed her committees for the year, to be headed by the following chairmen: Memberships and Organization, Mrs. Thomas Gocher of Fairfax; Program and Health, Mrs. Lloyd Tyler of San Rafael; Public Relations, Mrs. W. P. Goddard of Mill Valley; Publicity, Mrs. Roy R. Robertson of Sausalito; Entertainment, Mrs. M. E. Hazeltine of San Rafael; Transportation, Mrs. W. S. Polland of San Rafael; Historian, Mrs. Frank Cannon of San Rafael; *Hygeia,* Mrs. Thomas Gocher of Fairfax.

Mrs. Robert M. Furlong was presented with a gift as a token of appreciation for her services in the capacity of president for the past year.

The guest speaker of the evening was Mrs. Helene Hjort, who gave a most interesting and lucid picture of Java and life in the Dutch East Indies.

⁂

Orange County.—More than twenty-five members of the Woman's Auxiliary to the Orange County Medical Association met yesterday for the first time this fall at the home of Mrs. Harry G. Huffman, 2340 Riverside Drive.

The Huffman home was beautifully decorated with dahlias of all varieties, sent from the famous dahlia gardens of Dr. and Mrs. G. Emmett Raitt.

Mrs. K. H. Sutherland, new president of the group, conducted a short business meeting, at which she introduced her new fellow officers, including Mrs. D. C. Cowles of Fullerton, vice-president; Mrs. L. E. Wilson of Santa Ana, treasurer; and Mrs. G. E. Raitt of Santa Ana, secretary.

Mrs. E. H. Kirsten of Anaheim, Program Chairman, introduced Mr. Ben Read, executive secretary of the Public Health League, who discussed pending legislation. Miss Kate Rea of Anaheim, southern district chairman of education of the Federated Women's clubs, also spoke briefly on proposed amendments.

Other prominent guests introduced to the doctors' wives included a group of San Diego women, all medical auxiliary officials. They were: Mrs. A. J. Thornton, state president; Mrs. W. H. Newman, state corresponding secretary; Mrs. T. J. Lindemulder, president of the San Diego auxiliary; and Mrs. C. E. Howard, past president of the San Diego auxiliary.

At the conclusion of the afternoon's program, Mrs. Huffman served a delicious tea course, with the assistance of her co-hostesses, Mrs. Dexter Ball, Mrs. R. C. Harris, Mrs. K. H. Sutherland, and Mrs. G. E. Raitt.

⁂

Santa Clara County.—The Board of Directors met previous to the regular meeting to (*a*) pay bills; (*b*) elect a new corresponding secretary; (*c*) fill a vacancy on the board, one member resigning; (*d*) hear the report of the chairman of the Auditing Committee.

The regular meeting was a luncheon held at the San Jose Country Club, forty-two members being present.

After routine business was disposed of, Mrs. Shepherd gave a report of the State Board meeting held in Santa Monica in September.

The guest speaker of the day was Mrs. William P. Butler who spoke on *Impressions of Moden Medical Literature.*

MRS. CHARLES MOORE, *Secretary.*

Six in Operations Case Sentenced*

Six of eleven persons recently convicted as members of a Coast illegal operations ring today were under sentence of from four to twenty-five years in San Quentin prison.

The sentences of the other five were not fixed by Superior Judge Arthur Crum, who yesterday granted them permission to file applications for probation and set a hearing for November 16.

The six who were given prison terms also asked probation, but their pleas were denied by Judge Crum. Those sentenced were Dr. George Watts, 10 to 25 years; Dr. Jesse C. Ross, 10 to 25 years; Dr. Valentine St. John, 4 to 10 years; Dr. James Beggs, 10 to 25 years; R. L. Ranklin, 10 to 25 years, and William Byrne, 10 to 25 years.

All except Dr. St. John had been convicted on five counts, while he was found guilty on two counts. Each of the counts called for a penalty of from two to five years, and in all cases Judge Crum ruled that they must be served consecutively. Notices of appeal were filed by all six sentenced men.

Those granted permission to apply for probation were J. O. Shinn, John Creeth, Grace Moore, a nurse; Lillian Wilson and Violet Pelligrini.

Trials of the eleven persons lasted four weeks, and resulted from a series of raids in San Francisco, Oakland, San Jose, Los Angeles, Hollywood, Long Beach, and San Diego offices of the asserted syndicate.—Los Angeles *Herald-Express*, November 3, 1936.

In spite of all our advances in medical knowledge, it is still true that it is more important to know what sort of patient has a disease than what sort of disease a patient has.—James J. Walsh.

Bequest Forms: Unto the California Medical Association*

FORM OF CLAUSE OF WILL PROVIDING FOR CASH BEQUEST

I hereby give and bequeath unto Trustees Of The California Medical Association, a nonprofit corporation of California, the sum of $——— to be known as the ——— Gift, to be used and expended by said corporation for scientific, educational, or hospital purposes.

* * *

FORM OF CLAUSE OF WILL PROVIDING FOR CASH BEQUEST

I give and bequeath unto Trustees Of The California Medical Association, a nonprofit corporation of California, the sum of $———, to be held as a fund, to be known as the [here insert name desired] Fund, the principal whereof shall from time to time be invested to the best advantage compatible with safety, and the income whereof shall be used and applied for scientific, educational, or hospital purposes.

* * *

FORM OF CLAUSE OF WILL PROVIDING FOR BEQUEST OF PERSONAL PROPERTY

I give and bequeath unto Trustees Of The California Medical Association, a nonprofit corporation of California [here describe the property], the same, or the proceeds thereof, to be held as a perpetual fund, to be known as the [here insert name desired] Fund, the income whereof shall be used and applied for scientific, educational, or hospital purposes. The said corporation shall have the power to sell said property and to invest and reimburse the proceeds arising from the sale thereof from time to time as it may deem advisable for the purpose of producing as large an income as may be compatible with safety.

* * *

FORM OF CLAUSE OF WILL PROVIDING FOR DEVISE OF REAL PROPERTY

I give and devise unto Trustees Of The California Medical Association, a nonprofit corporation of California, to aid and further its scientific, educational, and hospital purposes, and to be known as the ——— Gift, the following described real property situate in the County of ———, State of California, and more particularly described as follows, to wit:

* * *

FORM OF CLAUSE OF WILL PROVIDING FOR DEVISE OF REAL PROPERTY

I give and devise unto Trustees Of The California Medical Association, a nonprofit corporation of California [here describe the property], the same, or the proceeds thereof, to be held as a perpetual fund, to be known as the [here insert name desired] Fund, the income whereof shall be used for and applied to the support and maintenance of scientific, educational, or hospital purposes. The said corporation shall have the power to sell said property and to invest and reinvest the proceeds arising from the sale thereof from time to time as it may deem advisable for the purpose of producing as large an income as may be compatible with safety.

The key to the world of the future and to the wise fraternity of all races lies in the liberation of the child from the bondage of others' error and sin; from disease and debility, from desertion and want, from ignorance and passion above all, that are visited on the helpless to the third and fourth generation. The heart of a child is friendly to all; like the baby of Della Robbia, its limbs are bound, but its arms go out to its fellows. Its single claim is to be allowed to love; its one revenge to die if, for an hour, we neglect it.—Romain Rolland.

---

*Editorial comment is made on page 380; other news items concerning the trial are given on page 448, in State Medical Board column.

* These Bequest Forms were discussed editorially in CALIFORNIA AND WESTERN MEDICINE, for March, 1936, p. 145, and June, 1936, p. 460.

MISCELLANY

Under this department are ordinarily grouped: News Items; Letters; Special Articles; Twenty-five Years Ago column; California Board of Medical Examiners; and other columns as occasion may warrant. Items for the News column must be furnished by the fifteenth of the preceding month. For Book Reviews, see index on the front cover, under Miscellany.

NEWS

Coming Meetings

American Medical Association, Atlantic City, New Jersey, June 7-11, 1937. Olin West, M. D., 535 North Dearborn Street, Chicago, secretary.

California Medical Association, Del Monte, May 2-5, 1937. F. C. Warnshuis, M. D., 450 Sutter Street, San Francisco, secretary.

* * *

National Society for the Prevention of Blindness, Columbus, Ohio, December 3-5, 1936. Mr. Lewis H. Carris, 50 West Fiftieth Street, New York, managing director.

Southwestern Medical Association, El Paso, Texas, November 19-21, 1936. Orville E. Egbert, M. D., 116 Mills Street, El Paso, secretary.

Medical Broadcasts*

American Medical Association

The American Medical Association and the National Broadcasting Company present the second series of dramatized health broadcasts under the title "Your Health," beginning October 13. The first broadcast in the new series will be the thirty-second dramatized coöperative broadcast. The theme for 1936-1937 will differ slightly from the topic in the first series, which was "Medical Emergencies and How They Are Met." The new series will be built around the central idea that "one hundred thousand American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve the American people in sickness and in health."

The program will be on the Red network and Pacific network of the National Broadcasting Company. The stations listed below are those on the Pacific Coast to which the program is available:

KPO—San Francisco
KFI—Los Angeles
KGW—Portland, Oregon
KOMO—Seattle, Washington
KHQ—Spokane, Washington

It should be noted that a station may take the program or not. If a station included in the list is not broadcasting the program "Your Health," it is possible that the management may be induced to broadcast the program if it receives evidences of local interest. The Committee on Education or other appropriate committee of the county medical society might take this matter up with the station management and tender coöperation in giving the program local publicity.

The time of the broadcast is Tuesday afternoon, two o'clock, Pacific time.

* * *

San Francisco County Medical Society

A radio broadcast program for the San Francisco County Medical Society for the month of November is as follows:

Tuesday, November 3—KYA, 6 p. m.
Tuesday, November 10—KYA, 6 p. m.
Tuesday, November 17—KYA, 6 p. m.
Tuesday, November 24—KYA, 6 p. m.

Los Angeles County Medical Association

The radio broadcast program for the Los Angeles County Medical Association for the month of November is as follows:

Tuesday, November 3—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, November 7—KFI, 9 a. m. Subject: The Road of Health.
Saturday, November 7—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, November 10—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, November 14—KFI, 9 a. m. Subject: The Road of Health.
Saturday, November 14—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, November 17—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, November 21—KFI, 9 a. m. Subject: The Road of Health.
Saturday, November 21—KFAC, 10:15 a.m. Subject: Your Doctor and You.
Tuesday, November 24—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, November 28—KFI, 9 a. m. Subject: The Road of Health.
Saturday, November 28—KFAC, 10:15 a. m. Subject: Your Doctor and You.

Lane Lectures of 1936.—Stanford University is pleased to announce that the twenty-sixth course of Lane Lectures will be given by Dr. Eugene F. DuBois on April 5 to 9, 1937. The general title for the series of lectures will be "Mechanism of Heat Loss and Temperature Regulation."

Doctor DuBois is professor of Medicine at Cornell Medical College and medical director of the Russell Sage Institute, and is an experienced scientist in pathological physiology as well as in clinical medicine.

International Labor Office: Handbook on Industrial Medicine.—The large number of requests for information in the field of industrial medicine which have been received in recent years by the International Labor Office of Geneva, Switzerland, have resulted in publication by the Office of a handbook, or vade-mecum, designed specially for the use of physicians and others interested in that field.

The handbook contains a detailed report on the methods of investigation that medicine derives from other sciences—particularly from physics and chemistry—for the purpose of checking or testing atmospheric pressure, temperature, humidity, ventilation, lighting conditions, the quantity and nature of dusts and harmful gases and fumes, etc., in working premises.

Each chapter has been prepared by a recognized expert, and these experts have made a point of including methods and apparatus in different countries, while, however, selecting for presentation only such as, in their opinion, are most currently adopted or more generally recognized as best.

The main object in the preparation of the handbook was not to produce a learned "treatise" setting forth and criticizing theories and providing a voluminous bibliography, but merely to give practical information in an essentially concise form, without sacrificing clarity, so that the work might reach the largest possible public.

Produced in pocket-form, the handbook, containing some 330 pages, can be easily carried about the factory, workshop, etc., by any person whose task it is to ascertain that the hygienic conditions are satisfactory. The novice, as well as the trained observer, will find in it information calculated to assist him in his researches. The numerous diagrams and tables in the manual also should prove of value.

---

* County societies giving medical broadcasts are requested to send information as soon as arranged (stating station, day, date and hour, and subject) to CALIFORNIA AND WESTERN MEDICINE, 450 Sutter Street, San Francisco, for inclusion in this column.

Dr. Roy W. Hammack.—Roy W. Hammack, M. D., of Los Angeles recently became associated with Don Baxter (Incorporated) as medical adviser.

The Southern California Medical Association.—The semi-annual meeting was held at the Los Angeles County Medical Association headquarters, 1925 Wilshire Boulevard, Los Angeles, on October 30 and 31. The guest speaker was Dr. Elliott P. Joslin of Harvard Medical School.

Heart Disease in San Francisco Is Subject of Study. While the incidence of rheumatic heart disease treated by private practice in San Francisco is approximately the same as in the large eastern centers, it is definitely lower in clinic practice than is the case in these same eastern centers. Another point in San Francisco's favor is that many of the cases treated migrated to the bay region because of hoped for beneficial results from the milder and more equitable climate of this region.

These facts are set forth in an extended study of heart disease statistics in San Francisco by Dr. J. C. Geiger, San Francisco health officer; Dr. J. J. Sampson, assistant clinical professor of medicine, University of California Medical School; Dr. Roslyn C. Miller and Dr. J. P. Gray. The outpatient clinics of the University constituted one of the chief sources of the study, which also included a city-wide survey.

The study is reviewed in the current issue of the *American Heart Journal.*

The relatively low incidence of clinical cases of rheumatic heart disease in San Francisco is attributed to "better living conditions in poorer homes" than may be found in the other cities mentioned in the survey.

Symposium on Heart Disease.—The Heart Committee of the San Francisco County Medical Society will hold its seventh annual postgraduate symposium on heart disease on November 18 and 19, 1936.

The program includes the following:

WEDNESDAY, NOVEMBER 18

Morning Session—San Francisco Hospital
J. Marion Read, M. D., presiding

Presentation of patients with cardiovascular disease—subacute bacterial endocarditis, aneurysm, etc.

Afternoon Session—Stanford University Hospital
William W. Newman, M. D., presiding
Dr. William W. Newman presiding

Atypical Features of Coronary Occlusion. Illustrative Cases—Arthur Bloomfield, M. D.

Surgical Treatment of Hypertension—Emile Holman, M.D., and David A. Rytand, M. D.

Some Cases Erroneously Treated for Coronary Artery Disease—William Dock, M. D.

The Value of the Blood Sedimentation Rate as an Aid to the Diagnosis and Treatment of Coronary Occlusion—Henry Gibbons, III, M. D.

Management of Chronic Auricular Fibrillation. Illustrative cases—J. K. Lewis, M. D.

Evening Session—University of California Hospital
William J. Kerr, M. D., presiding

Round-Table Discussion (program in preparation).

THURSDAY, NOVEMBER 19

Morning Session—University of California Hospital
William J. Kerr, M. D., presiding

Clinics and Lectures (program in preparation).

Afternoon Session—San Francisco Hospital
Gordon E. Hein, M. D., presiding

Clinical pathological conference and demonstration of electrocardiograms.

Evening Session—San Francisco County Medical Society
J. Marion Read, M. D., presiding

Annual meeting of the San Francisco Heart Committee. Dr. John C. Ruddock of Los Angeles, President of the California Heart Association, will be the guest speaker and will give an illustrated lecture. Dr. Eugene S. Kilgore will discuss the cardiac cripple in industry.

Programs will be mailed on request as soon as completed. All those desiring to register for the course, please notify the secretary, Dr. William Dock, 604 Mission Street, Room 802, San Francisco. The registration fee is $2 for the entire course, which also entitles the registrant to membership in the newly organized California Heart Association.

Soft Foods Will Develop Race of Facial Weaklings. The public is conscious of the great achievements of science, but eagerly and innocently accepts the pseudoscientific statements blazoned forth in advertisements of nostrums and cure-alls. Unfortunately, both medical and dental practitioners, in some instances, have lent their names, sometimes inadvertently, but usually for gain, to this class of propaganda.

These statements are made in a paper on the professional relationship of the medical doctor and the dentist, written by Dr. William J. Kerr, head of the department of medicine of the University of California Medical School, and published in the current issue of *Annals of Internal Medicine.* The publication is the official organ of the American College of Physicians.

In his article Doctor Kerr stated that the modern tendency to use prepared and predigested foods is no doubt giving rise to faulty development of the face, jaws, and teeth through lack of use. "The pap which is served us from the cradle to the grave will make of us a race of facial weaklings," he said. "Infants should have something to masticate as soon as they have the tools to do so and probably require something firmer than milk to aid in the proper development of jaws and teeth.

"The heavy metals entering the body by accident or intent as therapeutic agents are frequently causes of destructive lesions in the supporting structures of the teeth. Mercury is notorious for its action in causing salivation and the loosening of the teeth. Lead, bismuth, and copper likewise cause local damage. Radium and other radioactive substances are dangerous to the bones of the jaw and other local tissues. Arsenic, when applied locally, may cause necrosis of local structures. Iron is frequently used in the treatment of anemia, and it is well known that loss and discoloration of teeth may result."

Tests Show New Insulin Compound Better Than Old.—A new insulin compound, developed by Danish scientists, with indicated advantages over the usual insulin from the standpoint of both dosage amount and absorption, has been tried on a group of diabetic children at the University of California Hospital here "with most encouraging results." The compound is a combination of the usual insulin with a protamin, a substance derived from the sperm of a species of trout (Salmo iridus).

"While still too early to give final pronouncement regarding protamin-insulinate, experience thus far with six children of the pediatric department at the University of California Hospital is most encouraging," the report from the hospital states. "It would seem to be of the greatest value in those children whose diabetes necessitates three or four injections of insulin in twenty-four hours, for it is found that injections can be cut down to not more than two in twenty-four hours, with maintenance of a blood sugar much nearer normal and subject to less fluctuation (neither too high nor too low) than with the four injections of the old insulin.

"In addition, there is more economy and less wastage of insulin, such that the total unit amount of insulin is materially reduced, averaging a little more than half the previous dosage. Considering the reduction in the number of injections which must be given aseptically, this reduces both the dread of the needle and the danger of infection—items of particular importance to the young patient. The cost item may likewise prove less if sources of protamin are not too costly, since there is the reduced amount of insulin." . . .

However, extreme caution is imposed on both diabetes sufferers and administering physicians, it being emphasized by the department that the treatment is still in the experimental stage. "Great care must be exercised in switching to or in starting the new insulin," the report said. "The danger of immediate substitution may lead to too low a blood sugar. So far the best results are obtained when a mixture of old and new insulin are used and the dosage finally fixed after four to ten days' observation and trial. It would seem logical that some insulin for immediate use (the old insulin), with some for slow absorption and gradual use would be the best treatment so long as the hormone product must be given by periodic injection."

Dean Chandler Gives Opening Lecture at University of Southern California.—The "Opening Lecture" of the School of Medicine of the University of Southern California was given on Thursday, October 15, at 11 a. m. in the auditorium (main floor), Los Angeles County Hospital. The lecture was given by Dr. Loren Roscoe Chandler, Dean of the School of Medicine, Stanford University. A large audience of attending staff and other physicians was present.

Ring Robs Blind: United States Seizes Thirty Fake Eye Surgeons.—Universal News Service prints the following:

"Dealing a smashing blow at what they described as 'the most vicious band of racketeers in the nation,' postal inspectors tonight had seized thirty fake eye surgeons and wrecked a five million dollar a year bogus medical business.

"The arrests, made quietly throughout the country over a period of more than a month, climaxed an investigation extending over a year. The names of those seized have been withheld by postal officials."

Nation-Wide Dope Drive. — The Treasury recently threw 2,500 narcotic agents and law enforcement officers into a nation-wide drive against narcotics and illicit liquor.

In scattered cities throughout the country Treasury agents were ordered to make a series of sudden raids in an effort to round up a large number of suspected law breakers.

Officials said several hundred arrests were expected to result from the raids which were ordered by Harold N. Graves, assistant to Secretary Morgenthau and coördinator for the Treasury's various law-enforcement agencies.

The activities were being centered in the fifty or more cities where various Treasury enforcement agencies maintain offices.

Ohio State Department of Health Exhibit at State Fair.—With the most diversified exhibit it has ever had at a State Fair and one of the best displays in its history, the State Department of Health, for all its vital importance to the people of Ohio and the magnitude and diversity of its educational program, found itself crowded into less space than it has had for years, in an obscure building off the main line of traffic. Nevertheless, a system of direction markers distributed over the Fair grounds led large crowds to its doors, and those in charge were busy from early morning until late at night presenting the various angles of public health work and administration to those who pay for it, answering their questions and demonstrating some of the most important features for their visual education.

Two outstanding features held greatest interest for the greatest number of visitors. One of these was "Contacts," a moving-picture "talkie" which demonstrated the course of tuberculosis from the contact infection through all the stages of diagnosis and treatment. It was the heart of an exhibit by the Bureau of Tuberculosis, of which Dr. W. J. Smith is chief. The film was loaned by the Franklin County Sanatorium.

The other was the demonstration of mine-sealing operations in the Ohio coal fields, under direction of Major C. S. Slade of the Division of Sanitary Engineering, whose artistry and mechanical genius made the exhibit possible. . . .

All the other divisions and most of the bureaus had individual exhibits, including Industrial Hygiene and Occupational Diseases, Child Hygiene, Dental Hygiene, Hospitals, Communicable Diseases, Venereal Diseases, Public Health Nursing, Health Organization and Education, Vital Statistics, Rural Sanitation, Sanitary Engineering, Laboratories, Administration and Publicity. Distribution of literature was through the nursing division, although several bureaus distributed considerable quantities of their special publications. Dr. Finley Van Orsdall, Chief, Division of Communicable Diseases, as for many years, had charge of the Red Cross first-aid service, assisted by Dr. P. L. Harris and Dr. C. C. Beal.

It was a great exhibit, deserving of a better location and larger space. What the Department really needs is a substantial and commodious building of its own.

American Board of Obstetrics and Gynecology.—The next written examinations and review of case histories of Group B applicants by the American Board of Obstetrics and Gynecology will be held in the various cities in the United States and Canada on Saturday, November 7, 1936, and on Saturday, March 6, 1937.

The next general examination for all candidates (Groups A and B) will be held in Atlantic City, New Jersey, on June 8 and 9, 1937.

Application blanks and booklets of information may be obtained from Dr. Paul Titus, Secretary, 1015, Highland Building, Pittsburgh (6), Pennsylvania. Applications for these examinations must be filed in the secretary's office not later than sixty days prior to the scheduled date of examination.

Dr. William Dock.—Dr. William Dock was appointed professor of pathology in the Stanford University School of Medicine on September 1. He received his B. S. from Washington University in 1920 and his M. D. from Rush Medical College in 1923. He served as medical house officer at the Peter Bent Brigham Hospital in Boston, was a graduate student in Vienna, and then resident in medicine at the Stanford University Hospital, San Francisco.

Since 1926 Doctor Dock has been a member of the department of medicine of the Stanford University School of Medicine. He has been active in research in the field of pathology and physiology of the heart, kidneys, and diseases of the blood.

Associated with Doctor Dock will be Dr. David A. Wood, associate professor of pathology, and Drs. James B. McNaught and Alvin J. Cox, assistant professors of pathology.

California Mental Hospital Opened in Ventura.—The Los Angeles *Examiner* of October 13 printed the following news item:

FIRST UNIT OF NEW MENTAL HOSPITAL OPENED

Fifteen Hundred Guests Hear of New Ideal in Treatment of Mentally Ill at Camarillo

Amid serene Ventura County hills, in a cluster of airy and cheerful buildings, 1500 persons yesterday learned of the new ideal in the treatment of the mentally infirm.

The 1500 were guests at the formal opening of the first unit of the State's seventh mental hospital, the magnificent institution at Camarillo near Oxnard, sixty miles north of Los Angeles.

The present group of buildings, constructed at an expense of $1,380,000, is but the first part of an institution which will cost $7,000,000, and which will be built as rapidly as the Legislature appropriates funds. It will remove between 6000 and 10,000 men and women patients from the overcrowded mental hospitals now existing.

Governor Frank F. Merriam was the principal speaker yesterday. He was surrounded at the microphone by many other state officials, officers of the Ventura and Oxnard Chambers of Commerce and other organizations of that locality, and delegates from Los Angeles, including Health Officer George Parrish, representing Mayor Frank L. Shaw.

Also on the platform was Adolfo Camarillo, descendant of the famous ranching family after whom the institution is named, and Dr. Thomas W. Hagerty, superintendent of the hospital.

After the speeches, in which the institution was hailed as potentially the finest in the United States, George B. McDougall, State Architect, and Harry Lutgens, Director of State Institutions, aided in exhibiting the unit to the visitors.

A ranch of 1648 acres is provided for the hospital, for which $424,217 has been appropriated to date.

Present construction includes the men's unit, which also houses the administration offices temporarily, and the laundry, service plants, boiler rooms, and sewage-disposal plant. The handsome Spanish-type main building is only partially completed, and when finished will surround a seven-acre plaza.

The next unit to be built, the home for women, will be similar in construction.

One hundred and sixty patients already are receiving care in the hospital.

LETTERS

Concerning support of Army Medical Library.

MEDICAL LIBRARY ASSOCIATION
2 EAST 103RD STREET
NEW YORK, N. Y.

September 25, 1936.

To the Editor:—The Medical Library Association at its annual meeting, June 22, 1936, passed a resolution recommending the appropriation of adequate funds for the Army Medical Library and its *Index-Catalogue*, a copy of which is attached. In order to secure the widest possible attention in medical circles, this resolution is being distributed in four ways:

1. By sending it direct to the President of the United States, and other government officials concerned (in January, 1937).
2. By publication in medical journals.
3. By sending it to our own members, with the request that they urge the organization of which they are a part, as well as all other local medical associations and institutions not members of our Association, to adopt similar resolutions to be sent to their local members of Congress, requesting their support of these measures.
4. By sending it to the secretaries of national and state medical societies, with the request that they urge similar action by their organization.

If it is in any way possible, we beg that you will publish this resolution in your journal, urging your readers to request their congressmen, upon the convening of the new Congress in January, 1937, to support these measures.

What is needed is to bring home to congressmen the fact that the whole medical profession of the country does benefit by this great library and its *Index-Catalogue*, and does want it to have this material. Letters from individual doctors to their congressmen would also carry weight. We hope and believe that a really concerted effort by the entire medical body will help to secure the desired funds for the Army Medical Library.

Very truly yours,
MEDICAL LIBRARY ASSOCIATION.

* * *

The resolution of the national Medical Library Association, recommending the appropriation of adequate funds for the maintenance and growth of the Army Medical Library's book collection and *Index-Catalogue*, follows:

The Medical Library Association, comprising two hundred of the medical libraries of the United States and Canada, assembled in its thirty-eighth annual session in St. Paul, June 22, 1936, notes with pleasure and pride the appearance of Volume 1 of the Fourth Series of the *Index-Catalogue* of the Library of the Surgeon-General's Office, United States Army (Army Medical Library). The Association records with satisfaction the abbreviations and changes in composition in this new volume, effecting a saving of 20 per cent in space with accompanying reduction in cost.

After a delay of three years, during which no volumes of this *Catalogue* were printed, the appearance of this first volume of the fourth series gives renewed assurance of the continuation of this publication, which, together with the Army Medical Library, is considered the outstanding contribution which our country and its Government have made to medical knowledge; and

WHEREAS, The value and usefulness of the *Index-Catalogue* is dependent upon the completeness of the files of medical publications contained in the Library of the Surgeon-General's Office—a public, national, medical library, the greatest in the world, serving in its present form of administration with satisfaction the medical profession and the medical libraries of our country; and

WHEREAS, In recent years the annual appropriation of the Congress has been wholly inadequate to provide sufficient funds to acquire the current medical books and periodicals issued throughout the world, so that they might be available for use throughout the country and for inclusion in the *Index-Catalogue*; therefore be it

Resolved, That the Medical Library Association urges the Congress to appropriate annually to the Library of the Surgeon-General's Office an adequate sum for current medical books and periodicals and for the purchase of back publications lost during those recent years when the amount granted was grossly inadequate, thus depreciating the completeness and usefulness of the Library's collection; and an additional sufficient sum annually, for as many years as may be required, in order to make for the greatest possible completeness of the collection and its *Catalogue*; and be it further

Resolved, That a sum be appropriated annually to defray the cost of printing regularly each year not less than one volume of the *Index-Catalogue*; and be it further

Resolved, That a copy of these resolutions be spread upon the minutes of the annual meeting of this Association and sent to the President of the United States, the presiding officer of both houses of Congress, the Secretary of War, the Surgeon-General of the Army, and to the national, state, and other medical periodicals with a request for publication, and to the members of this Association, urging the organization of which they are a part and all other medical associations and institutions to adopt similar resolutions to be sent to their local members of Congress requesting their support of these measures.

Concerning legal justification for an abortion.

(Copy)

STATE OF CALIFORNIA
LEGAL DEPARTMENT

San Francisco,
October 19, 1936.

Dear Doctor*:—Under date of October 12, 1936, you state as follows:

> I am writing you for a little legal advice as a member of the ——— County Medical Society and the California Medical Association. The case is as follows:
>
> A woman is pregnant and wishes an abortion done upon the following grounds: She has a brother who is mentally defective and two cousins that are mentally defective on her mother's side. Her husband has a brother that is mentally defective and there are also cousins on this side of the family that are mentally defective. This woman gave birth to a dead baby, prematurely, some time between the seventh and ninth month—her first pregnancy. Her second pregnancy yielded a boy who appears to be healthy. The third pregnancy produced a boy who is decidedly mentally and physically defective. There is possibly some syphilis in the family history, but this patient herself shows no evidence of syphilis.
>
> Now the question is whether the approximate 65 or 75 per cent of possibility that this pregnancy might produce a defective is sufficient legal reason for producing an abortion. I am willing to do the abortion if it is legal to do so. But, of course, would not for one minute do such a thing unless I have legal justification.
>
> I have talked with several doctors who themselves feel that it would be right to do an abortion in this case. Please let me know if there is anything in the law or court decisions upon this subject—one way or the other.

In reply, please be advised that the question asked by you concerns a private right of your own and not a public one. It should, hence, be referred to private counsel. Under the law it is the privilege and duty of this office to officially advise only certain state officers, boards, commissions and the various district attorneys throughout the State.

I may, however, informally state to you that Section 274 of the Penal Code, as amended in 1935, provides as follows:

> Every person who provides, supplies, or administers to any woman, or procures any woman to take any medicine, drug, or substance, or uses or employs any instrument or other means whatever, with intent thereby to procure the miscarriage of such woman, unless the same is necessary to preserve her life, is punishable by imprisonment in the State prison not less than two nor more than five years.

You will note that the only exception made in the defined offense is that the abortion be "necessary to preserve her (the woman's) life."

The necessity it has been held justifies the act. (*State* vs. *Fitzporter*, 93 Mo. 390, 6 S. W. 223.)

In *State* vs. *Rudman*, 136 Atl. 817, the Supreme Judicial Court of Maine recently interpreted a statute similar to our own, as follows:

> It is well known that occasion arises where, in the exercise of proper surgical advice and care, it becomes neces-

---

* Name of physician addressed is omitted.

sary, in order to save the mother's life, to remove the unborn foetus. To such highly honorable and proper acts, in accord with the highest ethics of the medical profession, the dictates of humanity, and all legal precepts, the statute has, and can have, no application. But to the destruction of unborn life for reasons, whatever they may be, other than necessity to save the mother's life, the law is intended, we believe, to be an express and absolute prohibition.

Trusting this may be of some informal assistance, I am

Very truly yours,
U. S. WEBB, *Attorney-General.*
By LIONEL BROWNE, *Deputy.*

CC: Board of Medical Examiners,
State Annex Building,
San Francisco.

Concerning information on human genetics.

BUREAU OF HUMAN HEREDITY
115, GOWER STREET, LONDON, W. C. 1
ENGLAND

To the Editor: — My Council would be very much obliged if you would be good enough to insert the accompanying notice in your next issue; and either in two subsequent issues or in another two alternate issues.

The object of this Bureau is, in the first instance, to collect as complete a record as possible of current information on human genetics. The only practical method is by making our needs known widely through scientific and medical journals, and your courtesy in this matter would be greatly appreciated. As such a notice might easily be overlooked, some editors have suggested to us that repeat issues will be necessary.

Later on, when a considerable amount of material is already available, we should be glad to furnish you from time to time with notes on the more interesting and important material which may come in. I need hardly add that we are not proposing to put in insertions as paid advertisements as the existence of the Bureau is a matter of interest to all scientific and medical men concerned with man.

R. RUGGLES GATES, F. R. S., *Chairman.*

* * *

The object of the Bureau of Human Heredity, 115, Gower Street, London, W. C. 1, England, is collection on as wide a scale as possible of material dealing with human genetics. Later, the tasks of analysis of material and distribution of the information available will be added.

The Bureau is directed by a Council representing medical and scientific bodies in Great Britain. It is affiliated to the International Human Heredity Committee, which ensures coöperation in all areas where research is proceeding.

The Council would be grateful to receive all available material from institutions and individuals, furnishing well-authenticated data on the transmission of human traits whatever these may be. Pedigrees are particularly desired; twin studies and statistical researches are also relevant. As research workers and others who send in material may in some cases wish to retain the sole right of publication (or copyright), those who so desire are asked to accompany their material with a statement to that effect.

Material should be given with all available details in regard to source, diagnostic symptoms, and the name and address of the person or persons who vouch for accuracy. All such details will be regarded as strictly confidential.

Reprints of published work would be most acceptable. Further, many authors when publishing material may also have collected a number of pedigrees which they have been unable to reproduce in detail. It is the object of the Council that such records, by being included in the Clearing House, should not be lost.

Those wishing for a copy of the Standard International Pedigree Symbols may obtain one from the office.

Announcements in regard to the services undertaken by the Bureau will be published from time to time.

Concerning codification of Medical Practice Act.

Under the caption, "A New Legislative Problem: Possible Danger to California State Medical Practice Act," editorial comment was made in the October CALIFORNIA AND WESTERN MEDICINE (pages 305-307).

A copy of the issue was sent to statute reviser, Mr. Arthur McHenry, who has the codification in charge, and from him has been received the following interesting reply:

CALIFORNIA CODE COMMISSION
CREATED BY THE PROVISIONS OF CHAPTER 750
STATUTES 1929
OFFICE: 206 STATE CAPITOL, SACRAMENTO

Sacramento, California,
October 19, 1936.

George H. Kress, M. D.
Editor, California and Western Medicine
945 Roosevelt Building
727 West Seventh Street
Los Angeles, California

Dear Doctor Kress:

This is to thank you for sending us a copy of the October issue of CALIFORNIA AND WESTERN MEDICINE, containing an editorial discussing the tentative code revision of the State Medical Practice Act.

It was with interest that we read the editorial and comment concerning the work of the Code Commission. We realize that the Medical Practice Act is a complicated piece of legislation and that it is difficult at times to secure the exact meaning of its provisions without actively participating in its daily operation.

To secure this exact meaning is the objective of the California Code Commission, and we are quite anxious to coöperate with you and your associates who are experts in this field of legislation, to secure a draft of the code which will meet with your approval and not require litigation to establish the scope of its terms and the constitutionality of its operation.

We have found in respect to the drafting of other codes in the past that we were in accord in regard to many of the objections and criticisms that were received, and were able to adopt them in advance of the conferences, which thoroughly check the drafts, section by section. In this manner the points for discussion have usually been reduced to a material extent, the remaining issues clarified, and the conferences rendered more fruitful of concete results than might have been possible in the absence of a preliminary exchange of views.

As you are undoubtedly aware, the draft must have the approval of the representatives of your profession before it is submitted to the Legislature, and we will be glad to work with you towards this objective. It is our aim to submit this draft to a thorough and complete study, section by section, in order that the final result will produce a code that correctly and clearly states the existing law in a manner that is satisfactory to you.

A conference, or a series of conferences, may be held at any time and place that suits the convenience of the representatives of the medical profession, as we are preparing to devote as much time and study as is necessary to accomplish our objective in a manner that meets with their approval. We have written to Dr. Charles B. Pinkham, Secretary of the State Board of Medical Examiners, to this effect and undoubtedly we will be informed of your wishes in this regard.

Finally, we wish to assure you that we shall exercise the utmost care and effort to avoid any changes in the standards of education and licensure that will embarrass the enforcement of the Act and permit unlicensed persons under the present Medical Practice Act to practice as physicians and surgeons in California. We feel, as you do, that if this should happen, it would be a real blow to public health and the best interests of the medical profession, and we are just as anxious as you are to avoid such a calamity.

Very truly yours,
FRED B. WOOD,
Secretary.
By ARTHUR MCHENRY,
Statute Reviser.

SPECIAL ARTICLES

MEDICAL JURISPRUDENCE*

By HARTLEY F. PEART, ESQ.
San Francisco

The execution of a release by an injured person to the person whose negligence caused the injury, bars an action by the injured person against a physician for alleged negligent treatment of the injury by the physician. Two Superior Court decisions have been rendered recently in which this principle was adopted and used by the Superior Judges presiding in the cases.

In the first case the plaintiff was injured in an automobile accident and was treated by the physician. During the course of his treatment he made a settlement with the insurance carrier of the automobile by the operation of which he had been injured. He then brought his suit for alleged malpractice against his physician, and in answering the complaint the physician's attorneys pleaded that he had accepted a sum of money from, and executed a release to, the operator of the automobile which injured him. Plaintiff's counsel demurred to this defense, but after argument the demurrer was overruled, the Court stating:

> I am satisfied that the weight of the authority supports the view that a release by one injured by another's negligence of the negligent person from all causes of action and claims arising out of the injury prevents an action by him against a physician for negligent treatment of the injury. (Citing 50 A. L. R., page 1106, and note commencing at page 1108.)

In the second case, decided some months previously, the evidence showed that the plaintiff had executed a general release to a railway company for the sum of $50, in which she released the railway company from all consequences which might flow from the accident. Thereafter the plaintiff brought suit against the doctor who attended her for the injuries sustained by the accident. The attorneys for the physician moved for judgment on the ground that the settlement made by the plaintiff with the railway company prevented the plaintiff from recovering any judgment against her physician. In giving judgment for the physician the Judge said:

> One thing we have to bear in mind is that as a result of an injury through negligence there is only one cause of action. All these other elements may enhance the damages, or they may mitigate the damages, according to the circumstances of the particular case; but there is only one cause of action, whatever the consequences are. Those consequences, whatever they may be, as I say, merely enter into the damage that the person has suffered; and if a person satisfies that one cause of action, then it is satisfied. . . . Another thing that I want to point out is this: That the theory underlying this principle of law that we are applying here is very apparently this: It is one of the natural, proximate results of an injury that the injured person will consult a physician. That must be regarded as a proximate result of the accident. It follows also that it is another proximate result for the doctor to treat that injury; and it follows, further, that in connection with that treatment there is always the possibility of an erroneous diagnosis and an error in treatment. All those things, however, under the cases which have been cited—and which appear to be beyond question in their weight—all of those things are the natural, logical, and proximate results of the original injury; and that is the theory upon which this principle is based.

111 Sutter Street.

---

* Editor's Note: This department of CALIFORNIA AND WESTERN MEDICINE, containing copy submitted by Hartley F. Peart, Esq., has been established by the California Medical Association Council. Each issue will contain excerpts from and syllabi of recent decisions and analyses of legal points and procedures of interest to the profession. These will be compiled and edited by Mr. Hartley F. Peart, General Counsel of the Association.

CALIFORNIA STATE DEPARTMENT OF INDUSTRIAL RELATIONS*

Mr. President, and Ladies and Gentlemen comprising the California State Federation of Labor:

May I take this opportunity of thanking you for the invitation to address your convention regarding the activities and affairs of the California State Department of Industrial Relations, under whose administration, and through whose Divisions all of the labor laws of California are applied and enforced.

You will find this statement to be very brief and pertaining only to those very essential parts of the departmental work, wherein the working men and women of California are most vitally concerned.

INDUSTRIAL ACCIDENT COMMISSION

Under the Workmen's Compensation Insurance and Safety Act, the Industrial Accident Commission was instituted in 1911 for two purposes: one, to care for employees injured in employment; two, the prevention of injuries to the working people.

During the life of the Commission the population of California has increased from 4,200,000 to nearly 7,000,000 people, and in spite of the tremendous increase in population which carries with it a proportional increase in injuries to care for, and preventive measures to institute, the Commission has less employees today than it did thirteen years ago.

For the biennium commencing July 1, 1921, the Commission had an appropriation of $853,746 and for the biennium commencing July 1, 1935, $732,080.

In other words, in spite of an increased population proportionately increasing the work of the Commission, we have had our budget reduced more than $120,000, and the personnel by more than 20 per cent.

To show the increase in work, I would call your attention to the fact that in 1935 there were 262,955 injuries reported, as against 230,901 in 1934.

In 1923 the total premium intake of all insurance carriers dealing with compensation in this State was $13,961,000, and in 1935 for the same business the intake was more than $22,000,000—this shows a huge increase in the number of workers affected by the compensation laws.

Our Safety Department, which enforces all laws designed to insure the safety of employees while at work, now has twenty-nine employees where there were formerly fifty.

Amendments to the compensation law in the past fifteen years have tremendously increased the work of the Industrial Accident Commission, and owing to a decreased personnel caused by decreased budget, we now find ourselves in a position where, if we are to afford the working people of California the protection to which they are entitled under the Workmen's Compensation Law, we must have an increased budget for the purpose of increasing our staff of inspectors and enforcement officers.

IMMIGRATION AND HOUSING

The proper housing of working people, particularly in the agricultural and rural areas, is of particular importance and a tremendously big job.

California has more than seven thousand camps scattered all over the State in which workers are housed.

There are around two hundred thousand migratory agricultural workers in the State.

To inspect more than seven thousand camps and properly care for more than two hundred thousand people, we have four inspectors. It is silly to expect that four men can do all this work properly.

To enforce the State Housing Act there is one man working full time out of the Los Angeles office and one man part time out of the Sacramento office. Under these conditions proper enforcement is impossible. The lack of proper enforcement of the State Housing Act is costing the State of California thousands of dollars every year through loss in property value, due to faulty and poor construction of buildings. This loss exceeds by far the $42,000 which it cost the State to operate this Division last year.

---

* An address by T. A. Reardon, Director, presented to the California State Federation of Labor, Sacramento, September 14, 1936.

DIVISION OF INDUSTRIAL WELFARE

This Division, which is entrusted with the enforcement of the orders of the Industrial Welfare Commission covering wages, hours, and working conditions of women and minors in California, effects in adjustments a very large increase to the earnings of these workers; and by routine inspections of payrolls and investigations of all complaints received, improper working conditions are improved, and hours of labor kept within the legal maximum.

During the past year this Division dealt with 10,964 plant inspections, investigations, calls, and audits.

By reason of its activities through its wage and audit adjustments it brought to the workers in this State $216,634.36 in the last fiscal year.

Comparing this wage collection of $216,634.36 to the cost of this Division to the State of approximately $27,000, you will note that this Division has paid for itself more than eight times over.

Despite this splendid showing, this Division has had its budget tremendously decreased in the past years and, like every other Division, with a lowered personnel it has been forced to try to carry on a great deal of additional work necessitated by a tremendous increase in the working population of the State.

DIVISION OF LABOR STATISTICS AND LAW ENFORCEMENT

During the last fiscal year this Division handled 22,768 wage complaints, 2,789 other complaints, and made 941 prosecutions. This Division of our Department is the police agency of the many labor laws of the State and, as you know, this is a real job all by itself.

However, and in addition to the labor law enforcement, $526,871.78 in wages was collected for the workers of the State who otherwise would have been cheated out of that amount.

When you compare the total of $526,871.78 wages collected with $172,520 which this Division cost the State of California last year, you will note that in wage collections alone this Division has paid for itself more than three times over.

CONCLUSION

By reason of the Social Security and State and Federal legislation designed to advance the interests of the working people of the State and nation, a tremendous amount of additional work has been placed upon this Department and the divisions comprising it.

I think you will agree with me that in spite of reduced budgets and lowered personnel our records show that a great deal of work has been done. There is a great deal more work that should be done and we would be happy to do it.

However, under the present budget and limited personnel we are tremendously handicapped, and if the working people of this State want stricter and more enforcement of the laws designed for their protection, it will be necessary for the State Legislature to allocate more money to the Department of Industrial Relations for the purpose of obtaining the necessary employees to carry on the work.

While the Department operates under the direction of Governor Frank F. Merriam, yet, to carry out the foregoing recommendations, it is mandatory that the Legislature make the necessary appropriations.

SUMMARY OF MORTALITY FROM AUTOMOBILE ACCIDENTS

The United States Bureau of the Census announces that during the four weeks ending September 26, 1936, eighty-six large cities in the United States reported 666 deaths from automobile accidents. This number (666) compares with 635 deaths during the four weeks ending September 28, 1935. Most of these deaths were the result of accidents which occurred within the corporate limits of the city, although some accidents occurred outside of the city limits.

For comparison, the number of deaths due to automobile accidents within city limits is desirable. Such figures are available for the four-week period ending September 26, 1936, and for the corresponding four-week period of 1935 for all of the eighty-six cities, the four-week figure in 1936 being 475 as contrasted with 463 for the corresponding four weeks in 1935.

Considering by four-week periods since January, 1931, total deaths from automobile accidents, whether within the city limits or outside, the lowest total (482) appears for the four-week period ending March 14, 1936, and the highest (890) for the four-week period ending December 22, 1934.

For the 52-week periods, September 26, 1936, and September 28, 1935, the totals for the cities were, respectively, 8,468 and 8,884, which indicate a recent rate of 22.8 per 100,000 population as against an earlier rate of 23.8, or a decrease of 4 per cent in the rate during the year.

Two cities reported no deaths from automobile accidents for the last four weeks, and six cities reported no deaths from automobile accidents for the corresponding period of 1935.

For the last four-week period reports as to whether deaths occurred from automobile accidents within city limits or outside were received from all of the eighty-six cities reported. In these cities in this four-week period, the total number of deaths from automobile accidents was 666, but only 475 of these were due to accidents within city limits.

Summary of Mortality from Automobile Accidents

TWENTY-FIVE YEARS AGO†

EXCERPTS FROM OUR STATE MEDICAL JOURNAL

Vol. IX, No. 11, November, 1911*

From an article on "Geographic Influences in the Etiology of Skin Disease" by Ernest D. Chipman, M.D., San Francisco.

It has, of course, long been recognized that certain diseases become more readily acclimatized and thrive better in some parts of the world than in others. . . .

From an article on "The Toxemias of Pregnancy" by Leroy H. Briggs, M.D., Oakland.

The toxemias of pregnancy are of absorbing interest, not only to the obstetrician, but even more so to the internist, the ophthalmologist, and the pathologist. Our present day knowledge of the subject has been gained chiefly from the results of the research worker, interpreted and correlated by the clinician. While many problems still await solution, the advances made within the past decade have been great, and the following paper will attempt a brief survey of some of them. . . .

From an article on "Unusual Cases of Syphilitic Osteo-Periostitis" by René Bine, M.D., San Francisco, Case 1.

Vertebral syphilis is so unusual a condition as to render the presentation of this case of more than passing interest. In its advanced stages, because of the similarity of signs, it is often difficult to differentiate such a lesion from infectious, traumatic or tuberculous processes, and in the pre-Roentgen and ante-Wassermann days, I feel certain that numerous cases were overlooked. . . .

From an article on "The Differential Diagnosis of Labyrinthine Affections" by G. P. Wintermute, M.D., Oakland.

The characteristic symptoms of labyrinthine affections are impairment of hearing, tinnitus, vertigo, spontaneous mystagmus, disturbance of equilibrium, sometimes nausea, vomiting and vasomotor disturbances, and very rarely head nystagmus. These symptoms may be excited either by disease of the end organ—the labyrinth—or by disease involving the nerve tracts leading from the labyrinth to its cerebral centers; and the symptoms vary in so far as the process is irritative in its effects or destructive, regardless of whether the lesion is in the end organ or along the central tracts. . . .

From an article on "Clinic Use of Psychotherapy, Illustrated by Cases from Private Practice" by Carl Renz, M.D., San Francisco.

The purpose of this paper is to discuss briefly the nature of psychotherapy, to illustrate its use from personal clinical experience, and to give a hint of its value in the work of the general practitioner. I shall not, therefore, give any historical data nor dwell to any great extent upon its psychological aspect, although the latter is a sine qua non for the understanding of the phenomena. . . .

Discussion.—Dr. H. D'Arcy Power, San Francisco: Some twenty years ago when the work of Charcot was in full swing, I was living near one of his assistants, Doctor Andre, so had a pretty close view of hypnotism and saw a great many cases. I think as Doctor Renz said that there is absolutely no danger or any great difficulties connected with this work except to the physician. He is the one most in danger because where you have a sprinkling of successes in hypnotism there are ten failures to every

BOARD OF MEDICAL EXAMINERS OF THE STATE OF CALIFORNIA†

By C. B. Pinkham, M.D.
Secretary-Treasurer

BOARD PROCEEDINGS

The annual meeting of the Board of Medical Examiners will open in the State Capitol, Sacramento, Monday, October 19.

Approximately seventy-one applicants are expected to report for written examination.

Legal hearings will commence Tuesday, October 20, at 10 a. m., the calendar showing the following licentiates have been called before the Board under Section 14 of the Medical Practice Act to show cause why their licenses should not be revoked for various derelictions:

Isaac S. Clark of Long Beach, alleged narcotic addiction.

John E. Cummings, Los Angeles, alleged illegal operation, continued from July meeting.

Hugo Foss, Los Angeles, narcotic conviction.

Henry L. Gardner, San Francisco, aiding and abetting, continued from July meeting.

Oscar Charles Long, Brawley, federal narcotic conviction.

George W. O'Donnell, San Francisco, alleged illegal operation.

Frank J. Parizek, Los Angeles, narcotic dereliction.

Francis W. Steddom, Los Angeles, narcotic dereliction.

Samuel Twain, Berkeley, narcotic conviction.

Wade H. Walker, Long Beach, narcotic conviction.

George E. Watts, Los Angeles, alleged illegal operation.

Thomas D. Wyatt, Redding, alleged illegal operation.

George H. Wymann, San Quentin Prison, convicted for illegal operation.

"Sensational charges of attempts of intimidating prosecution witnesses yesterday interrupted the trial of four physicians, six business men, and four women in Superior Judge Crum's court on charges of violating the state illegal operation laws. As a result Judge Crum ordered the trial halted temporarily for a special hearing this morning. . . . In presenting the charges to the court, Deputy District Attorney Ferguson and John J. McMahon, San Francisco prosecutor assisting at the trial, urged Judge Crum to order William Byrne, former investigator for the State Medical Board, and R. L. Rankin, both of whom are defendants, placed in custody for the remainder of the trial. . . . Dr. W. Norman Powers, a defendant, who recently pleaded guilty to the conspiracy charge . . . according to Ferguson, charges that his wife in Seattle recently received a long-distance telephone call in which she was told to stop her husband from appearing as a prosecution witness or he would suffer 'dire consequences.' The prosecution also charges that because of threats to Bernice Tieman, another witness in San Francisco, the woman apparently has fled and cannot be found. Others assertedly approached are Paul de Gaston and Mrs. Clara (Laura) Miner, residing in San Diego. It is charged that the defendants operated a million-dollar illegal operation ring, extending from Seattle to San Diego. So complete was the organization, the state contends, that physicians working for the ring were transferred from city to city at frequent intervals, so that they would not become too well known. . . ." (Los Angeles *Times*, October 8, 1936.)

"Testimony was given by handsome Paul de Gaston, Hollywood actor, and 'star' state witness, who for three days has been unfolding asserted 'inside' workings of the powerful (coast-wide operations) ring. De Gaston, who, although not a licensed surgeon, has testified he performed forty illegal operations upon women patients in ten days for the ring, told jurors today that in Seattle an imposing parchment was framed on the wall of his office and

ELECTRICAL STETHOSCOPE

Amazing new instrument amplifies heart sounds . . . Isolates and accentuates murmurs . . . Makes diagnosis of heart conditions easier

Some years ago, the Bell Telephone Laboratories designed the hospital type Electrical Stethoscope — for use in the operating amphitheatre. Now these same Laboratories have developed a *portable* model: The Western Electric 3A.

It has proved a valuable aid in diagnosing heart ailments—being particularly helpful to doctors with impaired hearing—as it amplifies heart sounds up to 100 times the intensity obtained with an ordinary acoustical stethoscope.

Doctors find it invaluable in examining thick-chested patients and in detecting heart conditions in their early stages. The *filter circuit* isolates and accentuates murmurs — often so hard to detect. Price $116.00.

BOARD OF MEDICAL EXAMINERS

(Continued from Front Advertising Section, Page 27)

"After testifying for three days, giving details of the inner workings of the coast-wide illegal operation syndicate, Paul de Gaston . . . today will face the cross-examination of defense attorneys in Superior Judge Crum's court. De Gaston's testimony was used by Deputy District Attorney Ferguson and John McMahon, San Francisco prosecutor, in an effort to convict ten men and four women of a conspiracy to violate the state illegal operations law. Dr. W. Norman Powers, another defendant, already has pleaded guilty to the conspiracy charge and probably will be used as a witness against the defendants. During the trial William Byrne, former investigator for the State Medical Board, and Rankin were ordered placed in the county jail until the end of the trial after the prosecutors had made a showing that they had attempted to intimidate witnesses." (Los Angeles *Times*, October 13, 1936.)

"Fifteen men and women yesterday, in Superior Court, heard themselves accused of illegal surgery on a gigantic scale by the third member of their alleged tri-state ring to turn state's evidence. Dr. W. Norman Powers in Seattle yesterday declared that in the summer of 1935 he joined the purported Pacific Coast operations monopoly at a salary of $1,000 per week. There followed a tour of California, Oregon, and Washington, in which he witnessed the 'technique' of a large number of the organization's practitioners before he opened a clinic in Seattle. Like Paul de Gaston and Marvin Raithel, who already had testified, Doctor Powers was indicted following the coast-wide raid of last June. He is listed as one of the defendants in the present trial, although he pleaded guilty to a conspiracy count while the jury was being chosen. Doctor Powers began his story by naming R. L. Rankin, accused business genius of the alleged ring. He said he went with Rankin to Oakland, where he witnessed illegal oper-

RY-KRISP *for*
Common Constipation

The beaker at the left contains one dry Ry-Krisp wafer, crumbled. At the right is the same quantity of saturated Ry-Krisp—showing what happens when the liquids in the stomach come in contact with it. Each wafer absorbs five times its weight in water, producing bulk to stimulate peristaltic action.

RY-KRISP, DRY
RY-KRISP
RY-KRISP SATURATED

BECAUSE it is a tempting, highly palatable food which patients are glad to eat regularly, many physicians find Ry-Krisp ideal as a natural corrective for common constipation due to insufficient bulk.

Made simply of whole rye, salt and water—double-baked to tempting, brittle crispness—Ry-Krisp has a high percentage of bran, high pentosan and crude fiber content—all of which encourage normal bowel action. Moreover, its low water content (only 6.8%) and porous structure permit each wafer to absorb five times its own weight in water. This produces needed bulk to stimulate natural peristaltic action.

The very fact that Ry-Krisp is such a pleasant alternate for crackers, toast or bread—at breakfast, lunch or dinner—is assurance of satisfactory results in the diet. Your patients —both children and adults—are glad to eat these crisp, whole rye wafers regularly.

-ations performed by Dr. James Beggs, one of the defendants. Doctor Powers continued that he and Rankin came to Los Angeles from San Francisco. Here, he said, he found headquarters of the purported syndicate and watched operations by Dr. George E. Watts, accused medical head of the organization. At the Hollywood Clinic, Doctor Powers said, he watched operations by other surgeons allegedly connected with the ring. Then followed a similar visit to Long Beach, where he said he met Grace Moore, another defendant. Then, he said, he returned to Seattle. He testified his salary began July 19, 1935, and ended in May, 1936. Doctor Powers said that he was soon sent back to Long Beach, where he performed from fifteen to twenty operations monthly for seven months. One day, he said, Rankin came into the Clinic with William Byrne, former investigator for the California State Medical Board, who is one of the defendants. 'Mr. Rankin introduced Mr. Byrne as the official who could guarantee protection from the law,' Doctor Powers said. . . . The prosecution placed Raithel, former San Jose druggist, on the stand in the morning session to link a number of the defendants with alleged overt acts. He testified he was employed at $300 per month to solicit cases for the clinics from druggists. He had conversations . . . in that connection, he said, with Defendants Rankin, Violette Pelligrini, Dr. Jesse C. Ross, J. O. Shinn, John Creeth, J. C. Perry, and Doctor Beggs. . . ." (Los Angeles *Examiner,* October 14, 1936.)

"The alleged gigantic tri-state illegal operations ring used a 'confusion' plan in all illegal operations, in a designed plan to make prosecution of doctors performing illegal operations virtually impossible, Dr. W. Norman Powers told Superior Judge Arthur Crum and the jury, while being cross-examined as a star witness for the prosecution at the trial of alleged members of the ring. Doctor

BOARD OF MEDICAL EXAMINERS

(Continued from Page 39)

Powers said three doctors had to be in the room. Each was to be busy in some way in order to confuse the woman patient and make it impossible in case of subsequent trouble with the authorities for her to be positive in identifying which one performed the operation. Led on by Deputy District Attorney Vernon L. Ferguson, Doctor Powers told how this plan was used when an operation was performed on a nineteen-year-old Long Beach girl. Three physicians were in the room when she was placed on the operating table—Dr. Harry L. Huston, Dr. James Beggs and himself, Doctor Powers testified. . . . After the operation on the Long Beach girl, Doctor Powers declared, she became seriously ill and was sent to the General Hospital. . . . Doctor Powers said that Rankin offered the girl's mother $100 to keep quiet. . . ." (Los Angeles *Evening Herald-Express*, October 14, 1936.)

"Josephine Follett, receptionist for Dr. Jesse Ross, one of the defendants, yesterday described how the ring's Hollywood branch functioned. She testified that William Byrne, former State Medical Board Investigator and a defendant, was a frequent visitor at the clinic. 'All our patients were women,' she testified, 'and all the operations were abortion cases.' During the recess Judge Arthur Crum denied a request to release R. L. Rankin and Byrne on bail. The judge ordered them jailed for asserted attempts to tamper with witnesses. (United Press dispatch, dated Los Angeles, October 16, and printed in the San Francisco *News*, October 16, 1936.)

"Dr. T. C. O'Connor, Medical Director of Bret Harte Sanatorium at Murphys, today submitted his resignation to the San Joaquin County Board of Supervisors. Doctor O'Connor's action was closely followed by the resignation of four key members of his staff. . . . (Stockton *Record*, September 28, 1936.)

"Christie Jerian, healer . . . charged with violation of the State Medical Practice Act, in the alleged use of the prefix 'Dr.,' changed his plea to guilty of a technical violation of the law and was given a suspended sentence of $500 fine or one hundred days in jail. . . ." (Long Beach *Sun*, September 18, 1936.)

For Acidity and Allied Conditions, we suggest
ADAMS SPRINGS MINERAL WATER

● MANY physicians recommend the water in conjunction with the treatment of stomach, liver and kidney trouble.

ADAMS MINERAL SPRINGS is one of the seven known iron and maganese bi-carbonate springs in the world, and the only one in Western America.

It is not a cure-all, but it overcomes acid excesses in the body, and is a very mild but wonderfully effective eliminator. The bowels function without spasm, the kidney output is greatly increased, and there is *marked* drainage of bile from the gall bladder and liver.

There is also some constitutional upset for a few days, particularly in gall bladder cases. But this is soon over and your patient begins to show improvement and is now in condition to profit by any medication you may prescribe. If the case is an operative one, you have improved your patient and made of him a better risk.

We will be pleased to cooperate in any way whatever, and samples of water are yours for the asking.

ACIDOSIS *or* ALKALOSIS?

prescribe KARO

Acids galore are normally formed in the body and eliminated—carbonic, lactic, phosphoric and sulphuric. They are almost completely neutralized by base from cells, intercellular fluids and blood plasma. The body fluids thus maintain the normal faint alkalinity of pH 7.4.

But the defensive mechanisms of the body capable of preventing changes in reaction may be deranged in disease with consequent acidosis or alkalosis. Acidosis is associated with hyperpnea, diarrhea, dehydration, anoxemia, circulatory or renal insufficiency; alkalosis with excessive breathing, vomiting.

Treatment of acidosis is designed primarily to correct the underlying cause. In most types, fluids and fruit juices with Karo are forced every hour. In cases associated with ketosis (except where it is a disturbance in carbohydrate metabolism, as in diabetes mellitus) 20% dextrose is given intravenously at repeated intervals. In case of diabetes, insulin is given, by some authorities, simultaneously one unit for each gram of dextrose, until the condition is controlled.

Treatment of alkalosis depends upon the cause. The most common variety in children is that resulting from prolonged vomiting with loss of acid, salt and body water. No food is given by mouth except fluids with Karo, and saline intravenously. If alkalosis is the result of alkali administration in the presence of nephritis with poor kidney excretion of salts, large amounts of fluids with Karo will favor excess base elimination. Alkalosis from excess alkali administration is alleviated by forcing fluids with Karo.

In both acidosis and alkalosis, Karo is a carbohydrate of choice in the emergency of treatment. Karo consists of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor), not readily fermentable, rapidly absorbed and effectively utilized.

CAUSES OF ACIDOSIS

EXCESSIVE ACID FORMATION	
Acid	*Disturbance*
Aceto-acetic B-hydroxybutyric	Starvation Cyclic vomiting Diabetes Ketogenic diet
Lactic	Asphyxia Intestinal intoxication Respiratory failure Shock Burns
DEFECTIVE ELIMINATION	
Metabolite	*Disease*
Phosphate	Nephritis
Carbonic acid	Emphysema Respiratory obstruction Myocardial failure Narcosis

CAUSES OF ALKALOSIS

EXCESSIVE LOSS OF ACID	
CO 2	Hyperventilation Tetany Cerebral lesions (respiratory center) Hysteria Excessive crying
HC I	Vomiting Pyloric stenosis Intestinal obstruction
EXCESSIVE INTAKE OF ALKALI	
NaHCO 3	in Pyelitis in Nephritis

From Kugelmass' "Clinical Nutrition in Infancy and Childhood" — (Lippincott)

A BIOLOGICAL TEST

"Ciba" did not Instigate

Spa 'Stimulus'
Turf Officials Act, Revealing That Maeriel, Winner Last Wednesday, Was Drugged.
Coramine Found to Have Been Used—Owner Is Cleared of Any Suspicion.
RACING OFFICIALS ACT ON 2 TRAINERS TODAY
State Commission to Decide on Use of New Drug, Coramine, at Saratoga Track.

AMPULES
LIQUID

In August, Maeriel, a 30 to 1 colt, flashed far ahead of the favorites in a Saratoga race. Five days before, Maeriel had run a poor third; past performances had never labeled the horse a winning one. A special analysis of Maeriel's saliva, after its unexpected win, showed that it had been stimulated with Coramine, a Ciba product.

Ciba never intended Coramine for such use. The unique biological test does, however, forcefully portray the drug's stimulating power.

When the heart and respiratory system are failing—in accident cases, asphyxiation, poisoning "shock", pneumonia crises, etc.—the physician "calls for Coramine", the safe, dependable stimulant.

Carry a supply of Coramine in your bag, ready for emergencies . . . literature upon request.

one-half years, after diagnosing the illness she had contracted as diabetes. He is said to have informed the child's parents that use of insulin in treating her would prove fatal. . . . The baby went into a coma, was finally rushed to a hospital and was saved after heroic efforts of local physicians. . . ." (San Jose *News*, September 30, 1936.)

Globulin-Modified Antitoxins.—Just a year ago Lederle Laboratories announced these "Globulin-Modified" antitoxins with a five-page advertisement in the *Journal of the Americon Medical Association.* The claims then made stand unaltered by experience and are repeated here with additions.

Lederle at that time substituted the improved products for its old ones and laid aside its remaining stocks of the old type for use in case clinicians should hesitate to accept the new products and ask for the old. Not a single order ever came, not a single preference was ever voiced for the old thereafter; the Globulin-Modified antitoxins went smoothly into acceptance by Lederle's customers.

On the other hand, evidence multiples in their favor. Controlled comparisons by various hospitals where experience is sufficiently intensive and informal observations by individual clinicians all support the plain common sense of it—that proteins being a leading cause of serum disease, their modification and partial elimination reduces the incidence.

(Naturally the physician will remember that all these improved antitoxins are still protein solutions and will take the customary precautions to avoid or care for serum reactions.)

The passage of a year of widespread use without adverse challenge or incident confirms the confidence of the profession in Lederle's signal improvement in antitoxin therapy.

For literature, write to Lederle Laboratories, Inc., 30 Rockefeller Plaza, New York, N. Y.

Heinz Offers New Third Edition of Famous Nutritional Charts

Now you can get complete descriptive information about the nutritional values of foods—in one handy volume that's yours for the asking! Heinz book of Nutritional Charts—revised and brought up-to-date in a *third* edition—contains data covering the latest developments in vitamin and nutrition chemistry!

Packed within its 32 large-size pages is the cream of scientific research on human nutritional requirements. Outstanding bulletins, government and state bureau circulars, special review articles, and original contributions have been condensed for your convenience. Every authoritative source has been utilized to make the *new* Heinz Nutritional Charts better than ever!

At your fingertips are the latest facts about the chemical and biological properties of vitamins and minerals. Outlined in easily accessible form is reliable information on food allergy; so-called food poisoning; food fads; alkaline and acidic effect; and the toxicological aspects of diet. Here, in effect, is a convenient source of accurate information useful in prescribing diets for children, the sick and convalescent, that would take you days to look up elsewhere!

Write for your free copy of the Heinz Nutritional Charts now! See for yourself what a wealth of valuable material this handy new edition contains. There's no obligation. Just address your request to H. J. Heinz Co., Dept. CW311, Pittsburgh, Pa.

MORE AND MORE MEDICAL MEN throughout the United States are giving their exclusive recommendation to Heinz Strained Foods for infant and other soft diet cases. Their reason: only Heinz Strained Foods bear *both* the famous "57" Seal of Quality and the Seal of Acceptance of the American Medical Association's Council on Foods.

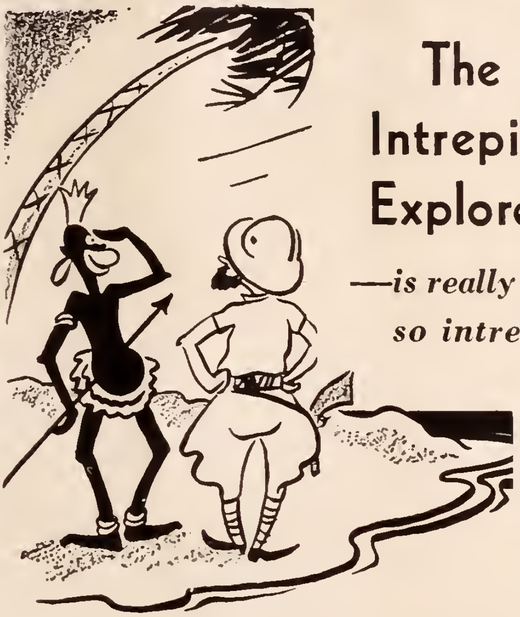
Not Advertised to Laity



The Intrepid Explorer

—is really not so intrepid

Unworthy of the name explorer would be the man who failed to arm himself with all available knowledge — however scant — about the region he planned to invade. Defiance of known dangers would be foolish.

The field of medical science is a well defined highway to those who have spent long years of study and practice in its exploration. New "lands" are yet to be discovered, but the approach must be by paths already blazed by the great names of science.

The dairy industry is our field of exploration. In places the paths of the milk industry and medicine lie close together, cross and mingle. We of Golden State recognize as our work that of bringing to the highest possible point the improvement, protection and value of milk products. Beyond that point—in the prescribing and promotion of milk therapy—we offer the public no guide. That is the field of medicine. That is your field.

Often, we are happy to say, our knowledge of the dairy business, and our trained technicians and research laboratories, are called upon by the medical leaders of California. These same facilities are available to you.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.

2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.

3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.

4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.

5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

ROBERT A. PEERS, M. D., *Medical Director*
Colfax, California

Not the Occasion for Compromise

WHEN THE new mother has passed through the first two stages of labor—her strength expended and her physical resources at an ebb—the outcome of her pregnancy must not be compromised. Observing every precaution, the experienced physician chooses his pituitary extract with care.

PITUITRIN, the Parke-Davis solution of posterior pituitary U. S. P. is the *original* commercial pituitary extract. The greater portion of the clinical data reported in the literature has been based on this preparation.

BECAUSE Pituitrin served to introduce pituitary extract to the medical profession, and because of its subsequent wide-spread use, the name is occasionally misapplied to other pituitary products. Be certain that Pituitrin (which is prepared only by Parke, Davis & Company) is supplied on all requisitions. Specify "Pituitrin, P. D. & Co."

PARKE, DAVIS & COMPANY

"Can chronic arthritis be treated with vaccine?"

MANY OF THE favorable reports of recent years on the treatment of chronic arthritis with vaccine have undoubtedly been over enthusiastic and uncritical. It remains a fact, however, that a number of competent clinicians and investigators find definite value in such preparations in selected cases; although opinion is divided both as to the type of case and the type of vaccine offering the most promise.

Sherwood's work with various types of vaccine intravenously is particularly encouraging, in-as-much as his results have averaged better than other series reported, while at the same time his cases have been well controlled.

For a review of the literature send the coupon.

Doctor Ely Joins Stearns Staff.—Frederick Stearns & Company announce the appointment of Lloyd L. Ely, M.D., as medical director.

The addition of Doctor Ely to the scientific staff of this well-known pharmaceutical house is a definite step in the research and professional expansion which Mr. Frederick S. Stearns has been fostering for the past several years.

Doctor Ely is a graduate of the State University of Iowa, and after his internship acquired some valuable clinical experience with Dr. Frank Smithies, famous Chicago internist and gastro-enterologist.

He has been much interested in diabetes and in the development of useful therapeutic agents. Doctor Ely has a wide acquaintance with clinical investigators, and his association with Frederick Stearns & Company is especially significant at this time, because of the intense research activities being carried on in the Stearns Scientific Laboratories.

AVAILABLE THROUGH ALL PHARMACIES

EMMENIN

The orally active, oestrogenic placental extract elaborated by Dr. J. B. Collip, Department of Biochemistry, McGill University.
(Canadian Medical Association Journal, February, 1930.)

IMPORTANT ANNOUNCEMENT . . .

By an improved technique developed in our laboratories, we have been able to render Emmenin entirely free from disagreeable taste and odor. This has been accomplished without loss of therapeutic activity, and the potency is ensured by carefully controlled biological assay.

DETAILS ON REQUEST

Emmenin is biologically assayed and standardized under direct control of the Department of Biochemistry, McGill University.

Secretary, Fred W. Didier, Wheatland.

VITAMINS . . .

as produced by Nature and protected by Science

THE vitamins A, B, D and G present in MALTINE WITH COD LIVER OIL are derived solely from natural sources. Throughout the entire Maltine process, care is taken to preserve the form and potency of these most essential factors. In the concentration and emulsification of MALTINE WITH COD LIVER OIL, for example, instead of the process being conducted under atmospheric conditions, the entire procedure takes place under vacuum at relatively low temperature, thus minimizing the possibility of oxidative and thermal effects shown by science to be so destructive to vitamins.

For 61 years, physicians have relied on MALTINE WITH COD LIVER OIL and prescribed it for their patients. Many are interested in knowing that tests with animals indicate that the vitamin A value of cod liver oil is enhanced *twofold* when emulsified in Maltine, as in MALTINE WITH COD LIVER OIL. The Maltine Company, 60 Hudson Street, New York City.

Belmont, California

Tell your patients, Doctor . . .

that

Ralston cooks in 5 minutes

Because so many mothers insist on using easy-to-prepare cereals, it's important that you remind them that Ralston cooks in 5 minutes. And of course, it's even more important to you and to your patients to know that Ralston is . . .

- **A WHOLE WHEAT CEREAL...** with only the coarsest bran removed ... providing an abundance of the body-building, energy-producing elements that come from choice whole wheat.
- **DOUBLE-RICH IN VITAMIN B...** pure wheat germ is added to Ralston to make it 2½ times richer in vitamin B than natural whole wheat.
- **PALATABLE AND ECONOMICAL...** tastes so good that the whole family likes it—and each generous serving costs less than one cent.

The Hot Whole Wheat Cereal Enriched with Extra Vitamin B

Ralston
WHEAT CEREAL
WHOLE WHEAT

RALSTON PURINA COMPANY, Dept. CW, 1840 Checkerboard Square, St. Louis, Mo.

CO-OPERATE WITH YOUR ADVERTISERS

California and Western Medicine, the official publication of your Association, is made possible in part by reason of the coöperation of business firms and institutions who use advertising space. Their purpose is to direct attention to their products and services to present and future patrons.

Members and readers are urged to give preference to and to patronize these advertisers. When ordering goods, mention California and Western Medicine.

This coöperation will please the advertiser, increase advertising income, and enable your Association to increase the value of this Journal to members and readers.

A SERVICE AGENCY—FOR READERS

The Journal of the California State Medical Association and the Coöperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital, or we will refer your request to the proper department of the A. M. A. for reply.

We invite and urge you to use this Service. It is absolutely *free* to every member of the California and Nevada Associations. The Coöperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in California and Western Medicine, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This A. M. A. Service Bureau will give you the information. Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to write direct to the Coöperative Medical Advertising Bureau, 535 N. Dearborn Street, Chicago, Illinois. California and Western Medicine and the A. M. A. Service Bureau desire to serve *you*.

THE CONTINUOUS COURSE IN

OPERATIVE SURGERY

Will Start January 5, 1937

DESIGNED FOR PHYSICIANS IN SAN FRANCISCO AND VICINITY

SUBJECTS INCLUDED:

Stomach and duodenum. Colon and rectum. Gall-bladder and bile ducts. Small intestines.

METHOD OF STUDY:

All of the above topics will be considered in the same manner. The descriptive and surgical anatomy of the organ in question will first be gone over, in the form of lectures, demonstrations on the cadavers, and dissections by the students themselves. The pathology, diagnosis and treatment of each subject will then be briefly considered, and particular attention given to the latest and most approved methods. The principal operations will be described by the instructor and performed by the students themselves on cadavers and fresh human material. Only the best and most up-to-date technique will be included and the students will be required to practice the work until they have not only mastered the subject but have developed the proper amount of skill and speed.

TIME REQUIRED AND FEE:

The work will be given every Tuesday from 11 a.m. to 2:30 p.m. Those desiring to spend additional time may do so without extra charge. Students taking the course will have the privilege of witnessing operations, with demonstrations, on the living at various times during the week. The fee will be $15 per month.

Applicants must be graduates of schools approved by the State Board of Medical Examiners

For descriptive circular and further information inquire of

SAN FRANCISCO POLYCLINIC AND POSTGRADUATE COLLEGE

William E. Stevens, M. D., *President* Otto G. Freyermuth, M. D., *Secretary*

A. J. REMMEL, M. D., *Director of Operative Surgery* 1535 JACKSON ST., SAN FRANCISCO

New York Polyclinic Medical School and Hospital. A special program was presented on October 2 at the Polyclinic Hospital for the American Academy of Ophthalmology and Otolaryngology, and was well attended by doctors from many parts of the country.

The Polyclinic presented the following program for the Graduate Fortnight of the New York Academy of Medicine on October 19 and 26:

1. Traumatic Pudendal Hernia (lantern slides) by Dr. Harbert C. Chase. 2. Tissue Asphyxia and Shock by Dr. Frederick M. Allen. 3. Traumas in the Newborn as the Pediatrician Sees Them, by Dr. W. Morgan Hartshorn. 4. Prevention of Obstetric Traumas (moving pictures) by Dr. Everett M. Hawks. 5. Physical Therapy in Traumatic Conditions (demonstration and lentern slides) by Dr. Richard Kovacs. 6. Perforation of Cervical Esophagus (lantern slides) by Dr. H. B. Orton.

1. Traumas of the Nose and Face by Dr. Lee M. Hurd. 2. Recurrent Dislocation of Shoulder by Dr. Toufick Nicola. 3. Traumatic Lesions of Short Rotators of Shoulder (lantern slides and presentation of cases) by Dr. D. M. Bosworth. 4. Trauma and Optic Atrophy by Dr. Ervin Torok. 5. Trauma of Chest (lantern slides and moving pictures) by Dr. Pol N. Coryllos. 6. Recent Advances in Tissue Grafting (charts, photographs and moving pictures) by Dr. J. Eastman Sheehan. 7. Exhibition of Pathological Specimens by Dr. Aaron S. Price. Dr. E. L. Kellogg was chairman of the Program Committee.

At the October meeting of the Polyclinic Clinical Society there were notable contributions, namely: 1. The Insulin Treatment of Non-Diabetic Tuberculosis by Dr. James S. Edlin. The discussion was opened by Dr. George G. Ornstein and Dr. Frederick M. Allen. 2. B. Friedlander Infections by Dr. George Baehr of Mount Sinai Hospital. The discussion was opened by Dr. Gregory Schwartzman (by invitation) and Dr. Lee M. Hurd.

Employment is nature's physician and is essential to human happiness.—Galen.

COOK COUNTY GRADUATE SCHOOL OF MEDICINE

(In affiliation with Cook County Hospital)

Announces Continuous Courses

MEDICINE—Informal Course first of every week; Intensive Personal Courses.

SURGERY—General Course, One, Two, Three and Six Months; Intensive Course, Surgical Technique, every two weeks; Special Courses.

GYNECOLOGY—Three Months' Course; Intensive Two Weeks' Course, starting February 15, 1937.

OBSTETRICS—Informal Course; Intensive Two Weeks' Course, starting February 1, 1937.

FRACTURES AND TRAUMATIC SURGERY—Informal Practical Course; Intensive Ten-Day Course, starting February 15, 1937.

EAR, NOSE AND THROAT—Informal Course; Personal Courses; Intensive Two Weeks' Course, starting April 5, 1937.

OPHTHALMOLOGY—Intensive Two Weeks' Course, starting April 19, 1937.

UROLOGY—General Course, Two Months; Intensive Course, Two Weeks; Special Courses.

CYSTOSCOPY—Intensive Course every two weeks (attendance limited).

General, Intensive and Special Courses in all branches of Medicine and Surgery.

TEACHING FACULTY—ATTENDING STAFF OF COOK COUNTY HOSPITAL

Address: Registrar, 427 South Honore Street, Chicago, Ill.

WANTED—(a) YOUNG PHYSICIAN, PREFERABLY UNmarried, especially trained in surgery; general and industrial surgery including fracture work; $300, complete maintenance; California. (b) Physician qualified in clinical laboratory work including milk analysis and technical x-ray; woman physician eligible; west coast. (c) Young obstetrician; preference for man qualified in pediatrics; should be in early thirties; until established in specialty, would be required to do some general work and surgical assisting; $250-$300, plus percentage; California. (d) OALR specialist, group appointment; Texas. C-100. Medical Bureau (M. Burneice Larson, Director), Top Floor, Pittsfield Building, Chicago.

POSITION WANTED—REGISTERED NURSE AND REGistered x-ray technician with seven and one half years clinical laboratory experience, also four years office and surgical experience desires position in either doctor's office or institution. References furnished on request. Address, Box 1200, California and Western Medicine, 450 Sutter Street, San Francisco.

WANT TO PURCHASE USED FLUOROSCOPE, SHORT wave diathermy, microscope, galvanic current generator, otoscope-ophthalmoscope, obstetrical bag. Anyone having any of the above articles for sale please write giving description and price of same. Address, Box 1220, California and Western Medicine, 450 Sutter Street, San Francisco.

Till taught by pain
Men really know not what good water's worth.
If you had been in Turkey or in Spain,
Or with a famished boat's crew had your berth,
Or in the desert heard the camel's bell,
You'd wish yourself where truth is—in a well.
—Byron

BOOK REVIEWS

Lane Medical Lectures. Studies in Cardiovascular Regulation. G. V. Anrep, M. D., D. Sc., F. R. S., Professor of Physiology, Egyptian University, Cairo, Egypt. Stanford University Press. Vol. III, No. 3. Price, $1.25.

Anrep admits that these lectures do not give a full account of circulatory regulations. He has restricted himself to his personal experiences. He sought to describe things as he saw them. A large field of circulatory pathology is covered in these five lectures dealing with: (1) Proprioceptive Mechanism of Cardiovascular Regulation; (2) Respiratory Regulation of the Heart Rate; (3) The Dynamics

NUTRI-AD
ARTHROPHYLL
(6)

A Nutritional Adjuvant

In a wide variety of cases involving Arthritis Deformans also Arthritic and Rheumatic disorders due to calcium deposition NUTRI-AD Arthrophyll (6) has accomplished favorable results to a degree heretofore unreported.

By making available prolific sources of organic phosphorus in a highly assimilable state it is apparent that this natural agency for increased calcium excretion has been provided. » » » » » » » »

This procedure together with inducing normal bowel elimination offers a likely solution to this stubborn and widely prevalent pathology. » » » » » » »

NUTRI-AD—ARTHROPHYLL(6) consists of the concentrates of green leafy vegetables so compounded and proportioned as to supply a maximum of phosphorus and a minimum of calcium through which the offending calcium deposits are disintegrated and excreted.

NUTRI-AD—ARTHROPHYLL(6) is available only in prescription form through the ethical medical profession. Literature gladly furnished on request.

BOOK REVIEWS

(Continued from Preceding Page)

of the Coronary Circulation; (4) Coronary Blood Flow; (5) Blood Flow Through Skeletal and Plain Muscles.

Many heard these lectures, some did not; all should be glad to have them available for careful study.

Keeping Your Child Normal. Bernard Sachs, M. D. Paul B. Hoeber, Inc. Price, $1.50.

Sachs in this 135-page book presents suggestions to parents, teachers, and physicians as guides to keeping a child normal. Fine suggestions they are, and the advice will be of definite value to every parent.

The chapter on the use and abuse of psycho-analysis is excellent and should serve in bringing a desired degree of common sense to parent and physician alike.

The text can be recommended to parents with every confidence that it will be helpful.

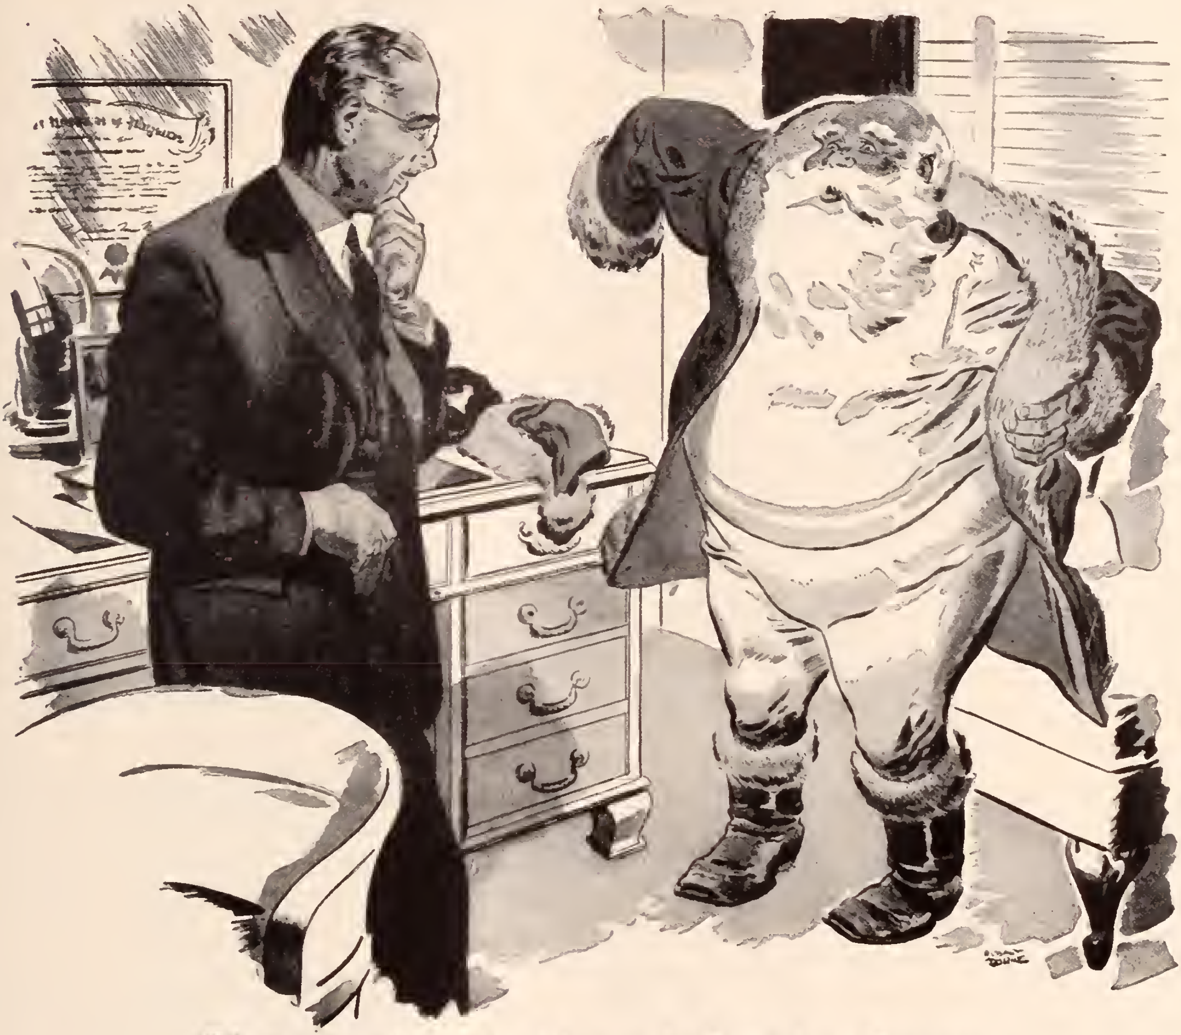
Bright's Disease and Arterial Hypertension. By Willard J. Stone, B. Sc., M. D., F. A. C. P., Clinical Professor of Medicine, School of Medicine, University of Southern California, Los Angeles; Attending Physician to the Pasadena Hospital, Pasadena, California. Pp. 352, with 31 illustrations. Philadelphia and London: W. B. Saunders Company, 1936. Cloth, $5 net.

Stone presents this monograph on the basis of personal cases over a period of twenty years, his personal studies, and the accepted literature. He has succeeded in placing before medical men a concise, practical discussion of the factors involved and has emphasized clinical features. He has contributed to a better understanding of Bright's disease and arterial hypertension.

One is impressed with the clarity of this presentation to such degree that there is no hesitancy in stating that every medical man will serve his patients more efficiently if he acquires the fundamentals of this text. The pathologic as well as the physiologic factors, their clinical

(Continued on Page 14)

One of a series of advertisements prepared and published by PARKE, DAVIS & CO. in behalf of the medical profession. This "See Your Doctor" campaign is running in a number of leading magazines.



The doctor looks at Santa Claus

WHAT'S THIS? Our old friend Santa in trouble?

Not exactly. He's just as bouncy and jolly as ever. His smile would light up a coal mine. But he is getting just a wee bit worried about his waistline. And well he might.

For obesity is dangerous. Superfluous weight makes every movement a greater tax on strength than that movement would be if weight were normal. It places an added burden on the fat person, a burden he carries wherever he goes, whenever he moves. And most of all, it places a serious and unfair strain on the heart by making it do extra work. *It has been estimated that putting on twenty pounds of fat adds about twelve miles of blood vessels and capillaries through which blood must be pumped.* And the heart, of course, must do the pumping.

You've often heard people say, "I must go on a diet". . . or . . ."I must go in for some strenuous exercise and work this fat off." But either course may be dangerous. Unwise dieting frequently substitutes, for the evil of obesity, the evil of undernourishment. Strenuous exercise obviously adds to the burden on an already overburdened heart.

There is only one sane thing for any overweight person to do. That is to see his doctor. Your doctor can determine whether obesity is caused by some fundamental physical disorder—such as glandular derangements—or whether it is the result of unwise eating combined with insufficient exercise.

Diet is a form of treatment; and it should *never* be prescribed by anyone but a physician. The doctor's knowledge is necessary in determining what foods, and how much, may be eaten—what diet will be safe and pleasant, yet effective, in removing unneeded, unsightly fat.

If *you* are overweight, or in doubt about what weight you should maintain, do something about it. But don't let well-meaning friends, or the fellow you met while on vacation, prescribe for you. See your doctor.

BOOK REVIEWS

(Continued from Page 12)

manifestations and therapy, are admirably correlated. The section on acute hemorrhagic nephritis is outstanding in its completeness. Some 140 autopsy abstracts are very instructive.

Here, then, is a text that deserves a place in the library of physicians in order that it may be frequently consulted, because it is dependable in every respect.

A Textbook of Obstetrics: By Edward A. Schumann, A. B., M. D., F. A. C. S., Professor of Obstetrics, School of Medicine, University of Pennsylvania; Surgeon-in-Chief, Kensington Hospital for Women; Gynecologist and Obstetrician to Philadelphia General and Memorial Hospitals; Obstetrician to Chestnut Hill Hospital; Consulting Gynecologist to Frankford, Jewish, Burlington County and Rush Hospitals. Pp. 780, with 581 illustrations on 497 figures. Philadelphia and London: W. B. Saunders Company. 1936. Cloth, $6.50 net.

This is a new text by a recognized authority. It is an excellent text, complete, well written, good illustrations, and specific in detail. Not much more need be said than to state that this monograph will be found to be very satisfying as a guide and should be favorably received by every physician engaged in obstetrical practice.

Surgical Clinics of North America. Issued serially, one number every other month. Volume 16, Number 3. New York Number, June, 1936. Pp. 277, with 79 illustrations. Per clinic year, February, 1936, to December, 1936. Philadelphia and London: W. B. Saunders Company. 1936. Paper, $12; cloth, $16 net.

A continuation of this well-known series, containing some interesting cases and several that may well have been eliminated. It is quite easy to cull out the clinic report that reveals lack of preparation and the casualness of the clinician. Ten of the subjects establish the value of this number. The symposium on the relief of pain is the outstanding feature.

International Clinics. Volume 3. Forty-Sixth Series. J. B. Lippincott Company.

An acceptable selection of papers, cases, and discussions constitute the worth of this third volume.

Principles of Chemistry. By Joseph H. Roe, Ph. D., George Washington University. C. V. Mosby Company. Price, $2.75.

This is an introductory text of inorganic, organic, and physiologic chemistry for nurses and students.

Fundamentals of Human Physiology. By J. J. R. McLeod, M. D., and R. J. Seymour, M. D. Fourth edition. C. V. Mosby Company. Price, $2.50.

Designed and written for elementary students and approved to that end.

An Historical Sketch of Los Angeles County, California: From the Spanish Occupancy, by the Founding of the Mission San Gabriel Archangel, September 8, 1771, to July 4, 1876. Prepared by Col. J. J. Warner, Judge Benjamin Hayes, and Dr. J. P. Widney. A reprint of the original edition published by Louis Lewin & Company, 14 Spring Street, Los Angeles, 1876. To which is added an introduction by Doctor Widney, July 4, 1936. Pp. 159, with portraits. Los Angeles: O. W. Smith. 1936.

Responding to the appeal of President Grant that each county in the United States should, in commemoration of the first century of the republic about to close, gather and publish the annals of its geographical section, the "Literary Committee of the Los Angeles Centennial Celebration" undertook to secure the historical survey so sensibly suggested; and with characteristic public-spiritedness, three of the pueblo-town's most distinguished citizens—Don Juan J. Warner, of Warner's Rancho fame; Judge Benjamin Hayes, presiding in early days by federal appointment over most of Southern California; and Dr. Joseph P. Widney, destined to found the first medical col-

for pernicious anemia . . .

1 cc. CONCENTRATED SOLUTION LIVER EXTRACT

Lederle

THE EXTENSIVE CLINICAL USE of this product during the past 18 months has demonstrated that pernicious anemia may be adequately treated by the use of this refined extract.

According to our interpretation, adequate treatment implies the treatment of other disease symptoms aside from those referable to the blood (number of red cells, hemoglobin, cell volume): the gastro-intestinal tract (glossitis, diarrhea, loss of appetite) and the nervous system (peripheral and central).

Extensive neurologic involvement frequently requires intensive therapy over a long period of time to bring about improvement. In the presence of marked nervous system changes a large amount of active substance is indicated, far in excess of that required to bring about a complete blood remission. Infection and advanced age usually add to the requirements for active material.

Clinical experience of the last four years has definitely shown that parenteral liver therapy is the most effective and most economical method of treating pernicious anemia.

1 cc. CONCENTRATED SOLUTION LIVER EXTRACT *Lederle* offers many advantages to the physician and the patient:

- Rapid improvement during relapse
- Maintenance with a relatively small number of injections per month
- A minimum of inconvenience to the patient with each injection
- Provides intensive therapy, still with little inconvenience, for those patients with extensive neurologic involvement

When The James H. Barry Company recently completed the tremendous task of moving its plant from 1122 Mission Street to its modern new building at 170 Van Ness Avenue South, it closed another chapter in the printing history of San Francisco, and began a new one—perhaps not so romantic, but certainly one with more sparkle and zest and a notable contribution to the industry.

Long known as the largest publication printers in Northern California, The James H. Barry Company in its new plant offers much greater facilities to publishers than ever before, both from the standpoint of craftsmanship and organization. Thousands of dollars worth of new machinery and equipment has been installed.

To buyers of direct advertising printing we offer a service unsurpassed in San Francisco. The great volume of this class of printing that is now being routed through our new plant is ample proof that our company is rapidly being recognized as a leader in this field.

The new plant of The James H. Barry Company is the consummation of an ideal. We have spared neither talent, time nor money to build a plant that would combine all the elements necessary for the production of first quality printing and the expediting of its manufacture and delivery.

We invite our customers and friends and all buyers of printed matter to visit us in our new establishment.

lege in the Southland—soon set to work energetically, finding it no easy task, despite the wealth of their own personal experiences and recollections, both to assemble and accurately check off such data as, fortunately, then was available from those pioneers still living, and to whip it into shape for the cannon-firing and oratorical fireworks in which the Angelenos were sure to indulge. That the result, from a strictly critical standpoint, was not 100 per cent perfection is not to be wondered at; but, considering that the self-sacrificing scribes had no forerunner in any similar local publication to guide or inspire them, it is not surprising that the modest booklet on straw paper and in ink strongly suggestive of shoe-blacking should, in a few years, become so scarce and unique that it long ago proved a costly item for Californiana collectors, making the enterprise of the republisher, himself long known to the Los Angeles book world, all more laudable. But two or three other booklets had previously appeared from Los Angeles presses and about the county, and it has generally been considered that Horace Bell's "Reminiscences of a Ranger" was the first pretentious work published (in 1881) in Los Angeles but now that the Smith reprint presents this so-called centennial history as a dignified volume of almost 160 pages, additional honors are due the veteran survivor of the trio of authors, the distinguished nonagenarian of the California medical profession, who was also the founder of the Los Angeles County Medical Association, for his enviable part in producing, after all, the first-known Los Angeles book!

For Even Anesthesia

The presence of nitrogen in nitrous oxide reduces the potency of the gas and narrows the already fine margin between anesthesia and asphyxia.

Ordinary nitrous oxide has to be only 95% pure to meet the U.S.P. specifications.

Stuart Hi-Pure is over 99% pure—so far as we know the *only* nitrous oxide of this purity manufactured in the United States. Longer nitrous oxide anesthesia can be obtained with a cylinder of Hi-Pure than with a cylinder of ordinary nitrous oxide.

May we mail you a booklet giving clinical data? Address 211 Bay Street, San Francisco.

SEATTLE, PORTLAND AND TACOMA

By agreement among themselves Colonel Warner, who had come to Southern California before the outbreak of the war with Mexico, and therefore knew better than many others the earliest events, wrote of the period from September 8, 1771, to January, 1847; while Judge Hayes, whose judicial peregrinations from Los Angeles to San Bernardino and San Diego made him familiar both with land and folk, told the happenings of the next two decades. Then Doctor Widney took up the narrative, closing his equally interesting story with the great day of the century, July 4, 1876. Not having yet come to his own, in his notable life work as pioneer educator and medical scientist, Doctor Widney has little to say of himself; but this reprint will ever be of exceptional value in the delightful foreword which he adds to pay his personal high tribute to the character and attainments of his literary colleagues. Colonel Warner having, as he says, "married among the Spanish and lived their life," no longer felt quite at home with his native English, and Judge Hayes was always modest and shy of appearing in print, although such an indefatigable researcher in history that the "Hayes Collection" has long been one of the glories of the Bancroft Library; with the result that both writers brought their manuscripts to the genial Doctor for such further elucidation as he might deem best! It is because of this incident, justifying, if ever, a wee bit of self-satisfaction, that what Doctor Widney has to say generously of his coworkers so redounds to the credit of all three concerned. "Colonel Warner," he testifies, "was a man of intelligence and of careful, observant mental habit; whether he kept a diary or not, I do not know, but every word written by him may be accepted as absolutely correct. I knew the man well, and it would take strong proof to make me question the accuracy of any statement he might make. Judge Hayes was a cultured gentleman, also of careful and methodical habits, who kept written records of men and events, and filed carefully much of the current printed matter. I attended as his physician in his last illness; and knowing the man intimately, I can unhesitatingly say that any statement made by him may be accepted as true, so far as human precaution can substantiate any historical statement." Well may the student of California history

A Modern Product

Of Proved Value in . . . the Endotoxic Infections

Edwenil, the polyvalent antibacterial agent, while comparatively new, has already been used so extensively that it has won the place of a leader in the treatment of the endotoxic infections such as the respiratory diseases, boils, measles, etc.

It is a stable, colloidal, protein-free (by the Biuret Test) solution for intramuscular injection.

Edwenil promptly raises resistance to the endotoxic infections but causes no detrimental reactions, either local or general. It can be used daily to advantage. Send for complete literature on

VITAMIN UNITS AND STANDARDS

● The past five years have brought agreement between biochemists of the various nations as to suitable units and standards of reference for most of the vitamins essential to man. The practice of expressing the vitamin potencies of foods and other biological materials in terms of *International Units* is, therefore, fast becoming universal.

Believing that these units and the standards upon which they are based would be of interest to our readers, they have been tabulated and defined below (1):

Vitamin A

The reference standard is a solution of pure beta-carotene in an inert oil, of such concentration that one gram of solution contains 300 micrograms (0.300 mg.) of beta-carotene. The International Unit, or I.U., of vitamin A is the vitamin A activity of 2 mg. of this standard solution, or 0.6 micrograms of beta-carotene.

Vitamin B1

The reference standard is the concentrate produced from rice polishings, by a specified adsorption method, in the Medical Laboratory of Batavia (Java). The International Unit for vitamin B_1 is the vitamin B_1 activity of 10 mg. of this standard adsorption product.

Vitamin C

The standard of reference for vitamin C is a specified sample of pure levo-cevitamic acid (levo-ascorbic acid). The International Unit for vitamin C is the vitamin C activity of 0.05 mg. of this standard.

Vitamin D

The reference standard for vitamin D is a solution of irradiated ergosterol, prepared under specified conditions at the National Institute for Medical Research (London). The International Unit for vitamin D is the vitamin D activity of 1.0 mg. of this standard solution.

These International Units for expressing vitamin contents have been specified in the most recent Pharmacopoeia of the United States (2) as well as by the Council on Pharmacy and Chemistry (3) and the Council on Foods of the American Medical Association (3), and provision has been made for distribution of the standards in this country (4).

These units have been used to express vitamin potencies in recent studies on canned foods, the results of which further emphasize the fact that these foods rank among the most important sources of the vitamins essential in human nutrition (5), (6), (7).

Surgery and pregnancy

place added strain on the diabetic

Resort to dietary measures alone is sufficient to keep many diabetic patients well-nourished, sugar-free and at work. When this is not practicable, or when infections, surgery, or pregnancy place added strain upon the patient, the use of Insulin is indicated. Furthermore, Insulin enables the patient to enjoy a wider variety of foods. This may aid in combating some of the complications.

Insulin Squibb is an aqueous solution of the active anti-diabetic principle obtained from pancreas. It is accurately assayed, uniformly potent, carefully purified, highly stable and remarkably free of pigmentary impurities and proteinous reaction-producing substances. Insulin Squibb of the usual strengths is supplied in 5-cc. and 10-cc. vials.

impose upon you by endeavoring to present all of the arguments, pro and con, but in a condensed way to give some views in defense of contract practice. . . .

From an article on "Salvarsan as a Nerve Tonic and Alterative" by Douglass W. Montgomery, M.D., San Francisco.

Since the fall of 1907 I have been, from time to time, consulted for cutaneous symptoms by a neurasthenic who first came on account of an erythematous eczema of the face and hands, that quickly cleared up under appropriate measures. Like many of his class, he became obsessed with the idea that he had syphilis, and the agitation in regard to salvarsan shook his ideas into acts, and he came to the city resolved to receive a treatment. . . .

From an article on "Proceedings of the Alameda County Medical Society" by A. A. Stafford, M.D., Alameda.

Treatment of Whooping Cough. When your Program Committee asked me to present a paper at this meeting I hesitated at selecting for my subject such a common, every-day theme as whooping-cough; but upon second thought, the very frequency with which the practitioner meets with the disease or some of its complications or sequelae, seemed to justify me in calling to your attention this malady, which, I fear, we all are apt to pass over hurriedly as not being worthy of our earnest attention. Thus we lose sight of the fact that we are dealing with a serious disease with very remote and lasting sequelae. . . .

From an article on "Bismuth-Iodin Paste in Discharging Sinuses" by L. D. Green, M.D., San Francisco.

In a case of discharging sinus following an operation for carcinoma of the breast, the surgical measures usually employed in such cases failed to close the sinus. After trying the various methods for two months, Beck's Bismuth Paste was used for three months, also without success. I then incorporated in the paste tincture of iodin, with the result that with three injections the sinus closed in ten days. I have since then used it in a number of other cases of discharging sinus with equally good results. . . .

BOARD OF MEDICAL EXAMINERS

(Continued from Text Page 520)

illicit surgery combine required patients to sign blank case record sheets before operations. In case operations resulted unfortunately, it is claimed by the prosecutors that the blanks were filled in with names of ailments which would make it appear that the surgery was attempted to save the life of the patient. Indelible pencil invariably was used, according to testimony of Inspector George Engler of the San Francisco Police Homicide Squad, because the writing thus showed uniformity, no matter how long a period elapsed between the operation and the development of adverse conditions. Mrs. Woods testified that she received one of the blanks, only to learn that later it had been filled in with a fictitious ailment after she had become seriously ill." (Los Angeles *Examiner*, October 20, 1936.)

"How she was taken from her home against her will, while suffering from blood poisoning as the result of an asserted illegal operation, and was placed in an apartment house at 1175 North Vermont Avenue for treatment, was described today by Mrs. Gladys Duckworth of Santa

Monica at the trial of thirteen men and women accused of being members of a coast-wide operations syndicate. While ill in the apartment house, she underwent another operation, which was performed without anesthetic on a kitchen table of the apartment, she declared. This operation, Mrs. Duckworth testified, was performed by Dr. H. L. Huston, with Bessie McCarthy in attendance as nurse. . . . The third operation, Mrs. Duckworth testified, was performed in August, 1935, by Dr. Valentine St. John, also a defendant in the case. Within five months of the third operation, she said blood poisoning became so critical that she was unconscious most of the time and it was then that, against her wishes, she was bundled into an automobile and taken to the apartment house. Later, she said, she was treated at a hospital in Hollywood, and still later taken to the General Hospital. While there, she said, John Creetch (Creeth), another defendant, called on her. When he left, she said, she found $100 under her pillow." (Los Angeles *Evening News,* October 20, 1936.)

"Bonds of three of the fourteen defendants in the wholesale illegal operations trial were raised from moderate sums to $5,000 each by Superior Judge Arthur Crum yesterday after a witness had told an amazing story of practices at the San Jose 'Clinic' of the asserted Pacific Coast ring. Nurse Viollette Pelligrini's bail was increased from $1,500 and the bonds of Dr. George E. Watts and Dr. Jesse C. Ross were raised from $2,500 each, after the astounding story of Miss Bernice Tieman, former San Jose nurse for the purported giant illicit surgery combine. In increasing the bonds, Judge Crum acted on his own motion, after Deputy District Attorney Vernon Ferguson had surprised the five defense lawyers with the announcement, 'The State rests.' Miss Tieman, San Francisco trained nurse, was produced by the prosecution in a surprise gesture. She had been sought for a month. The statement by Deputy District Attorney J. J. McMahon, San Francisco Special Prosecutor at the trial, that she had been frightened into hiding by threats caused Judge Crum two weeks ago to revoke the bonds of Rankin, business head of the asserted combine, and Byrne, former State Medical Board officer, and commit them to the county jail for the duration of the trial. 'Mr. Rankin told me after the raid on the clinics last June that they would get rid of me if I turned State's evidence,' Miss Tieman said. Miss Tieman is one of the thirty-one persons indicted at San Francisco in connection with the alleged ring's operations, including the group on trial here. . . ." (Los Angeles *Examiner,* October 21, 1936.)

"A pretty brunette nurse, 'prize mystery witness' for the State, testified today that she saw the bodies of two prematurely born babies destroyed at a clinic specializing in illegal operations. The witness was Miss Bernice Tieman, twenty-five, who was rushed here by plane from San Francisco." (Associated Press dispatch, dated Los Angeles, October 20, and printed in the San Francisco *Examiner,* October 21, 1936.)

"A nineteen-year-old blonde took the witness stand today at the trial of thirteen defendants accused of being members of a gigantic unlawful surgery syndicate, and told of an illegal operation she said was performed on her by Dr. George Watts, one of the defendants. . . . Deputy District Attorney Vernon Ferguson, handling the prosecution, said he was laying the foundation for his plan to prove that in the 'chain store' operation of the various clinics of the syndicate, large sums were frequently sent by telegram to R. L. Rankin, another defendant, and asserted 'business brains' of the organization. Ferguson said he would prove that many thousands of the million dollars he claims the syndicate made in 1935 were sent to Rankin by wire. Ferguson also said that later he would

THE COMMON COLD

It has been estimated by various authorities that over a billion dollars a year is lost to industry as a result of the common cold.

The increasing use of the so-called cold or mixed respiratory vaccine as a prophylaxis against colds by thousands of physicians on the Pacific Coast is evidence of its increasing popularity.

Hollister-Stier Mixed Respiratory Vaccine is prepared from over one hundred strains recently isolated from respiratory infections occurring on the Pacific Coast.

If you have not used Hollister-Stier Cold Vaccine, a trial may convince you that better results can be obtained.

introduce evidence to show that doctors with the firm sometimes, in order to make their business more lucrative, performed operations on women who needed none and simply were worried and fearful that they did need an operation." (Los Angeles *Herald-Express*, October 15, 1936.)

"Two women, a doctor and three Western Union messengers yesterday testified in Superior Judge Crum's court, adding new details to the charge against ten men and four women on trial accused of violating State illegal operation laws. The first woman called was Dorothy Woods. . . . She was followed on the stand by Josephine Follet, who testified she was a receptionist and nurse in a Hollywood clinic maintained by the syndicate. Mrs. Follet said that frequently while the office was in operation it was visited by William Byrne, at that time an investigator for the State Medical Board, who seemed to be friendly with the doctors who operated the clinic. In between the testimony of these witnesses, Deputy District Attorneys Ferguson and McMahon, the prosecutors, called three Western Union boys to testify to the delivery of money to R. L. Rankin, one of the defendants and accused of being the brains of the organization. The messengers testified that the money was taken to Rankin by them from various suburban clinics, assertedly operated by the Syndicate. Another witness called was Dr. Roy Buffum, Los Angeles physician. Doctor Buffum testified that in 1935 he was at liberty on probation for violation of the Medical Practice Act and that at that time he was approached by Rankin, who sought to induce him to join the Syndicate and assist them in opening another illegal operations clinic. Doctor Buffum testified that he refused the offer, despite the fact that, on a later visit, Rankin was accompanied by Byrne, who he said offered immunity from prosecution." (Los Angeles *Times*, October 16, 1936.)

"'Join or else' methods employed by members of the Pacific Coast illegal operations ring, today had been recounted to a jury by one who joined—and paid $1,000 monthly for the privilege. She was Mrs. Laura Miner, confessed operator of an operation clinic in San Diego, who testified yesterday for the prosecution against thirteen asserted members of the ring now on trial. . . . Mrs. Miner declared that a year ago William Byrne, one-time investigator for the State Medical Board and one of the defendants, approached her and said that unless she joined the Syndicate, he would cause her arrest. . . . Her connection with the syndicate was halted last June 4, she said, when Byrne warned her via telephone that 'trouble was brewing.' Another witness yesterday was Dr. Charles B. Pinkham, for twenty-three years secretary of the State

Medical Board. He testified that in 1934 R. L. Rankin, a defendant, who was said to be the 'brains' of the ring, boasted to him the law was powerless to prosecute the ring successfully. . . ." (Los Angeles *Evening News*, October 15, 1936.)

"An alleged $60 illegal operation that turned out wrong and cost R. L. Rankin, head of the Medical Acceptance Corporation, and alleged 'business brains' of a gigantic tri-state unlawful surgery ring, $310 to settle, was described by a Long Beach lawyer in Superior Court today. . . ." (Los Angeles *Herald-Express*, October 16, 1936.)

"Witnesses sufficient to continue another two weeks the trial of fourteen defendants in the tri-state illegal operations case, were listed yesterday by prosecution and defense attorneys, as the sensational hearing went into its fourth week in Superior Judge Arthur Crum's court. Deputy District Attorneys Vernon Ferguson of Los Angeles and John J. McMahon of San Francisco said the prosecution would not rest until next Thursday or Friday. . . . The State claims Rankin and Watts, with the official connivance of Byrne, set up large illegal operations mills in Los Angeles, the headquarters, and at San Diego, Long Beach, Hollywood, San Francisco, Oakland, San Jose, Portland, and Seattle. 'In the first year, 1934, the syndicate grossed $800,000,' McMahon charged. 'The income was larger in 1935 and was grossing even larger for 1936 before we launched our raids last summer." (Los Angeles *Examiner*, October 19, 1936.)

" 'The syndicate controls the District Attorney's office and the police and sheriff's offices in Los Angeles and is paying off the State Medical Board.' That is what prospective members of the coast-wide illegal operations ring were told when invited to join the operation monopoly, it had been testified today at the trial of thirteen alleged members of the ring. Dr. H. N. Tatem (licensed chiropractor), physician, was the State's witness who so testified yesterday in a dramatic session of the trial, today in its third week. . . . " (Los Angeles *Evening News*, October 17, 1936.)

"Prepared to close the prosecution's case against ten men and four women charged with violating the State illegal operations laws, V. L. Ferguson, Deputy District Attorney, and John J. McMahon, San Francisco Prosecutor, today will call additional witnesses in Superior Judge Crum's court. . . . Meanwhile the battery of defense counsel, Leonard Wilson, Otto Emme, David A. L'Esperance, Clarence W. Morris, and B. R. Rountree, announced they are prepared to open the defense of their clients at once and disprove the charges made by the prosecution." (Los Angeles *Times*, October 19, 1936.)

"Eleven of thirteen defendants were convicted on various counts and two were acquitted at the conclusion late yesterday of the month-long trial of nine men and four women on charges of conducting a gigantic Pacific Coast illegal surgery syndicate. Reading of the 117 separate verdicts required more than an hour and a half in the courtroom of Superior Judge Arthur Crum. Receiving the heaviest weight of the jury's judgment, convicted on five of the nine counts, were R. L. Rankin, asserted business head of the tri-state combine and organizer of its finance company, the Medical Acceptance Corporation; William A. Byrne, the ring's 'trouble shooter,' while he served as special officer for the State Medical Board; J. O. Shinn, Medical Acceptance Corporation executive; Drs. George E. Watts, Chief Surgeon, Jesse Ross, and James Beggs; Grace Moore and Lillian Wilson, nurses and office assistants. Viollette Pelligrini, nurse, was con-

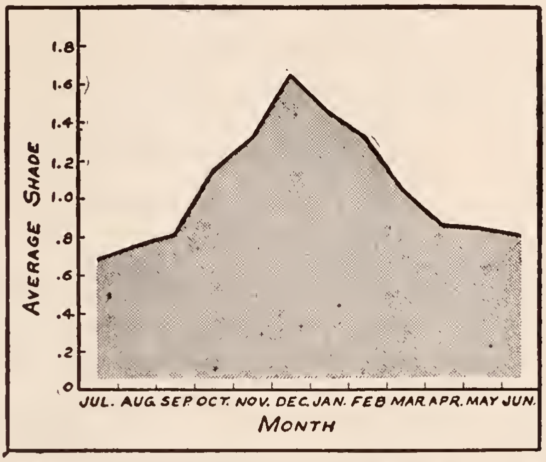
WEATHER FORECAST—
HEAVY SMOKEFALL

SMOKE exerts a definite influence on the weather at this season by reducing the amount of sunlight. Beginning in September there is a steady rise in atmospheric pollution until in December it becomes double that of midsummer, according to a recent report of a two-year study made by the U. S. Public Health Service in ten of the largest American cities, representing a population of millions. One of the most surprising findings was that there is no decrease in the dust content of the air either during or after a rain.



Average atmospheric pollution in 10 large American cities, 1931-1933. In many smaller communities, even worse conditions may prevail under any of the following combinations: (1) soft coal, (2) low inland wind velocity, (3) concentrated manufacturing activity, (4) no zoning regulations, (5) no smoke abatement ordinances.

Winter Sunlight an Unreliable Antiricketic

Atmospheric pollution is but one of many forces militating against the therapeutic effects of ultraviolet rays in winter. Others, to name only a few, are cloudiness, precipitation, and clothing. In winter, moreover, it is often impracticable to give sunbaths to infants during the very time they are most susceptible to rickets—the first six months of life.

Dependable the Year 'Round
OLEUM PERCOMORPHUM
Price Substantially Reduced Sept. 1, 1936!

The physician can dispel uncertainty in the treatment of rickets simply by prescribing a few drops of Oleum Percomorphum daily. The product has the advantage of having the same ratio of vitamins A to D as in cod liver oil,* with 100 times the potency. Each gram supplies not less than 60,000 vitamin A units and 8,500 D units (U.S.P.). This maximum vitamin potency in minimum bulk gives Oleum Percomorphum outstanding usefulness for young and premature infants. Constant bioassay and special processing of this antiricketic assure the stated vitamin potency and low percentage of fatty acids. Supplied in 10 and 50 c.c. bottles and 10-drop capsules in boxes of 25 and 100.

***U. S. P. minimum standard.**

BOARD OF MEDICAL EXAMINERS

(Continued from Page 24)

victed on three of the nine counts. Dr. Valentine St. John and John Creeth, the latter a Medical Acceptance Corporation official, were found guilty on two of the nine charges. Mrs. Jessie Radcliffe, who convinced the jury she was unfamiliar with the organization's purposes during her two weeks' employment in the Long Beach clinic, and J. C. Perry, who accepted a position with the Finance Company just before his arrest, were acquitted on all counts. . . ." (Los Angeles *Examiner,* October 25, 1936.)

"Superior Judge Arthur Crum today denied applications for new trials filed by eleven persons convicted in the illegal surgery ring trial and sentenced six of the eleven to San Quentin Prison for terms ranging from four to twenty-five years. The other five, including three women, were granted permission to file applications for probation and November 16 was set for the probation hearings and the pronouncing of sentences. All the defendants announced intention of appealing their convictions voted by a jury October 24. R. L. Rankin, who, the prosecution contends, was business head of the asserted coast-wide illegal operations organization; William A. Byrne, former special officer of the State Medical Board; Dr. George E. Watts, Dr. Jesse Ross, and Dr. James Beggs, each convicted on five counts, were sentenced to terms of from ten to twenty-five years each. Dr. Valentine St. John, convicted on two counts, was sentenced to a term of from four to ten years. Those permitted to file probation pleas were J. O. Shinn, John Creeth, Grace Moore, Lillian Wilson, and Viollette Pelligrini." (San Francisco *Chronicle,* November 3, 1936.)

"Dismissal of many of the thirty-one San Francisco indictments in the sensational coast-wide illegal surgery case, may result from a conference here today between Deputy District Attorneys Vernon Ferguson of Los Angeles and J. J. McMahon of San Francisco. McMahon, especially assigned to Los Angeles for the trial of thirteen defendants in the case, which resulted Saturday in the conviction of eleven and the acquittal of two, said all but three or four of the San Francisco accused may be freed of charges there. The dismissals would include the thirteen defendants in the Los Angeles hearing and alleged operators for the ring who turned State's evidence and

testified here, as well as a number whose connection with the organization was slight. . . ." (Los Angeles *Examiner,* October 26, 1936.)

"Making an eloquent plea for clemency, Dr. W. Norman Powers, Seattle physician, who recently pleaded guilty to conspiracy to violate the law in respect to illegal operations, yesterday was granted probation by Superior Judge Crum. . . . The probation calls for the serving of six months in the county jail as part of a three-year probationary period, during which he shall not practice medicine. Eight other counts against him were dismissed by the court on motion of Deputy District Attorney Ferguson. . . . The office of the District Attorney pointed out that Doctor Powers came to California at his own expense and pleaded as one of the minor defendants, saving the State considerable expense. Before granting the probation Judge Crum imposed the San Quentin sentence, which he suspended on condition of the jail sentence and the other stipulations. The doctor is privileged to leave the State after serving of the jail sentence. Application of Dr. Jesse C. Ross, convicted on October 24, last, in connection with the asserted illegal operation ring, for bail, pending his appeal, was denied yesterday by Judge Crum. Doctor Ross was sentenced to San Quentin on five counts after a jury returned a guilty verdict against him and ten others." (Los Angeles *Times,* November 10, 1936.)

"A woman witness called before the State Board of Medical Examiners in its trial of Dr. Thomas D. Wyatt of Redding on abortion charges today, faces legal action for refusal to testify. The woman is Mrs. Arsilia Briegel of McCloud, who declined to make any statement on ad-

vice of counsel. Immediately after the Wyatt hearing was adjourned (until the next meeting of the Board in Los Angeles in February), Lionel B. Browne, Deputy Attorney-General, who was prosecuting the case, said he would cite the record to the Superior Court in a move to force Mrs. Briegel to testify at the February meeting. . . ." (Sacramento *Union*, October 21, 1936.)

"Dr. Arthur M. Tweedie, arrested by police a week ago, yesterday was exonerated by the county grand jury with any connection with illegal surgical activities. The jury heard several witnesses before ordering Doctor Tweedie's release from bail. According to Deputy District Attorney Whichello, the physician was seized on suspicion as the result of the mention of his name in statements made by witnesses during the recent trial of several illegal operation 'specialists.' Testimony discloses that Doctor Tweedie had no connection with members of the illegal operations 'ring,' a number of whom were convicted and sentenced to prison, Whichello stated." (Los Angeles *Examiner*, November 11, 1936.)

"Dr. George W. O'Donnell, San Francisco physician, today had been granted a Writ of Review in Superior Court here, of the recent action taken by the State Board of Medical Examiners in revoking his license to practice." (Press dispatch, dated Sacramento, November 10, and printed in the Los Angeles *Examiner*, November 11, 1936.)

"A job almost any man would like to have went today to Dr. E. W. Laisne, Fresno. Laisne, an eye specialist (licensed optometrist), was appointed a member of the Directorate of the Elysium Nudist Colony cult here."

APPROVED CLINICAL PATHOLOGISTS

American Medical Association Essentials for An Approved Clinical Pathologist

An approved clinical pathologist should be a licensed graduate of medicine. He shall have specialized in clinical pathology, bacteriology, pathology, chemistry, and other allied subjects for at least three years, and he should be reasonably familiar with the manifestations of disease in the body. The director of a clinical laboratory shall be on full time or have definite hours of attendance, devoting the major part of his time to this specialty. A clinical laboratory is an institution organized for the practical application of the fundamental sciences by the use of specialized apparatus, equipment and methods, for the purpose of ascertaining the presence, nature, source, and progress of disease in the human body.

The following Clinical Pathologists directing private laboratories in California are approved by the Council on Medical Education and Hospitals of the American Medical Association:

Clinical Laboratory of Drs. W. V. Brem, A. H. Zeiler, Roy W. Hammack and G. D. Maner, 657 So. Westlake Avenue, Los Angeles, California.

Zera E. Bolin, M. D., 490 Post Street, San Francisco, California.

These laboratories use standard methods and are fully equipped to make all clinical examinations of recognized value in: Tissue Pathology, Bacteriology, Hematology, Serology, Bio-Chemistry, Kolmer Wassermanns, Kahn test, Medico-legal, Basal metabolism, Blood chemistry, Hormone Test for Pregnancy, Parasitology, Cardiology, Autogenous vaccines, etc.

Mailing containers sent on request. Special delivery postage insures prompt, accurate service.

(United Press dispatch, dated Alma, California, October 29, and printed in the Los Angeles *Illustrated Daily News,* October 30, 1936.)

"Eugene J. Rinaldo, fifty-one years of age, yesterday pleaded guilty to practicing medicine after his license was revoked and asked for probation, hearing on which was set for Monday by Municipal Judge Landrath. According to Deputy City Prosecutor Crandall, Rinaldo treated a patient for arthritis last July, charging a fee of $54. His license was revoked October 18, 1932, Albert Carter, State Medical Inspector declared." (Los Angeles *Times,* October 29, 1936.)

"Promising an exhaustive inquiry, Coroner T. B. W. Leland today reopened an inquest into the death of Mrs. Martha Kaufman, who died November 9, 1929, assertedly from a criminal operation, which was officially hushed. In court, as the session opened, were persons Attorney H. R. Hubbard described as 'prominent in the abortion business in San Francisco.' . . . Also waiting to testify were Mrs. Minerva Geddes Sissons and her sister, Mrs. W. L. Swindell, since arrested on charges of performing an abortion at 1115-1117 McAllister Street, where Mrs. Kaufman died; Dr. A. A. Berger, who signed the autopsy report of death by natural causes." (San Francisco *News,* October 29, 1936.)

"The jury trial of Frederick Mazain on four counts for practicing medicine without a license ended abruptly yesterday when Mazain withdrew his plea of not guilty to one of the charges and pleaded guilty, and had the other three dismissed by Justice Grandin H. Miller. The motion for the dismissal of the charges was made by Deputy District Attorney A. Andreuccetti, who was prosecuting Mazain. The complaint against Mazain was signed by Thomas P. Hunter, inspector of the State Medical Board.

BOARD OF MEDICAL EXAMINERS

(Continued from Preceding Page)

On the count to which he pleaded guilty Mazain was granted probation for two years and ordered to refrain from practicing medicine as a condition of probation." (San Jose *Mercury-Herald,* November 5, 1936.)

Albert Carter, Special Agent, Board of Medical Examiners, reported that Clifford Pickett, colored former janitor in the Venereal Disease Clinic of the Los Angeles City Health Department, was arrested on October 29 on a charge of violation of Section 17 of the Medical Practice Act, trial being set for November 24, and defendant confined to jail because of his inability to raise bail. According to the complaining witness, Pickett assertedly met his patients outside the clinic, induced them to visit his home in the evening and gave them hypodermic injections of salvarsan.

Recent report was filed with the Board of Medical Examiners that an individual giving the name of Ackerman, claiming to be from New York, was traveling about the State calling on doctors, offering to purchase samples of drugs and medicines which had been sent them by various drug houses. These, he said, he sent back to New York and sold them to druggists.

"William Byrne, at the time an enforcement officer of the California State Board of Medical Examiners, used his official power in 1935 to force Mrs. Laura Miner of San Diego to join the alleged coast-wide illegal surgery ring. R. L. Rankin, reputed business genius of the alleged tri-state organization, in November, 1934, boasted openly to an official of the Board that he intended to operate a large-scale illegal operations business, with such strong legal advice and protection that the law could not interfere. Two witnesses gave this sensational testimony yesterday in the trial of fourteen alleged members of the million-dollar syndicate—Mrs. Miner, herself, and Dr. Charles B. Pinkham, for twenty-three years secretary of the State Medical Board. After Doctor Pinkham had told of Rankin's alleged boasts, Mrs. Miner described how she paid $1,000 monthly tribute to the purported ring through the 'purchase' of the organization's San Diego Clinic, after Byrne had forced her to relinquish her own illegal operations business there. . . . Doctor Pinkham, questioned by Deputy District Attorney John J. McMahon of San Francisco, said Rankin called on him in San Francisco in November, 1934, with a protest against the complaints which had been received by the Board concerning the professional methods of Dr. George E. Watts, alleged medical chief of the ring, who at the time was moving his clinic from Oregon to California. 'Rankin told me,' Doctor Pinkham said, 'that he had learned the names of most of the large-scale illegal practitioners on the West Coast through his work as an income tax expert. I asked him if he contemplated establishing an illegal operations office in San Francisco. He said frankly that he was negotiating for one. I told him the State Medical Board existed to enforce the Medical Practice Act and that we knew cards were being distributed widely to advertise illegal operations and that we had heard solicitors were in the field seeking business from druggists and doctors. He replied that he and his associates had the best of legal advice and had no fear of successful prosecution by the Board. He added that he was purchasing a great many medical practices and was placing the offices under charge of young doctors, with instructions not to perform operations themselves, but to send cases to clinics maintained elsewhere.' The witness concluded that the law required doctors to list changes in their addresses, but that the reputed Rankin-Watts combine apparently changed surgeons and transferred licentiates from one to another so rapidly that the Board could never be sure of the location of any of them. Mrs. Miner identified for McMahon and Deputy District

(Continued in Back Advertising Section, Page 34)

"What's a bio-assay?"

Most patients at best have only a vague idea what a bio-assay is . . . know still less about the equipment, controls and skill necessary for running one properly. In selecting a vitamin product, you, the physician, of course look to the maker's ability and facilities for dependable bio-assaying. But patients can't be expected to do the same!

Moreover, it's known that vitamin products of deficient potency are offered for sale. To avoid the dangers such a situation holds, many physicians *write* all their prescriptions for Haliver Oil with Viosterol and specify *Abbott.*

This original research product has behind it every safeguard and manufacturing method which could contribute to certainty of quality. Each lot of oil is bio-assayed under conditions permitting greatest possible accuracy. Abbott maintains beginning-to-end control of production. That control is made doubly effective by Abbott's unique research and manufacturing experience accruing from the pioneer development of Haliver Oil Plain and with Viosterol.

Prescribe routinely for growing children, pregnant and lactating mothers, and all other patients who require additional Vitamins A and D. Available in soft, tasteless 3-min. capsules in boxes of 25, 50, 100 and 250. Also in 10-cc. and 50-cc. vials with special droppers. ABBOTT LABORATORIES.

EDITORIALS[†]

THE SEASON'S GREETINGS

The eve of a biennial legislative session in California, with potentialities of untoward public health legislation, makes good wishes for Christmas and New Year days particularly appropriate. If the year 1936, now coming to a close, meant to many members of the Association another twelve months during which professional services again and again were rendered on reimbursement schedules far too meager for the needs of professional life, it may still be consoling, small though the comfort be, that conditions might have been worse. With the national election now a thing of the past, it looks as if the country will settle down to sober, earnest acceptance and trial of some of the newer social endeavors, emphasized so much in recent years, and which, in many instances, are associated more or less with medical practice. Therefore, at the end of the current year and the beginning of the year to come, it may be permissible to breathe the hope of better days and better things.

No business or profession comes into more intimate contact with the trials and tribulations of citizens than medicine. Of necessity, physicians must partake of the joys and sorrows of their patients and, in good degree, prosper or suffer with them. However, in the United States—and certainly in California—there are many things for which to be grateful and hopeful.

In the spirit, then, of mutual helpfulness, the Official Journal, in accordance with past custom, extends again to their fellow physicians, in the name of all members, the Greetings of the Season. May 1937 measure up most fully to our respective needs, good hopes, and desires! Greetings!

HOSPITALIZATION PLANS IN CALIFORNIA

The Physician-Patient Relationship in Medical Practice.—In contrast to other modern-day life, the practice of medicine up to the present time has had as one of its basic characteristics the element of individualization; meaning thereby that the person who is sick or injured does not seek any or a number of physicians, but nearly always a certain physician to take charge of his case; the service in each instance again emphasizing personal, namely, individual medical supervision. The average American citizen, and his family also, when illness or injury come, do not want a mass of advice from a multitude of doctors of medicine, or from a doctor chosen haphazard or at random, but seek, by preference, the individual opinion and service of the one physician whom he and his family and friends have selected, and in whom they have confidence. This interesting patient-to-physician relationship is not a matter of mere custom or habit, but an expression of basic feeling and psychology in evidence among sick and injured persons, from one end of the country to the other. It is typical of American thought and living.

[†] Editorials on subjects of scientific and clinical interest, contributed by members of the California Medical Association, are printed in the Editorial Comment column, which follows.

* * *

Relationship Important in Hospitalization and Medical Service Plans.—Because this physician-and-patient relationship is such a spontaneous and fundamental phenomenon, it must be taken into serious consideration in all plans having to do with medical service in home or hospital. Especially, must this basic correlation never be lost sight of in plans designed to bring greater or more adequate service to portions of the lay population; many of whose members, under modern-day conditions, must face heavy economic and other problems in their efforts to maintain intact the protection and advancement of their family groups.

* * *

Seeming Inability of Mechanization Theorists to Understand.—Theorists and propagandists, who, looking through glasses of their own construction, see only certain phases of illness and the economic problems connected therewith, only too often fail to recognize the important significance of the individualization factor in successful medical practice; propounding their paper theories with self-assurance and satisfaction, and giving the impression at times that they imagine themselves to be modern-day oracles on these matters, when, as a matter of fact, they are not infrequently little more than academic idealologists. In this oracular atmosphere, created by themselves, they do not hesitate to outline and dogmatize on what physicians must do in the present-day world; how they must change their methods of practice, and along what lines their course must be laid for the days to come! Much of the medical service propagandism, as exploited by certain of these lay theorists, comprehends a regimentation and mechanization of medical practice, equally obnoxious to the American patient and the American physician.

The one-sided thinking of some of these visionaries is shown not only in their seeming incapacity to understand how plans leading to mechanization in healing-art care will necessarily produce a lower type of medical service, but also in their overemphasis and exaggerations concerning the vast number of lay fellows in our midst who are supposedly suffering permanent injury from lack of a more universal method of placing physicians on call to all classes of citizens. These thoughts are here presented, as more or less pertinent to what will appear below concerning hospitalization plans in California.

Hospitalization Organizations Now in Operation in California.—At the present time, The Intercoast Hospital Association is giving hospitalization service in the Sacramento Valley and adjacent territory, and in Alameda County, members of the Alameda County Medical Association have also sponsored an hospitalization organization. Each corporation, operating as a nonprofit insurance organization, has been obliged to set aside $25,000 as a protection reserve to clients, and to fulfill other conditions designed to protect policyholders, as laid down by the State's Insurance Commissioner. In Los Angeles and adjacent counties, plans are also in formulation to bring into being a hospitalization system, in this instance, however, to operate as a nonprofit corporation under Assembly Bill 246[*]; and unless legal technicalities prevent, this Southern California plan may be in operation before the close of the year. Under Assembly Bill 246 for nonprofit hospitalization service, the $25,000 requirement is not obligatory. In Southern California more than twenty-five hospitals have signified their acceptance of the plan proposed.

The above plans comprehend hospitalization service on a periodic prepayment basis, the premiums to be paid being such as are within the means of citizens in moderate circumstances. It is to be hoped that the three groups above noted will be successful in their work, and that their areas of service will be extended to practically all portions of the State, where local communities do not themselves promote similar organizations.

* * *

"High Costs of Medical Care" are the "High Costs of Hospitalization."—Many physicians hold that the economic shocks of serious illness and injury, concerning which some of the compulsory health advocates prate so much, have to do, not so much with the fees of medical men and women, as with the heavy expenses incident to hospital care. Therefore, all plans which on a periodic prepayment basis make it possible for citizens of moderate income to protect themselves against this contingency, just as they protect themselves through fire insurance policies, automobile insurance, and health and life policies, would seem to be worthy of earnest consideration and support. Of course, certain matters having to do with clinical laboratory and x-ray service, which today are everywhere accepted and demanded as concomitants of hospitalization, may need satisfactory adjustment; but the difficulties in regard thereto should not be insurmountable.[†]

[†] As the copy for the December issue is being prepared for the press, an interesting news release is received from the Julius Rosenwald Foundation of Chicago, which announces a gift of one hundred thousand dollars ($100,000) to the American Hospital Association for the study and development of voluntary hospital insurance. The item is printed in this issue on page 519.

Action of the California Medical Association: Coöperation Should Be Given.—In this issue of the Official Journal appear * the minutes of the meeting of the California Medical Association Council held in San Francisco on November 7 last, and reference is made therein to hospitalization plans then discussed. Members of the Association are urged to read the same and to maintain an active interest in the efforts to promote satisfactory hospitalization plans in California, and to give whole-hearted coöperation to approved groups. It will save much discussion and worry, in January of next year when the California Legislature again meets, if successful hospitalization plans can be pointed to as actually being in operation over most of the State.

COUNCILOR DISTRICT MEDICAL SOCIETIES: SHALL CALIFORNIA ORGANIZE THEM?

The American Medical Association Plan of Thirty Years Ago.—When, more than thirty years ago, the New England town-meeting form of organization of the American Medical Association was changed into its present order, there came into being for organized medicine one strong national organization, one and only one constituent state association for each commonwealth, and one and only one component society for each county in the United States. Many have been the benefits which have accrued as a result of that reorganization; because, for the first time, the American Medical Association found itself able to amass property and reserve funds (largely through the net income derived from its Journal), making possible, for instance, research councils and departments to aid in the promotion of public health and medical service plans. In a similar manner, the state medical associations took on new leases on life and also, for the first time, began to fulfill analogous functions in their respective territories. For instance, in California, so recently as the year 1900, the State Association—then known under the name "Medical Society of the State of California"—was largely a northern California district organization, the Southern California Medical Society being almost as large and influential in the region south of the Tehachapi. In a number of the larger counties, not one, but two or more additional societies vied with the county organizations in bids for support.

* * *

Good Results of the Reorganization.—The reorganization in 1902 changed all that in California, because, as each county society grew in numbers and influence, so also did the State Association add to its growth and power to serve.

Because of the beneficent results which came about in the 1900-1903 reorganization plans, the medical profession of the United States is today committed to the one strong national organization, one strong state association, and one strong component county society plan; and it may be taken for granted that the American Medical Association is not apt to change its constitution and by-laws to permit a return of multiple organizations, with all their attendant looseness and deficiencies, such as existed in the prereorganization years.

* * *

"Councilor District Societies." — However, there is nothing in the organization plan of the American Medical Association and its constituent state associations that forbids the organization of "councilor district societies," and in a number of states such district organizations have long received active support and have done much good work.

By a "councilor district society" is meant the organization by the counties comprising a councilor district, of a society with an independent identity, but acting in harmony with the state association, as a recognized part of it. A district society may hold annual or semi-annual sessions at places within its territory; at times by it selected. It has its own officers and its sessions last one or two days. Ordinarily, the business meeting is quite brief, and limited to the election and reports of officers and committees. The programs are modeled, in a general way, after those of the state organization, and may stress didactic or clinical expositions, according to conditions. In California two organizations of practically a district type, the Southern California Medical Society and the California Northern District Medical Society (listed on advertising page 6), for years have been carrying on most commendable work.

* * *

How a Councilor District Society Can Serve. Our purpose in writing these lines is to call attention to the following facts: that California is one of the largest states in the Union; that, on that account it is difficult for many members of the California Medical Association to leave their work to attend its annual sessions; that district associations would fulfill a similar function for such members and would promote county society membership and activities in every such district; that such district societies, in a one- or two-day session, could be supplied with clinical demonstrations from their own and extra-district localities, thus aiding the postgraduate work of the State Association; that every district society could be made to be of great value in promoting good fellowship and understanding between the members of the county societies included; and that the community problems of each district territory, such as county hospital and other conditions, could be better solved for such a territorial district if the adjacent counties had opportunities, through a district society, to bring their physicians into more intimate professional and fraternal contacts, and the exchange of views and adoption of policies.

---

* See Council minutes, page 502, items 6 and 12.

Should Not Councilor District Societies Be Promoted in California?—As a matter of fact, if properly organized along simple lines, with skeleton by-laws approved by the California Medical Association Council, and working in full harmony with the State Association and its component societies, a councilor district organization could be made to be one more additional—and with good leadership, a powerful—factor in keeping before the lay public the objects scientific and organized medicine believe in and hope to attain. We suggest that county societies consider the implications involved in a district society for their respective councilor district. Officers of the Association will be glad to give advisory and other aid. If each of the nine councilor districts had such an active organization, the influence and capacity for greater service by the California Medical Association and its thirty-nine component county societies would be largely increased.

STATE ASSOCIATION DUES

Action of the 1936 House of Delegates.—At the annual session of the California Medical Association, held in Coronado on May 25-28, 1936, the House of Delegates approved the recommendation of the Reference Committee that, for the year 1937, the dues of the State Association be increased by $5. The vote by the House of Delegates on the Reference Committee's recommendation was unanimous, not a single one of the more than one hundred delegates, representing the thirty-nine component county societies, asking any questions or making any protest. This unanimity was not to be interpreted as an expression of indifference on the part of the delegates concerning the hardship that might be caused by the five-dollar increase in State Association dues, but rather as a recognition by the seated members concerning the issues confronting the medical profession at the present time—issues which are so vital to the interests of each member that, even though it might hurt to give, there was no other logical course to follow, if the collective and individual welfare of members of the Association were to be adequately safeguarded during the coming legislative year.

* * *

Reasons for the Increase.—Owing to the heavy outlays incurred as a result of the mandatory health insurance survey authorized by previous Houses of Delegates in regular and special sessions, the reserves in the Association treasury have been greatly depleted, and a reëstablishment of an adequate treasury balance seemed necessary.

With a legislative session in the foreground for the year 1937, it may be taken for granted that attempts will again be made to launch health insurance and open-county-hospital legislation upon the citizens of California. As a matter of fact, copies of certain proposed bills drafted by lay and unknown sources have already been placed in circulation and propagandized.

It is not possible to forecast in advance how much effort and time may be necessary to keep in touch with the progress of such proposed legislation, as it takes its course through assembly and senate committees and on the floors of the chambers, but that it will need constant surveillance is self-understandable. Also, that the work is so onerous and time-consuming, that members of the Committee on Legislation and Public Policy cannot be expected to neglect the personal practice of their profession to render gratuitously, or otherwise, the full service which will be necessary. The costs of the clerical and executive personnel which the Association is called upon to engage, to look after work of this kind, are not inconsiderable items.

* * *

Interests at Stake.—It is true that one should rebel against expenses of this type, brought into existence through the desire to safeguard public health and medical practice standards, but academic discussion would only lead to disaster; and make possible, in all probability, the enactment of poorly matured legislation that might not only mean a monetary loss to every California Medical Association member of many, many times the five-dollar increase in dues during the coming year, but which in future years might bring about radical and demoralizing changes in medical practice in California; with financial and professional retrogressions, at this time difficult to even visualize.

* * *

Increase for One Year Only.—Matters such as the above, as well as other responsibilities of the Association, explain the unanimous approval by the Coronado annual session delegates of the five-dollar increase in dues for 1937 which, it is hoped, will not be necessary in the subsequent years; and which could only be continued with the sanction of the delegates elected by the component county societies. So that, in the last analysis as in the past, the component societies, through the delegates which they elect, will have full power in the premises, so far as State Association dues in future years are concerned.

Other State Association and Component County Society News.—Additional news concerning the activities and work of the California Medical Association and its component county medical societies is printed in this issue, commencing on page 502.

Our chief enemies at present are heart disease, cancer, pneumonia, tuberculosis, and syphilis. If the full facts are known, as Doctor Osler said, syphilis would probably come first. Syphilis is the biggest killing disease in the community. It and tuberculosis are undoubtedly the greatest present contributors to the total mortality prior to the approach of old age. By the removal of tuberculosis and syphilis, most of the preventable deaths from the age of 15 to 65 would be avoided.—Sir Arthur Newsholme, M.D.

EDITORIAL COMMENT[†]

CAPILLARY RESISTANCE

Two methods have been applied in the study of capillary resistance. In the earlier method introduced by Rumpel and Leede, a constricting band is applied to the arm for a period of time, and the occurrence of petechiae in the arm distal to the band (particularly in the cubital fossa) is noted. Göthlin[1] recently applied this method in a controlled manner in studying the occurrence of latent scurvy in school children in Sweden. The method as applied by Göthlin is a reliable index of capillary resistance, but is cumbersome and time-consuming.

In the second method, originated by Hecht,[2] a negative pressure is used applied to the skin through a suction-cup combined with a mercury manometer and a vacuum pump. Hecht used the test chiefly in exanthema. Wiemer[3] applied the method extensively, noting the variability of capillary strength in different skin areas and in various pathological states. He considered that different influences might reduce the capillary strength by injuring the capillary wall. Among these were certain poisons, bacterial toxins, metabolic products and, of course, vitamin C deficiency. Further certain physiological states, as menstruation and endocrine disturbances such as exophthalmic goitre, were thought to reduce the capillary strength by their influence upon capillary tonus.

Recently Dalldorf[4] modified an instrument devised by da Silva-Mello,[5] in which a spring manometer was substituted for a mercury instrument. It is this instrument which we have used. The test is simple. A surface of skin is thinly smeared with vaselin, the cup is applied and the desired suction made. This negative pressure is maintained for one minute by closing a valve leading from the pump. Our application of the test has been chiefly in rheumatic fever and rheumatoid arthritis, diseases in which we feel a factor of vitamin C deficiency may be concerned.[6] In these diseases we find the capillary strength reduced. In most instances the capillary strength has risen in cases maintained on a high vitamin C intake. This rise has often required several months, indicating a delayed restitution of the capillary wall. The capillary resistance is expressed in terms of the lowest negative pressure (centimeter of mercury), maintained for one minute, which will produce macroscopic petechiae. Although the test may be an index of latent scurvy as proposed by Dalldorf, there are certain limitations of the method. As he has noted, there are unexplained individual variations encountered, and undoubtedly other factors which impair capillary walls may reduce the capillary resistance. It may be that in some diseases vitamin C deficiency may be a contributory and not the sole factor in reducing the capillary resistance. However, an estimate of the strength of the capillary wall is of potential service in the study of disease. This is particularly true if the capillary strength proves to parallel permeability. Dalldorf has set the "normal" level of capillary resistance at 35 centimeters of mercury in testing the upper arm. We feel that the test should not be interpreted too narrowly. Positive readings below 20 centimeters of mercury we consider evidence of reduced capillary strength. In some instances such reduction appears to have no significance. Our tests have been done on the volar surface of the forearm in some cases, and the upper arm in others. The upper arm readings are almost uniformly somewhat lower. It would seem that a modification of the test might be of value in detection of latent edema.

VITAL CAPACITY DETERMINATION: WITH PARTICULAR REFERENCE TO ITS VALUE IN HEART DISEASE

Borelli first measured the vital capacity of the lungs in 1679. It was studied intermittently after that until a truly scientific study of results on 3,000 people was published by Hutchinson in 1846.[1] His paper marked the beginning of the present epoch in the history of the test. During the World War an easy method for the estimation of physical fitness of large numbers of men was needed and vital capacity was frequently used as an indicator. Dreyer[2] reported this work and pointed out that it was a decisive factor in admission to the British Flying Service. After the war the center of interest shifted to America, due largely to the work of Peabody and Wentworth[3] in Boston. Since that time the test has been the subject of extravagant claims and severe criticism, but certain definite values have allowed it to survive both extremes of thought.

FACTORS THAT INFLUENCE THE VITAL CAPACITY

These are, of course, important in judging the value of the test.

1. *Age.*—Children less than adults; definite tendency to drop after the age of 50 to 60.
2. *Sex.*—Slight difference in early years, and a definite difference after the age of 15. Men are higher than women.
3. *Physical Fitness.*—Athletes may be 100 per cent more than their theoretical normal. Occupations have an effect, and laborers have much greater vital capacities than office workers.
4. *Body Measurements.*—Weight, height, stem length, chest circumference, chest capacity, and body surface all affect the vital capacity. The most satisfactory standard tables are calculated from body surface.
5. *Race and Nationality.*—Chinese and Filipinos lower than Westerners.
6. *Posture.*—Results are about 5 per cent lower with the patient reclining than when standing.
7. *Pulse.*—Increased rate causes a slight decrease, more marked in definite heart disease.
8. *Muscular Fatigue.*—Causes slight decrease.
9. *Hyperthyroidism.*—Decrease has been reported, more marked with cardiac involvement.
10. *Increased Abdominal Pressure.* — Pregnancy has only an occasional slight effect.
11. *Deformities of the Thorax.*—Fixation or encroachment upon the intrathoracic space has a definite effect.
12. *Pleural and Pulmonary Conditions.*—Pleurisy, pneumothorax, emphysema, asthma, bronchitis, lung abscess, pneumonia, new growths and tuberculosis all definitely lower the vital capacity.
13. *Cardiac Conditions.*—These have a marked effect, as discussed below.
14. *Extraneous Factors.*—Psychic factor important, as concentration and utmost effort are necessary. Temperature, atmospheric pressure, and vapor pressure all have slight effect.

CARDIAC CONDITIONS

Vital capacity determinations are of particular help in following the progress of cardiac patients. Reduction closely follows the clinical condition, and occurs before râles can be heard at the lung bases in congestive failure.

Repeated determinations are of the greatest value and show (1) impending failure, (2) effect of treatment, (3) point of maximum response to treatment, and (4) possible indications of the level of cardiac tolerance. There is a marked correlation with dyspnea. In "effort syndrome" the vital capacity is usually normal.

METHOD

Tables of normal standards calculated from body surface are considered the most reliable, except in extremes of emaciation or obesity. The calculation is as follows: Body surface (sq. M.) × 2,500 = estimated vital capacity in cubic centimeters for men. Body surface (sq. M.) × 2,000 = estimated vital capacity for women. The body surface can be easily determined from the patient's height and weight, using charts prepared by Boothby and Sandiford.[4]

The test is performed with the use of a spirometer which measures the amount of exhaled air. The patient is always in the same position (usually standing), all clothing about the thorax is loosened, and three attempts are made, each after the deepest possible inspiration. The highest reading is recorded.

Most of the points in this article are adequately discussed in a monograph by Myers[5] which also contains a complete bibliography.

Report of British Medical Association on Immunization.—More than a year ago, the British Medical Association appointed a committee, consisting mainly of health officers and pathologists, to prepare a scheme for informing the public regarding the protection afforded by the various methods now available of immunization against diseases.

Diphtheria.—The committee states that diphtheria is not less prevalent than formerly, but is less fatal. Isolation and sanitary measures have failed to control it, and it accounts for three thousand deaths annually. Active immunization is confidently advocated. In children under the age of eight years the preliminary Schick test may be omitted, since the great majority may be assumed to be susceptible, but as a test of success should be performed from one to three months after the immunizing course. For children any of the preparations known as toxoid, toxoid-antitoxin mixture, toxoid-antitoxin floccules and alum toxoid may be safely used, but for adults preference is expressed for toxoid-antitoxin mixture or floccules. On the average, 95 per cent of immunized persons are still Schick-negative from three to five years after immunization.

Scarlet Fever.—Scarlet fever still presents difficulties in preventive medicine. The death rate has fallen remarkably, although the incidence has altered little. The Dick test is held to be very reliable. Immunization should at present be reserved for hospital staffs and children in a residential school where an outbreak has occurred. Two methods of immunization are used: (1) In England most workers use weekly or fortnightly injections of 500, 1,000, 5,000, 10,000, and 20,000 skin test doses. (2) In recent years the tendency has been to use a higher dose. In the United States the Dicks and others give doses running up to 80,000 or 100,000. By slow graduation of dose, reactions may be almost entirely avoided. Probably from 2 to 10 per cent of the immunized revert to the Dick-positive state within a year.

Measles.—Passive immunity to measles can be produced by the use of convalescent serum or blood and by adult serum or blood. It may be used for postponing the danger of infection to a more opportune time or for mitigating the attack. Convalescent serum is the material of choice and should be given in the first five days after exposure for complete protection. Administration between the fifth and ninth days, or half dosage during the first five days, is used for modifying an attack.

Typhoid.—The work of Wright and Leishman during the war resulted in the production of a typhoid vaccine widely and successfully used. In the years that have followed, modifications have been introduced into the technique of manufacture. Saline suspensions have replaced broth emulsions. Work in the department of pathology at the Army Medical College has resulted in the production of a vaccine containing 1,000 million B. typhosus, 750 million each of B. paratyphosus A and B. paratyphosus B in 1 cubic centimeter of 0.5 per cent phenolated saline solution. Adults are given 0.5 cubic centimeters after ten days by 1 cubic centimeter.

PRACTICA MEDICI MODERNI*

By Chauncey D. Leake, Ph.D.
San Francisco

When Dr. Fletcher Taylor, the genial chairman of the 1936 Section of General Medicine of the California Medical Association, persuaded me to discuss with the Section some non-technical aspects of modern medical practice, he failed to tell me that he was relinquishing his traditional prerogative of delivering a chairman's address in order that I might talk. To admit surprise is to admit only the mildest of my feelings on discovering this fact when the program of the meeting appeared. Here was a humbling example of that very modesty, trustfulness, and friendliness which Doctor Taylor had suggested might form an appropriate theme of part of my remarks. I am excitedly conscious and stammeringly embarrassed by the responsibility placed upon me. But there is no greater obligation imposed on our conduct than for us to try to justify the confidence others may place in us. However vagatonic, therefore, my trial may be, I hope it may have your sympathetic indulgence.

FOUR IMPORTANT FACTORS IN MEDICAL PRACTICE

In looking broadly on the practice of modern physicians through appreciative and academic eyes—slightly astigmatic, I fear—I have been struck by four formidable features which I wish to offer for your consideration; three of them as old as medicine, the fourth very new. First, there is the ancient problem of holding together for effective teamwork that spirited and often poorly harnessed pair, the scientific and the artistic phases of practice; second, there is the equally ancient problem of developing medical etiquette in accordance with sound ethical principles, in which I wish to point out that professional relations are most satisfactorily promoted on the basis of gentlemanly friendship; third, we must pay our respects to the revival of another ancient medical problem regarding intense specialization; and, fourth, we should consider the consequences of a wholly new medical problem associated with the rise of sound and applicable methods of preventive medicine, in regard to which I want to suggest a way by which a practical incentive may be provided for its effective practice. Here is enough to chew over for a long time, and it is tough meat. But by pulling in our belts, we may strengthen our stomachs to digest it. If we get a bellyache, Doctor Taylor has brought it upon us.

ART IS LONG

Modern medical practice is sharpening the focus on the traditional but not always convivial union of science and art in medicine. The art of medicine has predominated until recently. But now the scientific part of the team has almost run away with the wagon, and it is time to pull in the reins and get the team working together again. The scientific part of medicine consists of the factual data accumulated by observation, experience, and experiment regarding the cause, recognition, natural course, treatment, possible outcome, and prevention of disease. The artistic part of practice lies in the application of this knowledge to the special problem offered by an individual patient in the effort to bring into or preserve that patient in the ideal state of health conceived for him by the physician. About the factual knowledge there is no argument. It is observable or reproducible. The data may be explained in various ways, but the facts remain the same, irrespective of anyone's opinion. But the artistic effort is entirely individual, and although all physicians are artists, no two physicians will solve the same artistic problem in the same way any more than two musicians will play the same composition in the same way, or two painters paint the same scene identically. Styles may be similar. They are conditioned by the fashions and vogues of the moment. But the essence of art is judgment and choice. The soundness and effectiveness of this procedure for a desired end is acquired only by long experience. Most of the science of medicine may be learned in the four years of medical school, but the rest of a physician's life may still find him deficient in the art. The first aphorism of a leader of a great school of medicine is to the effect that art is long and life is short.

We may find an easy illustration of the problem in connection with drugs—that is, chemicals used for the diagnosis, prevention, cure, or alleviation of the symptoms of disease. The actions of these chemicals may be determined with a considerable degree of accuracy, now that we have sound bioassay methods as developed by Trevan and Burn. About these demonstrable actions there is no argument. They remain factual in spite of how they may be explained, or in spite of what anyone may think of them. But to apply these actions to a specific problem in connection with an individual patient—this calls for judgment and artistic skill of a high order! Judgment in any artistic problem is a matter of discriminating choice. This can only be developed by long experience. To use drugs wisely in medicine demands such judgment. The primary principle, of course, is to be sure that the drug hazard does not outweigh the disease hazard, no matter for what purpose the drug may be used. *Primum non nocere* remains now, as in centuries past, a cardinal principle of medical practice.

My plea to you is to remember that the factual knowledge may be obtained from disinterested professional sources, such as universities, reputable texts, journals and monographs, but not from detail men or specious advertising, either of commercial houses or clinics. In failing to use this discriminating judgment, physicians have shown themselves to be as gullible as any other class of humanity.

---

* From the Pharmacological Laboratory of the University of California Medical School, San Francisco.

Read before the General Medicine Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

My appeal to you is to cultivate your great art in every way. In the attempt to achieve a desired result, three steps are important. First, there must be a clear recognition of the desired end, a clearly visioned *ideal* of what is wanted; second, the *knowledge* of how to work the refractory material of the sick body to attain this end; and third, the *skill* or technique to carry out this work.

No sculptor, not even Rodin, is a greater artist than the plastic surgeon who carves a semblance of human expression from the wreckage of a shell-torn face; no musician, not even Beethoven, is a greater artist than the physician who develops a harmony of adjustment from the dissonances of a psychopathic personality; no painter not even a Romney, whose pink-cheeked maidens brighten every big gallery, is a greater artist than the physician who can put the bloom of good health in the cheeks of his patients; no dramatist or actor is a greater artist than the physician who daily plays his rôle in the everlasting and thrilling drama of the lives and deaths of his patients.

My plea, then, is to study and practice your art. Whatever scientific background you may have is merely to make your art more effective. Study art in all its many forms. All good physicians are good artists. It is not merely a coincidence that so many physicians are painters, musicians, novelists, and poets.

MEDICAL ETHICS AND ETIQUETTE

These considerations have important moral implications. Osler emphasized that the Hippocratic association of *Philotechnia* with *Philanthropia*—love of the art and love of humanity—is an ancient recognition of what is a fine idealism of more than merely academic interest. Love of the art promotes love of humanity, and vice versa, and in either case science also. Beauty, goodness, and truth may be for us, as for the Greeks, an idealistic and intellectual trinity of great significance; as George Sarton is showing in his humanistic studies on the history of science.

It is in the matter of personal conduct that the artistic qualities of the good physician may be most effectively expressed. Personal conduct is not easily based on rules, although these help to set a standard of good taste or conventional etiquette. Most of what is called "medical ethics" is concerned with merely the etiquette of professional conduct. The current rules of "medical ethics," derived from Thomas Percival's code of 1804, bear a striking similarity to trade-union rules, for their chief purpose seems to be the enhancement of the prestige and success of the profession and its members. This is a form of hedonism; that is, it is based on the motive of personal pleasure. It is quite different in its purpose from the Hippocratic association of *Philotechnia* and *Philanthropia,* which is an expression of "idealism," that is, conduct motivated by a desire to promote the welfare of society as a whole. One of the chief difficulties in the personal-conduct problem of modern medicine is the clash between the idealistic ethics it professes and the hedonistic ethics which it practices. Years ago I tried to point out the factors responsible for the situation;[1] but, naturally, the profession paid no attention to my sophomoric effort. Now, with society pressing the issue, it is becoming more acute; but I fail to notice that the profession is any more conscious of the fundamental problems of ethics than it ever was. It might indeed be helpful to get some advice from scholars who know something about ethics, like men of the caliber of Professor Warner Fite, for example. There are only a few of them, for only a few of our universities still think ethics worthy of prominence in the curriculum. The recent pronouncement of the official agency of the American Medical Association on this subject[2] is what one might expect. I doubt if more than a few dozen members of the Association read or studied it. To any with intelligence who did so, its inconsistencies must have been apparent, even though it made a great show of erudition with copious (but prejudicinally selected) documentation. Medical ethics should really be a simple matter. In its relations with society, the profession of medicine, as it exists now, must follow a truly idealistic ethics, or society will destroy it.

In the individual relations between its members, medicine should promote the ethics of friendship. Friendship implies all that is noble without being sentimental. From good friends one is certain to derive three great things: tolerance, comfort, and inspiration. Even to become friends, let alone remain so, the cultivation of tolerance for each other is the first essential. Tolerance promotes understanding and sympathy. Tolerance leads us to appreciate that we are all made of the same common clay, a reflection that comforts the young and promotes patience in the old. Tolerance in the practice of medicine is essential, since the practice of medicine is an art, and there is no uniformity of opinion on anything artistic. Tolerance among friends does not imply acquiescence in anything falling short of an ideal; quite the contrary! Tolerance makes possible the recognition of the mote in one's own eye, and thus makes one more willing to forgive the beam in one's neighbor's. Tolerance among friends is reciprocal, and promotes comfort and inspiration.

Friendship has little meaning unless it provides comfort and inspiration—comfort in the daily defeats we all suffer, and inspiration for doing our best in the daily tasks we all must face. From the comfort one may feel in a sympathetic friend usually arises a mutual feeling of trust and confidence that becomes the strongest incentive to its own justification. The greatest moral force one may feel is the necessity of justifying the faith placed in one by one's friends.

In the daily burdens of medical practice, professional friendship may be the greatest incentive to the best in medical ethics. Then, in a truly idealistic manner, personal advantage of any sort becomes willingly sacrificed for the welfare of society as a whole. Genuine friendship in the profession eliminates any necessity for the formulation of rules of etiquette. Mutual respect among friends, built by tolerance, comfort, and inspiration, promotes the qualities of gentlemanliness. We all know what gentlemanly conduct means. There is no need to establish rules and definitions by which it may be judged. Perhaps that is why Dr. St. John Roosa proposed, during the squabble over "medical ethics" in the New York State Medical Society in the eighties, that the only rule need be that a member conduct himself as a gentleman. Friendship makes this easy.

SPECIALISM

In modern medical practice appear two difficult problems—specialism and preventive medicine. The former is an ancient relic of the ancient tendency of vain men to furnish themselves with false fronts. It is inherent in the vanity of human character, and from Babylonian times has never been able to divorce itself, in the eyes of the intelligent public at least, from a taint of quackery and hypocrisy. Specialism is, unfortunately, too often associated with pride, arrogance, and high fees. Notwithstanding national boards of certification, international societies, and other dignified protestations of limited (and therefore presumably superior) practice, the taint continues. It will continue until the general health adviser, the general practitioner—the friend, counselor and confidant of the family—is returned to that dignity of status where the specialist's fee will be no more than his. Can this be accomplished? Easily. Let the general practitioner take preventive medicine as his specialty—and give him a financial incentive to practice it. Let the specialist keep his financial interest in people's sickness, but let the general practitioner derive his income from keeping his patients well—on a retainer-fee basis. The public has always had a great interest in the presumed Chinese method of practicing medicine.

PREVENTIVE MEDICINE: THE GENERAL PRACTITIONER'S SPECIALTY

The avowed ideal of the profession of medicine is the prevention of disease. From the first year of his medical training, this is the goal toward which all the efforts of the future physician are supposed to be directed. But as soon as he reaches clinical training the average medical student has already been made so callous by his professional elders that he cynically shrugs off any personal responsibility in preventive medicine by leaving it forever after to official agencies—meaning the overworked and underpaid governmental public health officials. The average doctor pays only lip service to their work. The average doctor is well aware that the effective application of preventive medicine reduces his practice. The average doctor knows, but dares not admit, that his income depends on the presence of sickness. He has a financial interest in the illness of his patients, and no monetary stake in the health of his clients. It is impossible under these circumstances for a practicing physician honestly to support measures in behalf of public health or preventive medicine. It is this amazing discrepancy between what the organized medical profession preaches and what its individual members practice that is so disconcerting to intelligent laymen.

The effective practice of preventive medicine by the individual physician is possible. While it is not traditional, and while current custom may be against it, every moral factor is favorable for it. It can be done without invoking the paper specter of state medicine or the bogey of medical insurance, or the presumed difficulties of contract practice. It can be done in such a way as to preserve and enhance the individual, personal relationship between a doctor and his patient which group practice, a jungle growth of specialism, and a commercially efficient office and hospital management, have almost destroyed.

The effective practice of preventive medicine is possible. A physician may make a personal individual arrangement with a patient. In accordance with his judgment on the patient's physical condition, family and business environments, and his general attitude and position, the physician may, for a fee, varying with these conditions, agree to examine the patient as often as he thinks expedient, give such advice or prescriptions as seem warranted, and make such house calls as he may think wise. The agreement should not include special diagnostic services, emergency affairs, hospitalization, or operative or other special procedures. The physician in such an arrangement would be a health adviser on a retainer fee.

Under the genial leadership of Langley Porter, such a system has been followed in pediatrics in San Francisco for over twenty years. Its wide extension and popularity are sufficient evidence of its practical success. It is amazing that so simple a method of providing a practical financial incentive to the effective practice of preventive medicine has not been universally advocated. Under such a system it is obviously better for the doctor to keep his patients well than to have to give treatment when they are sick. The doctor gains in time, which ideally would be used to improve his knowledge and not merely his golf. The proposed scheme is so simple, and sounds so reasonable, that there must be something wrong with it which has prevented its adoption long ago. The medical profession has had the example of the legal profession in practicing preventive law for many years. In San Francisco, I am reliably informed, about three-fourths of the income of the more reputable lawyers is derived from retainer fees operating to keep both average individuals and families, as well as estates and large corporations, from court or other legal complications.

To my surprise I have been unable to find any intelligent medical opinion which can point out a serious disadvantage or fallacy in the proposal, except a vaguely expressed fear that the physician may occasionally be imposed upon. If the desired relation of friendship and mutual trust existed between physician and patient, abuse in either direction would be unlikely, and even if it were to occur, either party could terminate the agreement.

IN CONCLUSION

As always, I have talked too much and said too little. My appraisal of modern medical practice may be criticized on the ground that, since I am not a physician, I know nothing about its problems; but not on the ground of lack of sincerity or sympathy. I have tried to discuss four formidable necessities of modern medicine: first, the need of correlating the scientific and artistic phases of practice; second, the need of developing "medical ethics" in a manner consistent with idealistic ethical theory; third, the need of raising general practice to the dignity of specialism; and fourth, the need of providing a monetary incentive to the effective practice of preventive medicine—preventive medicine as the general practitioner's specialty, practiced on a retainer fee basis. I hope this tough meat which you have been given to chew over will not jeopardize your kind friendship toward me. Your tolerant friendliness means much in comfort and inspiration to me, and I hope that I may reciprocally justify such a feeling in you.

ACUTE APPENDICITIS*

A CLINICAL REVIEW OF ONE THOUSAND CONSECUTIVE CASES

By George K. Rhodes, M.D.
Walter Birnbaum, M.D.
and
Maurice J. Brown, M.D.
San Francisco

Discussion *by Charles T. Sturgeon, M.D., Los Angeles; H. Glenn Bell, M.D., San Francisco; Edwin M. Taylor, M.D., Oakland.*

It is the purpose of this paper to show the need for early operation in acute appendicitis, and to emphasize the application of certain measures in its treatment. The number of publications concerning appendicitis is increasing (Table 1); the renewed interest in the subject is likewise reflected in the serious discussion, in larger medical centers, of various controversial views. The present discrepancies in the operative mortality rate point toward some basic deficiencies in the present mode of treatment. There yet remain many controversial questions pertaining to surgical intervention, among which some of the most important are the time of operation, the necessity for drainage, the type of incision, the kind of anesthesia, etc. In order to justify our present methods of procedure, we have analyzed the consecutive cases of one thousand patients surgically proved to have acute appendicitis who underwent immediate operation on the emergency service of the San Francisco Hospital. This series is comprised of patients treated on one service, according to the same policy, over a ten-year period. During this period, the operative mortality in all types of acute appendicitis reported here was 3.6 per cent. In gangrenous appendicitis without perforation, it was 1.9 per cent, and with perforation, somewhat higher (Table 2). These figures compare favorably with those of other American and European clinics[1] (Table 3).

ONE THOUSAND CONSECUTIVE CASES OF ACUTE APPENDICITIS

Most of the emergency surgery for the indigent is done in the San Francisco Hospital (bed capacity 1,000) and, as has been pointed out by others, the type of appendicitis seen in this stratum of society is usually of the variety most difficult to treat. The patients, of poor physical stock, are more likely to delay in seeking medical attention and to indulge in self-medication and purgation than are other classes.

FOUR GROUPS

We have divided our cases into four major groups, on the basis of pathologic changes proved at operation. These groups, with their respective mortality rates, are:

	Drained Per Cent	Not Drained Per Cent	Total Per Cent
1. Simple acute appendicitis	......	......	0.84
2. Gangrenous appendicitis, without perforation	9.0	0.9	1.9
3. Gangrenous appendicitis, with perforation	10	2.4	8.8
4. Appendiceal abscess	......	......	5.3

This classification has been chosen because of its simplicity. One great difficulty, in comparing statistics, is the lack of uniformity in classification by various authors, and the inaccurate or incomplete statement of the pathologic changes actually present.

DIAGNOSIS

The preoperative diagnosis was seldom in doubt. The classical history of abdominal pain, followed after a few hours by increasing signs and symptoms of localizing peritonitis, was the usual observation.

A good history and a careful physical examination are most important. In our experience, temperature and blood count seldom are the determining factors in diagnosis, because of their

Read before the General Surgery Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

TABLE 2.—*Mortality by Type*

Type	Description	Cases	Total Mortality Per Cent	Mortality Per Cent, Excluding Deaths and Not Resulting from Appendicitis
I	Acute, simple	355	0.84	0.65
II	Gangrenous, nonperforated	256	1.9	1.9
III	Gangrenous, perforated	202	8.8	7.4
IV	Appendiceal abscess	187	5.3	4.4
	Total	1,000	3.6	3.0

wide variation in identical appendiceal pathologic states.

Most errors and delays were made in the true pelvic and retrocecal types of appendicitis. In both instances, while the prodromal history, etc., may be suggestive, there is little or no evidence of parietal peritoneal involvement. The pelvic appendix often produces signs and symptoms referable to the bladder and rectum, such as frequent stools and dysuria. Further, in pelvic appendicitis the early signs and symptoms of peritonitis may be those referred to the left lower quadrant. The presence of a tender mass rectally is sufficient to substantiate the diagnosis of pelvic appendicitis in any suspicious case. The most significant sign in retrocecal inflammation is tenderness in the flank, with little or no rigidity of the anterior abdominal wall. Because of the proximity of the right ureter to the inflammatory process, one often finds signs and symptoms suggestive of disease of the right upper urinary tract.

THE TIME TO OPERATE

Perhaps most controversy arises concerning the problem of the time to operate. Agreement is general that, in the early stages of acute appendicitis, operation should be performed immediately. Methods differ, however, for those patients who are seen late—that is, after the third day. From the third to the sixth day of the attack is the most dangerous period. Stanton,[2] in an analysis of 60,000 cases reported recently, shows that the mortality in that period is from 8 to 12 per cent. During this time, either the process is subsiding or peritonitis is present. As Richardson[3] has said, "It is too late for early operation and too early for late operation." Such distinguished surgeons as Murphy,[4] Fowler,[5] and Ochsner[6] in the United States, Sherron[7] in England, and Fromme [8] in Germany, have defended expectant treatment in certain of these difficult types of appendicitis. It has been said, no doubt correctly, that it is the unintelligent application, and the abuse of the conservative regimen, which have done more harm, and that it is the choice of unsuitable cases which has brought this principle into disrepute. Wilkie[9] said: "Those who say that there is no state in which one should not operate may be skillful technicians, but they are not surgical pathologists." Despite such formidable opinion to the contrary, we feel strongly that appendicitis in any stage of development, except for a small group of cases to be mentioned later, requires immediate surgery. To substantiate or disprove this statement, the following questions must be answered:

TABLE 3.—*Comparison of Results of Treatment of Acute Appendicitis in Large European and American Clinics*

	Operative Mortality Per Cent
European clinics	5.5
American authors	5.10

1. Can the pathologic changes present be determined accurately enough before operation to warrant delay?
2. Although it is true that late cases have a high mortality, has it been convincingly shown that the mortality is actually higher with operation than without it?
3. Is the low mortality in this series the result of any factor other than the choice of the time to operate?
4. When is the time to operate?
5. Which patients should not be operated upon?

1. *Can the pathologic changes be determined accurately enough before operation to warrant delay?*

A review of the literature shows a cumbersome number of statistics which seem to support widely diverse conclusions. This may be explained by the lack of uniformity in the classification of types of appendicitis, and the clinical basis upon which the classification is made. From clinical study alone it is almost impossible to determine accurately the stage of the changing pathologic process in acute appendicitis. Not everyone can, as Deaver[10] has said, "put my ear to the abdomen, lay my hands upon it . . ." and arrive at a clear conception of what is occurring beneath the abdominal wall. Kennedy,[11] discussing what he derisively terms "the physiologic surgeon," and asks: "What is this quiescent stage of the physiologic surgeon? It can be summed up as a mistake in his assumption as to the extent of peritoneal involvement, so that when the physiologic surgeon puts his patient on the waiting list for the subsidence of the acute symptoms ere he considers the patient surgical, *he is wrong,* not only in his idea of the extent of the pathologic involvement, but he is permitting a very local condition to become a very diffuse one. He is outraging the law which gives success in perforative lesions of the abdominal cavity, namely, the earliest possible

Table 4.—*Seventy-five Preoperative Diagnoses*

	Local Pathology Change	Location of Appendix	Question of Rupture	Extent of Peritonitis	Abscess Formation
Per cent correct	33.3	40	58.6	61.5	31.3
Per cent incorrect	53.3	49.3	41.4	34.6	14.6
Not noted	13.3	10.6	0	0	4

operative hour. . . . The physiologic surgeon never gets an opportunity to check up on his mistakes; he never learns the true extent of the pathologic lesion other than from the postmortem room."

In order to ascertain the accuracy of preoperative diagnoses, various members of our staff committed themselves in writing before the patient went to surgery. The results of seventy-five opinions were enlightening, in that in estimating "perforation" or "nonperforation," the percentage of error was 41.4; in estimating the extent of peritonitis (*i. e.*, whether it was local or general) the percentage of error was 33 (Table 4).

The underlying pathologic condition is complicated, and is different in each patient. In many of our patients, rupture occurred within six hours, while in a larger number, perforation had not occurred after seventy-two hours. As subject to criticism as this tabulation may be, it does illustrate the fact that in many cases, at least, no conclusion may be drawn with any degree of certainty as to the underlying pathologic factors. Even if such information were obtainable, it is not possible to know in which direction progress is taking place. As Gile and Bowler[12] said: "In delaying surgical intervention in early peritonitis with a rate of 6.5 per cent, we had no preoperative basis for prophesying whether the transfer would be to abscess formation and a mortality of 3.33 per cent, or to general peritonitis with a rate of 36.4 per cent." This is the crux of the situation. The underlying pathologic change is different in each case of appendicitis. It is this underlying change and not the element of time which determines the outcome. The physical evidence of peritonitis is also a very variable factor depending upon the location of the appendix, the pathologic condition, and the reaction of the patient. We are convinced that even competent observers cannot estimate accurately the pathologic condition preoperatively, and hence it seems illogical that we should pursue a course of expectant treatment on such questionable premises. Furthermore, there was an error of 100 per cent in two of our recent cases, in one of which the condition was an acute Meckel's diverticulitis; in the other, a volvulus of the cecum with early gangrene. It is obvious that delayed treatment of such patients would have been disastrous.

2. *Although it is true that late cases have a high mortality, has it been convincingly shown that the mortality is higher with operation than without it?*

The answer to this question is not difficult. As stated above, statistics are exceedingly numerous in the literature on appendicitis; they appear to point in opposite directions. Since the same patient cannot, on the one hand, be operated upon in a certain stage of the disease and, on the other, be accorded conservative treatment at the same stage, no approach to a scientific decision may be reached. Furthermore, the criteria by which the classifications were evolved vary so widely that one is never sure of the comparableness of the different series. The issue is confused further by variations in the classifications themselves. Ochsner[13] has said that he obtained 90 per cent recoveries by the use of his conservative method in a type of case which formerly had the same percentage of deaths. It is to be noted, however, that conservatism was supplemented by meticulous adherence to his fourteen dicta which included the Fowler position, the administration of fluids, use of morphia, starvation, etc. Had these points been followed in connection with operation, the mortality rate might have been different in the earlier series.

3. *Is the low mortality of this series the result of any factor other than the choice of the time to operate?*

Intelligent preoperative and postoperative care bear a direct ratio to mortality. A few hours' delay before operation frequently is recommended in order that the patient's general condition may be improved. As Arnheim and Neuhof[14] stated: "The trip to the hospital may have been long and difficult, the patient may arrive in a highly excited state, the patient may be partially dehydrated. These are some of the factors which often lead us to wait a few hours or longer before proceed-

Table 5.—*Operative Mortality in Representative and Comparable Series*

	Cases	Mortality Per Cent
San Francisco Hospital	1,000	3.6
Boland (Atlanta)	4,270	4.4
Keyes (St. Louis)	771	3.8
Fairchild (Woodland)	541	4.4
Bower (Philadelphia)	5,121	5.9
Reid (Cincinnati)	2,003	8.5

Table 6.—*Drainage Comparison With Russian Series (1936)*

	San Francisco Hospital	Leningrad Institute for Quick Aid
Number of cases	1,000	1,944
Per cent of abscesses following drainage	13.2	7.8
Per cent of abscesses without drainage	2.9	3.3
Per cent of mortality following drainage	9.8	17
Per cent of mortality without drainage	1.4	1.5

ing with operation in the second and third day of attack in acute appendicitis."

If early peritonitis is noted at operation, the accepted treatment of peritonitis is begun at once before paralytic ileus develops. The early and continuous use of the Connell suction is a valuable adjunct to postoperative treatment. It creates a negative pressure which prevents gastric dilatation, paralytic and mechanical ileus. If the apparatus functions properly, the need for enterostomy becomes very limited. Fowler's position and hot massive abdominal stupes also aid in the patient's satisfactory convalescence. The intelligent use of pitressin-like compounds has also proved valuable in the treatment of paralytic ileus. The early use of cathartics or enemas after operation has dangerous potentialities, and these measures are never employed by us. Recently we witnessed elsewhere two fatalities which were the direct result of postoperative enemas. In these, the friable cecum was ruptured at the site of the appendectomy.

4. *When is the time to operate?*

For the reasons stated above, it is our conviction that immediate operation is essential. This has long been axiomatic in the treatment of the early cases. We believe that, with few exceptions, this same dictum should obtain in all cases and types of acute appendicitis regardless of the period in which the patients are first seen, and that this policy is sound is evidenced by our mortality rate, which compares very favorably with those reported in the literature (Table 5).

5. *Which patients should not be operated upon?*

Those patients whose condition is such that they are not likely to survive the ordeal of the operation itself are not operated upon immediately. This group includes the patient who is in the latest stages of the disease. It seems likely that many of the papers which advocate expectant treatment refer to this type of peritonitis. If this is so, we are in agreement with them; the most immature surgical judgment would not dictate operation in such cases.

Our own experience places patients with the following signs and symptoms in this group:

(*a*) Those in poor general physical condition either from coincidental disease, such as a cardiac or pulmonary lesion, or those debilitated from long sepsis or toxic state.

(*b*) Those with peritonitis that, from physical signs and the general bodily reaction, seem unusually acute and fulminating. In these patients the pulse is rapid and the volume impaired. Often there is other evidence of threatened circulatory failure. This condition is seen frequently in children. This group of patients undoubtedly will do better if operation is deferred until a conservative type of therapy can build up the general or local resistance. The so-called Ochsner type of conservative therapy has its ideal application in these patients. In many so treated, nature will ultimately reduce the surgery indicated to a simple incision and drainage of a localized abscess; usually the abscess points into the cul-de-sac and should be opened through the rectum or vagina.

If our policy of early operation is not increasing our mortality rate, then the pressing demand in some clinics for delayed operation has little justification. It is interesting to note that recently, in a comparable series of cases studied at the Leningrad Institute for Quick Aid in Russia,[15] the same conclusion was reached (Table 6). Further, early operation entails the factor of greater economy in the matter of prolonged hospitalization. The presence of long-standing intra-abdominal pathologic conditions, such as would follow delayed treatment, must lead to a greater number of intra-abdominal complications. The eventual drainage of intra-abdominal abscesses often results in ventral hernia.

TYPES OF INCISIONS

We have favored modifications of the McBurney incision in most instances. The exposure has been adequate and the convalescence shorter and smoother.

A right rectus incision provides very free and adequate exposure, but there is always the danger of disturbing a localized peritonitis and thus contaminating the entire abdominal cavity.

Objections to drainage through a rectus incision are those of sequelae such as evisceration, early and later intestinal obstruction, ventral hernia, etc. Since we have almost ceased to drain, our objections to the rectus incisions are less than formerly.

DRAINAGE IN PERITONITIS

For several years we have avoided all intra-abdominal drainage in peritonitis.[16] Perforated peptic ulcers, traumatic injuries of the gastrointestinal and genito-urinary tracts are closed without drainage. It is only in the chronic, well walled-off abscesses that we still use drains. The patients in this series who had drainage were those, for the most part, in the earlier years of our study before the general use of drains had been discarded. There is abundant clinical and laboratory evidence to show that drainage of the abdominal cavity in peritonitis is impossible and inadvisable for the following reasons:

(*a*) Within a very few hours the drain ceases to act other than as a foreign body which is walled off by adhesions of omentum, intestines and coagulum.

(*b*) The presence of a foreign body, such as a drain, has been shown to lower the natural immunity of the peritoneum against infection. (This would indicate that the drain is a menace rather than a help.)

(*c*) Drainage causes a temporary loss of the normal defensive peritoneal fluid.

(*d*) There is a longer and more stormy convalescence because of the added intra-abdominal pathologic changes caused by the foreign body, resulting in partial obstruction, ileus, and increased peritonitis.

(*e*) The incidence of infection in the wound is greater; an intra-abdominal drain through an infected wound attracts and harbors all the dependent suppuration of that abdominal wound. The profuse purulent discharge from such a drained wound arises primarily from suppuration

TABLE 7.—*Drainage*

	Intra-abdominal Complications (Pelvic Abscess; Ileus, Dynamic and Adynamic; Hemorrhage, Subphrenic Abscess, etc.		Pelvic Abscess Per Cent		Mortality Per Cent	
	Group II Gangrenous Nonperforated	Group III Gangrenous Perforated	Group II	Group III	Group II	Group III
Drained (121 cases)	19 per cent (of 32 cases)	37.7 per cent (of 89 cases)	9.3	15.3	9	10
Not drained (337 cases)	2.7 per cent (of 224 cases)	8.9 per cent (of 113 cases)	0	7.9	0.9	2.4

in the abdominal wall and not from within the abdominal cavity. The depth of such a drainage tract, therefore, collects suppuration from the abdominal wound and hence the intra-abdominal infection surrounding the drain is aggravated.

(*f*) There is a high incidence of early and late postoperative hernia.

(*g*) Necrosis from the pressure of the drain has been the cause of many fecal fistulae and fatal hemorrhages. (We have had only one case of fecal fistula in this series of one thousand cases of acute appendicitis, and it occurred in a case in which drainage was employed.)

(*h*) Drainage has increased the incidence of secondary intra-abdominal abscesses in our series (Table 7).

We wish to emphasize that this discussion regarding drains refers to intra-abdominal drains, and not to those which are placed in the abdominal wall down to the peritoneum. We feel that adequate drainage of a badly contaminated abdominal wound is very necessary.

CONCLUSIONS

1. An apparently increasing mortality rate from peritonitis needs very careful study with a view to the standardization of treatment in acute appendicitis.
2. We believe that immediate surgery, well done, will give the best ultimate results.
3. There is a very small group of patients whose general and local condition may contraindicate immediate surgery. This group is described.
4. The fallacy of delayed treatment is discussed.
5. The arguments against intra-abdominal drainage in peritonitis are stated.

TABLE 8.—*Mortality by Age Groups*

Age	Cases	Deaths	Mortality Percentage
0-9	83	5	7.9
10-19	327	5	1.5
20-29	307	5	1.6
30-39	134	7	5.2
40-49	83	6	8.2
50-59	36	4	11.1
60-69	19	4	21.0
70-79	3	0	0
80-plus	2	0	0
Total	1,000	36	3.6

DISCUSSION

CHARLES T. STURGEON, M. D. (1930 Wilshire Boulevard, Los Angeles).—Though we continue to write about acute appendicitis, expressing our views and methods of procedure, the mortality also continues to increase. Many factors are responsible for this increasing mortality:

1. Delay in seeking medical attention.
2. Incorrect diagnosis.
3. "Watchful waiting."
4. Inadequate preoperative preparation of the patient.

I feel that the greatest factor contributing to the mortality of appendicitis is the so-called "watchful waiting."

We have all been taught that as soon as the diagnosis of appendicitis has been made, an appendectomy should be performed immediately. Recently many papers have appeared wherein the author states that patients who have had symptoms of appendicitis for two or three days should be placed under observation; and many doctors, especially the younger men, have accepted this procedure as best applicable to the majority of cases of appendicitis.

In my opinion, "watchful waiting" should be applied only to cases with questionable diagnosis, and only after a careful history and examination has been made. The patient should be hospitalized and carefully observed and examined every two hours. As soon as the diagnosis is established, an appendectomy should be performed.

We all realize that patients presenting a generalized peritonitis do not come under the above classification. These patients require observation and preoperative preparation, and when a localized abscess is discovered, it should be drained.

We have stressed the point that the laity must be instructed in the fallacy of delay in consulting a physician, and as to the danger of administering cathartics to patients with abdominal pain. We should also reinstruct the medical profession that immediate surgery is still the treatment of appendicitis.

⁂

H. Glenn Bell, M. D. (University of California Hospital, San Francisco).—It is difficult to discuss a paper when one is in complete accord with the ideas expressed by the author. That is my position in regard to this article. For the past seven years I have followed the plan suggested by Doctor Rhodes and his co-authors, and the results have been very satisfactory.

In one of the tables of Doctor Rhodes' paper he has noted the operative mortality in representative and comparative series from different places. I am familiar with one of the large series cited, and know that in that series, even when treatment has not been delayed, drainage is used much more often than is our custom. Whether that is the entire reason for their higher mortality, it is rather difficult to say. It is reasonable to believe, however, that such drainage plays a tremendous part.

Discussion of isolated cases prove nothing. Only by a careful analysis of a thousand or more cases, such as Doctor Rhodes has made, can one hope to draw conclusions which will help the average surgeon in the more intelligent care of his patients.

In general, the mortality of acute appendicitis in this country is still too high. I am convinced that one reason for this is the feeling that acute appendicitis is a simple disease and that operation for it is simple to perform. Yet we know that appendectomy for acute appendicitis may be a most difficult operation and may tax the surgical skill and judgment of the best surgeon in the country.

⁂

Edwin M. Taylor, M. D. (230 Grand Avenue, Oakland).—It is a pleasure to have an opportunity to discuss some of the controversial points of Doctor Rhodes' paper on "Acute Appendicitis," namely:

When Is the Correct Time to Operate on "Late Cases."—This cannot be set from the beginning of the attack, as some authors attempt to do, but from the physical finding. It seems to me that the very desperately ill, toxic patient, with rapidly diffusing or already diffused peritonitis, has a better chance of recovery if operation is delayed and the so-called Oscher treatment is instituted. The other type of case in which I feel operation should be delayed, is the one with early beginning abscess formation, where there still remains some generalized peritonitis. In the latter type of case, usually in a week or ten days the localized abscess can be drained, and often the appendix removed, if readily accessible, with comparative safety.

Regarding Drains.—The profession in general are using less drains, but I cannot feel quite safe in closing up an abdomen in which the appendix has perforated. I cannot feel that a soft rubber drain is such a hazard in the abdomen. Maybe drains do not actually drain for many hours, but when placed in dependent points, as in the pelvis, in the right lateral gutter or beneath the terminal ileum, are there not sinus tracts formed, through which drainage would take place, should pus accumulate in these areas?

Type of Incision.—This is of paramount importance in treating acute appendicitis with or without peritonitis. The McBurney, or some modification of the lateral incision is certainly the incision of choice when the diagnosis of appendicitis is at all certain. Some large clinics have greatly decreased their mortality by almost universally adopting this type of incision without any change in their use of drains or methods of handling the cases.

Doctor Rhodes' results show a 3.6 per cent operative mortality, certainly lower than any reported from similar clinics.

THROMBOSIS AND EMBOLISM: PREOPERATIVE AND POSTOPERATIVE CARE IN THEIR PREVENTION *

By John H. Breyer, M.D.
Pasadena

Discussion *by E. Vincent Askey, M. D., Los Angeles; Willard J. Stone, M. D., Pasadena; H. Brodie Stephens, M. D., San Francisco.*

Massive pulmonary embolism has produced tragic and sudden deaths in the practice of every experienced surgeon. It is a postoperative disaster which every surgeon fears. Concerning fatal pulmonary embolism, statistics seem to show that it accounts for about 6 per cent of surgical deaths. One series, by Wharton and Pierson, reported that nearly half of the deaths after gynecologic operations were due to pulmonary embolism. Postoperative thrombophlebitis, which happens more frequently, prolongs hospitalization and often incapacitates the patient for months. Femoral thrombophlebitis, as reported by Albanus, occurred sixty-three times after 1,140 laparotomies, and forty-four of these cases resulted in embolism, of which ten patients died. A critical review of the literature is hereby attempted, hoping to develop some practical plan of prevention which might lessen the incidence.

FREQUENCY

Thrombosis and embolism are complications which occur in many diseases and conditions other than surgical and are, therefore, of general medical interest. They occur in the infectious diseases, as in influenza, pneumonia, tuberculosis, typhoid fever, and in sepsis. They occur in diseases in which the blood itself is altered, as in the anemias, leukemias, and in polycythemia; in cancer and in the degenerative diseases of the vascular system. American, as well as European literature, seems to indicate that the incidence of thrombosis and embolism has increased since the period of the World War. A report from the department of pathology of the University of Toronto, published in 1933, states that they have demonstrated pulmonary emboli in about 10 per cent of routine autopsies upon adults. They found it more common in medical than in surgical cases. In 6,581 necropsies performed in the city hospital at Kiel, Germany, reported in 1934, thrombosis was encountered in 14 per cent, and pulmonary embolism was observed in 9.7 per cent of the autopsies. From 1919 to 1928 the incidence of thrombosis cases had increased eight and one-half times the average for the years prior to 1919. Thrombosis occurred about equally in the two sexes, and was more frequent after forty-five years of age.

RELATION TO SURGICAL TRAUMA

As surgeons we are concerned whether trauma incident to the operation may be an activating factor in the production of thrombosis and embolism. Thrombosis is primarily a physiologic process, a defense mechanism, otherwise we would all die of hemorrhage. This defense mechanism comes into action when injury to the blood vessels and tissues takes place. Its initiation appears to be through the action of some vital substance or substances called forth by the injury, which are variously known as fibrin ferment, thromboplastin and thrombokinase, in the formation of which the leukocytes, blood platelets, calcium salts, and tissue extracts play an important rôle. Normally, clot formation takes place sufficient to plug the severed vessels, and then ceases. Why it ceases is as great a mystery as why it starts. When clot formation exceeds its normal required limits and extends into the stream of circulating blood, it becomes the pathologic process of thrombosis. The restraining limiting factors are no longer acting; why, we do not know. Natural control of the tendency to thrombosis may again be reëstablished, holding the tendency in abeyance either permanently or for a time. When again brought under control absorption, organization, endothelialization and canalization of the thrombus may take place.

---

* Read before the General Surgery Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

CONTRIBUTING CAUSATIVE FACTORS OF PATHOLOGIC THROMBOSIS

The most widely accepted contributing factors in the causation of pathologic thrombosis are: (1) slowing of the circulation; (2) changes in the vessel wall due either to trauma or infection; and (3) alterations in the composition of the blood itself. It is now generally recognized that the exciting cause is not one factor alone, but that an interaction of two or more factors is probably necessary for the development of thrombosis.

Slowing of the Circulation. — Slowing of the circulation is probably the most important cause in the development of thrombosis. Thrombosis forms rarely in the heart and arteries, but is comparatively common in the veins. It is rare in the young with efficient circulation, but becomes more frequent in advancing age with degenerative changes in the cardiovascular system, which may result in slowing of the blood stream with lowering of the blood pressure. Thrombosis occurs quite frequently during life in the prostatic plexus of veins. Almost any adult male past middle life has calcified phleboliths in this plexus of veins as a result of previous formation of thrombi, and at death, from any cause, this plexus is likely to be distended with antemortem clots. In the female the cervical and vaginal plexuses may be similarly affected, though less frequently so. A saccular aneurysm is usually more or less filled by a thrombus. It is believed that this is due to the simple stasis or stagnation of the circulating blood at these particular locations. As pointed out by Welch, the slowing and eddying of the circulation causes the platelets to agglutinate along the vessel wall to form a homogeneous layer. Following this there is a settling out of white blood corpuscles, after which fibrin begins to form at the margins of the clot. The vessels most often involved in this type of bland thrombosis are the large veins of the extremities and pelvis, especially the femoral and iliac veins.

Changes in the Vessel Walls.—That changes in the vessel walls due to either trauma or infection may lead to thrombus formation at the site of injury has long been recognized. A thrombosis may develop, however, at a location distant from the injury site and away from the source of infection. Whether a phlebitis is primary, with secondary infection of the thrombus, or vice versa, is difficult to prove. Postoperative and puerperal phlebitides are usually explained as due to infection, being more common in patients in whom infection is present. However, a direct avenue of infection cannot always be demonstrated. Infections no doubt add to the general impairment which increases the tendency to vein complications. Many authors believe that the toxins from infection, necrotic processes, and from tissue damage are probably important contributing factors in promoting thrombosis. The vein reaction to the formation of the thrombus may be a nonbacterial reparative inflammation of the mildest form, or may be of the acutely inflammatory and suppurative type. The thrombus may be but loosely attached to the vein wall or may be firmly attached as a result of the inflammatory reaction.

Alterations in the Composition of the Blood.—Changes in composition of the blood have frequently been described as favoring the development of thrombosis. It is variously attributed to increased friability of the platelets, to increase in their number, to shortening of coagulation time, increased viscosity, accelerated sedimentation rate, dehydration, the augmentation of the clotting factors, and other changes. These are changes which cannot readily be measured, and these elements probably play no rôle in the initiation of the thrombus, but may influence the secondary coagulative phase affecting the propagation of the peripheral portions of the thrombus.

EMBOLI

An embolus, of course, is a solid, oily or gaseous mass in the free blood stream. The danger of thrombo-embolism is inversely proportionate to the amount of vein inflammation accompanying the thrombus. The pathology produced depends on the size of the embolus, its septic or aseptic character, and the size and location of the occluded artery. In pulmonary embolism the right lung is more often involved than the left, and the lower lobes more frequently than other parts of the lung. In order to be of size to obstruct one or more of the main branches of the pulmonary artery, the embolus must take origin from a major vein, which has been shown by autopsy studies in 85 per cent of cases to be usually the femoral or iliac veins. Under such conditions pulmonary edema follows, with death taking place in a few minutes, or within several hours in all but exceptional cases. Fifty per cent die within fifteen minutes.

Moderate-size emboli pass the main pulmonary artery and occlude smaller branches, resulting in pulmonary infarcts. A hemorrhagic consolidation of the infarcted lung or lobe follows, particularly if there is a coexistent respiratory or cardiac impairment. Such infarcts are said to produce a mortality of 12 to 15 per cent. Many of the smaller-size emboli produce no detectable clinical disturbance, and occur more frequently than is generally supposed. Septic infarcts may result in empyema, pneumonitis or lung abscess. However, the infrequency of infection in pulmonary infarction is offered as evidence of the nonbacterial origin of the thrombus.

CLINICAL OBSERVATIONS ON THROMBOSIS AND EMBOLISM

The following clinical details are of interest in their relation to thrombosis and embolism. Postoperative massive fatal embolism is liable to occur during the convalescent period, usually during the second week, without swelling of the legs or evidence of thrombophlebitis, or any clinical signs which would attract the attention of the surgeon to the likelihood of its occurrence. The majority of the patients are between forty and seventy years of age, and obesity seems to be a predisposing factor. The presence of cardiovascular degenerative changes and carcinoma have been noted in a high percentage of cases. The type of anesthetic used appears to have no bearing on the occurrence of this unfortunate accident which seems to follow abdominal and pelvic operations in about 70 per cent of cases. Fatal embolism most frequently follows stomach surgery, especially for cancer; pelvic surgery, especially for fibroids of the uterus; and operations for prostatic hypertrophy. Gall-bladder surgery, operations on the large intestine, appendectomies and even hernia operations may be followed by this complication. Thyroid surgery is particularly free from postoperative thrombosis and embolism. Thrombophlebitis of the superficial veins of the extremities usually does not result in large emboli, but repeated small infarcts, however, may result from dislodged fragments of the advancing type of phlebitis. When inflammation and thrombosis involve the deep veins of the extremities, it gives the operator concern. Whether such a thrombophlebitis is the suppurative or nonsuppurative type, the formation of an embolus is always a possibility.

PROPHYLAXIS: PREOPERATIVE MEASURES

It has been said, "there is a probability that the tendency to thrombosis may depend upon the patient's physical condition rather than that he has undergone an operation, but it is equally probable that had he not had the operation the thrombosis would not have developed." Prophylaxis against thrombosis and embolism rests largely upon the care with which we estimate our surgical risks, and the preoperative preparation of such impaired cases. This is especially important since the trend is to offer surgery to elderly patients even with late-stage pathology. Preventive treatment aims at (1) prevention of thrombosis and (2) the adequate treatment of manifest thrombosis. The factors responsible for thrombosis have been enumerated. It probably requires the interaction of several factors in the majority of cases, yet some develop thrombosis with a minimum of the contributing factors, and others with the maximum number may escape this complication. The patient should be put in the best possible physical condition and made the best physiologic risk possible under the circumstances. A careful chest examination by an internist should be part of the preoperative routine. Definitely known foci of infection of teeth, tonsils, prostate or cervix should be considered in their possible relation to the inevitable hazard which accompanies any operative procedure. Only the acute surgical emergencies should be operated in the presence of "head colds." The appropriate cardiovascular stimulants should be used when evidence of myocardiac insufficiency is present, such as increased pulse rate with falling blood pressure. Digitalis, a drug much misused by surgeons, is often not only useless, but harmful. The use of digitalis in adequate dosage should be restricted to cardiac insufficiency or decompensation, and especially to disturbances of rhythm such as auricular fibrillation, in which a rapid irregular heart rate is accompanied by a pulse deficit. Slowing of the heart rate in auricular fibrillation as a result of the administration of digitalis is beneficial. The administration of digitalis is of doubtful utility to slow the heart rate in toxic or septic conditions. The use of caffein or the theobromin or theophyllin salts for their general circulatory effects are much more frequently indicated when cardiac stimulation is believed necessary. The body fluids should be increased and maintained by blood transfusions, salt and glucose solutions before, during and after operation. Secondary anemia, if present, should be improved by the various methods available. Starving a patient before operation should be avoided, and when the diet is restricted for any reason the giving of glucose solution is indicated. The work of Mills, Bancroft, and Stanley Brown have demonstrated an increased coagulability of the blood following a high protein diet, while a diet adequate in carbohydrates and fat was not followed by such an effect. It thus seems advisable to place all patients on a low protein diet for the first two weeks following operations within the abdomen or pelvis, in cases of trauma with much tissue mutilation and in cases of phlebitis at all times. Care should be taken to avoid chilling of the patient, before, during, and after operation. The legs and feet must be kept warm, and the local use of heat may be indicated.

Atraumatic surgery is the ideal toward which all surgeons strive. Hemorrhage and shock have a profound influence on venous stasis. The patient's position on the operating table should be made as comfortable as possible, avoiding pressure anywhere which might promote venous stasis, especially in the legs. Harsh and prolonged retraction should not be used and injury to the deep epigastric veins is to be avoided, as thrombosis may start in these vessels. It is better to ligate and divide than to injure veins by puncture, bruising, or overstretching. Mass ligatures are to be avoided, and sutures penetrating veins should be removed and reapplied. Septic wounds should be thoroughly drained to avoid the spread and absorption of septic products.

POSTOPERATIVE MEASURES

During the postoperative stage nothing should be done which promotes venous stasis, such as use of tight abdominal dressings and binders. When gas distention takes place a binder may become too tight. Due to vomiting and diaphoresis the body fluids may become greatly depleted, which necessitates the use of transfusion of blood, salt and glucose solution. Frequent moving and turning of the patient is indicated. The pain produced by the incision may inhibit the normal respiratory excursion; therefore, encourage deep breathing, as the diaphragm is a circulatory as well as a respiratory organ. The inhalation of carbon dioxid at intervals may be indicated. Moderate elevation of the foot of the bed, provided there are no contraindications, during the first twenty-four hours after operation, when activity is at a minimum, might act as a prophylactic measure favoring return venous flow. It is important to frequently check the blood pressure in order to determine whether the pressure normal for the patient is being maintained. Methods to increase body metabolism may be indicated. Doctor Walters gives two grains of desiccated thyroid gland extract three times a day in all cases except those with increased pulse rate and temperature. The medication is begun two to four days after operation and continued until usually the tenth day. If the pulse and temperature are increased, the use of thyroid extract is discontinued. In the series in which thyroid extract was used the incidence of embolism was reduced to .09 per cent. However, all other known methods of improving the circulation were also instituted. As an effective means in reducing the incidence of thrombosis and embolism some surgeons favor early mobilization of surgical patients. Other surgeons believe that this is done at the expense of wound repair. The adoption of systematic light active and passive exercises provides almost all the advantages gained by a shortened stay in bed without interfering with wound repair. These exercises stimulate peripheral circulation, and add much to the comfort and strength of the patient. Meticulous attention to details and close observation that they are carried out is essential.

When thrombosis of the veins of the legs does occur, statistics show that the results are not frequently fatal. Every case must be decided on its own merits. Thrombosis should be suspected when a low elevation of temperature in a clean surgical case takes place, with increased pulse rate with pain in leg or foot, and with increased size of leg as determined by a tape measure. The greatest possible caution is called for to prevent dislodging emboli. This necessitates the gentlest possible handling during nursing care, particularly during the bath and in the use of the bed pan. The leg should be kept elevated on a pillow to keep it warm, and to avoid pressure of the bed clothes. Whatever seemed necessary in the prevention of thrombosis is now reversed for the prevention of embolism. The guiding principle is rest until the thrombus has been anchored by organization. Occurrence of pleuritic pains in the postoperative period should be considered the result of infarction and not a "dry pleurisy," and proper precautions should be instituted.

IN CONCLUSION

The important thing is to recognize the possibility, and even probability, of the development of thrombosis or embolism, and to endeavor to find some practical method for actively combating their development. To recognize a complication at an early stage makes treatment more effective.

701 Professional Building.

DISCUSSION

E. Vincent Askey, M. D. (1930 Wilshire Boulevard, Los Angeles).—Doctor Breyer has summed up very capably the problem which confronts us. He has called to our attention work which has been done on this subject. He has adequately discussed those factors involved in the physical forces predisposing to thrombosis, namely, trauma, infection, stasis or slowing of the circulation, and dehydration.

However, if I understood him correctly, he stated that changes in blood composition cannot be measured readily and that these elements probably play no part in the initiation of a thrombus, but only with the propagation of a thrombus already started. This, I think, is not strictly so, and we differ in this opinion. There have been methods suggested to warn us of impending thrombosis and definite treatments proposed to combat it.

It is probable that in the future more attention will be paid to the biochemical changes found in the blood itself in thrombosis and embolism.

Bancroft and Stanley-Brown have suggested an index of clotting potentiality. This index can be determined in any well-equipped hospital laboratory. They believe it is of as great value in denoting impending thrombosis as is a leukocyte count in an infection. In cases showing a high index of clotting potentiality they advise the repeated use of 10 per cent solution of sodium thiosulphate intravenously. They believe their results show definite value. The effectiveness of the sodium thiosulphate they explain as follows:

In the body tissues there is an oxidation enzyme called glucothione—a sulphur compound. Its action is to lessen the development of lactic acid. Lactic acid results from injury to tissues. Sodium thiosulphate supplies sulphur, which increases the content of glucothione either by neutralization of the lactic acid or by the formation of new glucothione.

Howell has prepared, from dogs' livers, an anticoagulant called Heparin and has used it in thrombosis cases with good results. Rowntree, however, warns us that as yet preparations available are not pure enough to be used without danger.

Recently De Takats has called attention to the marked amelioration of symptoms in cases of frank embolism by the use of papaverine. This drug relieves surrounding vasoconstriction and spasm, and encourages early collateral circulation.

The problem is as yet unsolved. Thrombosis and embolism as postoperative complications constitute a fearsome tragedy in the practice of any surgeon.

Willard J. Stone, M. D. (65 North Madison Avenue, Pasadena). — Every physician who has witnessed the sudden and, in many instances, unexpected death of a patient from pulmonary embolism during convalescence from a surgical operation, will appreciate Doctor Breyer's thoughtful review of the methods which may be used to prevent such a tragic accident.

From the medical standpoint, the circulatory condition of obese patients with slow heart rates and subnormal metabolism may be improved by the administration of thyroid extract during the first ten days of convalescence. Likewise the administration of glycocoll, for its general stimulating action on metabolism, leading to improved circulatory efficiency, may be helpful. The routine use of digitalis during convalescence whenever the heart rate is increased as a result of surgical shock, is difficult to justify from a pharmacologic standpoint. Its use should be limited, as Doctor Breyer has emphasized, to the treatment of auricular fibrillation and cardiac decompensation. With other forms of cardiac insufficiency, especially if the heart rate is slowed, the administration of theobromin or theophyllin salts may be beneficial. Strychnin as a circulatory tonic has gradually become less popular because of the insufficient dosage commonly employed. For patients with slow heart rates who may be believed to be unusually susceptible to thrombotic tendencies, the dosage should approximate one-tenth grain four times daily.

⁂

H. Brodie Stephens, M. D. (384 Post Street, San Francisco).—Doctor Breyer has presented an excellent review of the distressing complication of postoperative thrombosis and embolism. The author in his review rightly emphasizes the frequency of this complication and, because of its frequency, a discussion of the subject is timely.

A careful study and adherence to the principles laid down by Doctor Breyer will undoubtedly frequently prevent this complication; or, if thrombosis does occur, its seriousness will be lessened by adopting the general principles set up by the author.

Notwithstanding the thoroughness of this paper, all will agree, I believe, that there will be still many cases of postoperative thrombosis and even embolism, in spite of whatever we do before or after operation. It appears to me that we have far from solved the problem, and much experimentation and clinical investigation are still needed, if we are to thoroughly understand and prevent this complication so far as it concerns the surgical patient.

Pulmonary embolism has been satisfactorily handled by immediate operation, but it requires a well-trained house staff and a sterile set-up for such an emergency. We have felt this to be a worthwhile routine, and the house staffs are each year given instruction in how to handle this emergency.

⁂

Doctor Breyer (Closing).—I appreciate the suggestions made by the discussers and the emphasis placed on certain phases of the subject, which I could not stress due to the shortness of the paper. The underlying surgical principle of the recommended exercises in the prevention of thrombosis is the effect of muscle action on the venous circulation. We all have made use of this principle, when we ask the donor for a blood transfusion, to open and shut his hand after the trochar needle has been inserted in the median basilic vein.

Dr. Alvin G. Foord, pathologist at our Huntington Memorial Hospital, has stated to me that when the autopsy surgeon of the pathologic service of Dr. Julius Erdheim of Vienna failed to find the source of the pulmonary embolism, Doctor Erdheim would ask if the veins of the calves of the legs had been dissected out and explored. Very often when this was done, the origin of the embolus was found to be there.

Exercises that will cause tensing of the flexors and extensors of the foot, and of the tensor femoris muscle, will produce the desired effect.

WHOOPING COUGH: ITS PROPHYLAXIS AND TREATMENT*

By J. M. Frawley, M.D.
Fresno

Discussion *by A. J. Scott, M. D., Los Angeles; Francis Scott Smyth, M. D., San Francisco; Charlotte Singer Brooks, M. D., San Francisco; Edward B. Shaw, M. D., San Francisco.*

A PROGRAM directed toward the control of whooping cough has been carried on since 1932 in the public schools of Fresno. Two methods have been employed, viz., isolation and vaccination.

ISOLATION

In order to be of benefit as a factor in controlling the spread of whooping cough in the classroom, isolation has to begin at the onset of the cough. This is possible only when the cough-plate method [1] is used to detect early cases.

At the outset of this study, cough plates were made for us by Doctor Krueger at the bacteriological department of the University of California in Berkeley. They were always received in perfect condition, and the exposed plates were returned by mail after incubating overnight. During one school season they were sent to us by Doctor Kellogg from the State Department of Public Health Laboratories in Berkeley, but two years ago a cough-plate station was organized at the Fresno County Hospital, and the plates have been made and read there. They are prepared according to a method recommended by J. J. Miller.

TECHNIQUE

The technique is described in detail by Kendrick, Miller, and Lawson [2] in the American Public Health Association Year Book for 1935-1936:

> A modification of Bordet and Gengou's potato blood agar is made as follows:
>
> Base:
> Peeled sliced potatoes, 500 mg.
> Glycerin, U. S. P., 40 cc.
> Distilled water, 1,000 cc.
>
> Boil the potatoes in glycerin and water until soft. Make up to volume, strain through gauze and allow to stand for sedimentation. Siphon off the supernatant liquid.
>
> To 500 cubic centimeters of clear potato extract add:
> Sodium chlorid solution, 0.75 per cent, 1,500 cc.
> Agar, Bacto, 60 gm.
> Proteose Peptone, 20 gm.
>
> Let stand for fifteen minutes, to saturate the agar. Heat until the agar is dissolved, and dispense in amounts convenient for storage. Autoclave for twenty-five minutes at fifteen pounds pressure (120 degrees centigrade). This base may be stored indefinitely.
>
> Finished medium—To the melted base, at 45 degrees centigrade, add blood to make a final concentration of at least 15 per cent. The blood should be used when fresh, never more than seventy-two hours after it has been obtained. It may be from sheep, horse, or human source, but avoidance of horse blood for the vaccine medium is recommended. Mix the blood with the base by whirling, and pour into plates—about 15 cubic centimeters per Petri plate. Either glass plates or metal boxes may be used.

The potato extract-glycerin-agar base is kept stored in the ice-box, and sufficient Petri plates for a week's supply are made up by adding blood obtained from hypertension cases or from human placentas. The plates are kept in the ice-box until needed.

---

* Read before the Pediatric Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

The detection of early cases rests with the school nurse. She must be on the lookout for suspects among the children, who are referred to her each morning by the teachers, and should take cough-plate cultures in all cases where there is any cough, especially in the case of children who are known to have been exposed to whooping cough.

The plate is uncovered and held five or six inches from the child's mouth. Gentle pressure over the trachea just below the larynx will elicit coughing, and after several good expulsive coughs the plate is covered and taken immediately to the incubator. In positive plates the characteristic tiny colorless hemispherical colonies appear, surrounded by a zone of hemolysis. The organisms are described as follows:[2]

> Stained by Gram's method, B. pertussis decolorizes readily—much more readily, in fact, than does H. influenzae. Viewed microscopically, the small, faintly stained coccoid bacilli are scattered evenly throughout the film, occurring singly for the most part, seldom in chains of even two, and not found as pleomorphic threads. Frequently they show bipolar staining.

It takes forty-eight to seventy-two hours for the colonies to develop, and during that time a clinically suspicious case, or one with a history of exposure, must be treated as if positive. It is essential for the school nurse to have not only the coöperation of the teachers, but she must also have the good will of the practicing physician in the community. We have had splendid coöperation on the part of the physicians, and are occasionally called on to furnish cough plates to physicians for use in their private cases.

HOW STATE SUBSIDY FOR SCHOOL ATTENDANCE WORKS OUT

One of the chief obstacles to excluding children with incipient whooping cough lies in the system of granting state aid to schools, based on average daily attendance. Recently a school in Fresno County was closed down completely for a month. So many children were absent with whooping cough that the trustees decided it would be better to close the school than to allow the attendance to fall below a certain level. By keeping the school open with the decreased attendance they would have lost $1,200 of next year's state grant.

This program of early isolation is not new. In Denmark, children are excluded from school during the early catarrhal stage, and allowed to return after the paroxysmal stage has been well established after the cough plates are consistently negative.

Besides the use of cough plates for diagnosis, a second measure which has been tried out in the Fresno public schools, has been prophylactic vaccination of kindergarten children. The opportunity is offered to each new class, and the vaccine given on the written request of the parent.

VACCINATION

The attitude toward vaccine as a prophylactic and therapeutic agent in whooping cough has undergone a radical change within the past few years. The year 1931 seems to have been the turning point. In that year Leslie and Gardner[3] published in the *Journal of Hygiene* their classical study on the phases of hemophilus pertussis. Previously, most of the vaccines used were entirely innocent of antigenic principle.[4]

However, in looking back over the earlier period, the work of Madsen[5] and his coworkers at the Danish Serum Institute stands out as peculiarly in line with the later idea.

Greatly renewed interest in whooping cough research followed the appearance of Leslie and Gardner's work.

Sauer,[6] in 1933, published his successful results of prophylactic vaccination using very large doses of unwashed Phase I organisms grown on human blood enriched by Bordet medium. He has taken the stand that vaccination is effective only when given as a preventive, and not as a curative measure. In his latest review[7] of his own cases, published in the *American Journal of Public Health,* November, 1935, he says:

> Bacillus pertussis vaccine, like typhoid vaccine, is an immunizing, not a curative, agent. A time interval of several months is required for immunization to be complete. About 10 per cent of the children injected with a total of 8 cubic centimeters of the approved commercial vaccine contracted pertussis when subsequently exposed to infection.

Doctor Park,[8] at the meeting of the American Academy of Pediatrics in June, 1935, reported the result of an extensive investigation into the value of prophylactic vaccination carried out by the New York City Health Department with Mishulow's vaccine. This vaccine is made from Phase I organisms grown on sheep's blood agar, with one per cent of sheep-serum broth added on the surface of the medium after inoculation. Vaccines grown in this manner contain, in addition to the pertussis bacilli, a toxic substance which increases the stimulation of agglutinins. Doctor Park concluded that

> The efficacy of pertussis prophylactic vaccination appears to depend primarily upon sufficient dosage.
>
> A group of thirty-eight children were given seventy-seven to eighty-eight billion of the N. Y. C. Vaccine. Five of these were exposed to active cases, and none developed pertussis. Another group of 148 children were given thirty to seventy-five billion of the same vaccine; sixteen of them were exposed and nine developed pertussis, but four of these nine had no whoop, did not vomit, and the cough lasted only two or three weeks. They were so atypical that they could not have been diagnosed as cases of pertussis if they had not been definitely exposed. As the dosage decreased, the incidence became higher.

Kendrick and Eldering[9] in January, 1936, reviewed the work on the prophylaxis of whooping cough being carried on by the Michigan Department of Health. Doctor Kendrick has used a vaccine which is a once-washed ten thousand million per cubic centimeter suspension of B. pertussis, Phase I of Leslie and Gardner, grown on Bordet-Gengou medium enriched with 15 per cent sheep's blood. The organisms are killed with merthiolate 1:10,000 or phenol 0.5 per cent allowed to act at cold-room temperature for a week or more.

A total dosage of 7 cubic centimeters is given, divided into four doses. Out of a large number of vaccinated children, follow-up work has indi-

TABLE 1.—*Summary of Prophylactic Vaccination With Krueger's Pertussis U. B. A. (Commercial)*

Dosage	Number of Children Vaccinated	Exposures		Developed Whooping Cough		Percentage of Failures
8.0 cc.	505	Home	30	Mild	33	
		School	68	Moderate	6	
				Severe	4	
		Total	98	Total	43	44.0%
12.0 cc.	113	Home	9	Mild	6	
		School	12	Moderate	1	
				Severe	3	
		Total	21	Total	10	47.6%

cated that of ninety-five who were subsequently exposed, thirteen (13.6 per cent) developed whooping cough. Of these, nine cases (9.2 per cent) were light or very light.

In an unvaccinated control group there were 128 exposures with 98 (88.2 per cent) cases of whooping cough. Of the ninety-eight cases, nineteen, or 19.3 per cent, were light or very light.

To review, briefly, the Michigan Department of Health reports that, after vaccination, 13.6 per cent of exposed children have developed whooping cough, while Sauer reports about 10 per cent of exposures among his vaccinated cases have developed whooping cough.

FRESNO PROCEDURE

In the vaccination program at Fresno, Krueger's Pertussis U. B. A.[10] has been used. This vaccine* is a solution of endocellular antigen extracted from washed Phase I H. pertussis organisms by mechanical disruption and ultrafiltration.

By this method of preparation, including the thorough washing of the bacterial cells, the toxic filtrate which gives the reaction of Schwartzmann has been discarded with the washings. In a personal communication Doctor Krueger says that:

> Bacterial filtrates have long been known to contain antigenic fractions and to be capable of inducing toxic reactions under certain conditions. It is also true that broth filtrates regularly contain nonspecific and irritating metabolites. I feel that one might well sacrifice some of the antigenic fraction present in the filtrate, in order to avoid nonspecific reactions. That the specific antigen resides in the cell itself is evidenced by the work of Miller, Browne, and McCrea,[11] who showed that the U. B. A. produces complement-fixing antibodies against H. pertussis when injected into rabbits. Similarly, complement-fixing antibodies were produced in children as well as agglutinins and precipitins in some instances, and by Miller and Browne,[12] who were successful in sensitizing guinea pigs with Phase I H. pertussis cultures, so that the classical Schultz-Dale reaction was obtained with pertussis U. B. A.

The first clinical reports [13] published on pertussis undenatured bacterial antigen were promising. The antigen solution used was prepared in Doctor Krueger's laboratory, and the organisms used were recently isolated during a current epidemic and were grown on media enriched with human blood. The commercial product has been modified to some extent, in so far as sheep's blood is used in the culture medium.

This commercial product has been used in a sufficiently large number of cases to justify an evaluation at this time. It has been used as a prophylactic agent before exposure, in prophylaxis after exposure, and therapeutically after coughing has begun.

PROPHYLAXIS BEFORE EXPOSURE

During the last two school years Pertussis U. B. A.* was given as a prophylactic agent before exposure to two groups totaling 618 children. Some 505 children received 8 cubic centimeters, 113 received 12 cubic centimeters. Children in these groups who were subsequently exposed contracted whooping cough in a high percentage of cases, as shown in Table 1.

It must be concluded that in the dosage used, H. Pertussis U. B. A. failed to protect a sufficient percentage. However, as Doctor Park has pointed out, the efficacy of prophylactic vaccination depends primarily on sufficient dosage. The present commercial material contains only 10 milligrams of protein nitrogen per 100 cubic centimeters of antigen solution. It remains to be seen whether protection can be offered when adequate dosage is employed. In order to achieve this result, some means may have to be found of supplying the material in far greater protein nitrogen concentration.

PROPHYLAXIS AFTER EXPOSURE

The published reports on the use of Pertussis U. B. A. as a prophylactic agent after exposure have been summarized by J. J. Miller in a report on H. Pertussis U. B. A. (Krueger) given before the Laboratory Section of the American Public Health Association at Milwaukee, October, 1935. The vaccine he reported was used during the incubation period in ninety-eight cases; 50 per cent developed a cough which, in most cases, was mild or atypical.

This attack rate of 50 per cent of exposures compares favorably with an attack rate of 76.5 per cent of exposures in a group of unvaccinated children observed by Kendrick.[11]

It would seem from the published reports that considerable benefit followed the administration of Pertussis U. B. A. during the period of incubation. The chief objection to its use lies in the large number of daily injections that are required.

THE USE OF PERTUSSIS U. B. A. IN TREATMENT

The use of vaccine in the treatment of whooping cough is based on the fact that the disease is one of prolonged duration, usually taking six to eight weeks for immunity to develop. In such a slowly progressing infection it is rational to attempt to hasten the development of immunity by artificial stimulation of antibody formation.

---

* The vaccine was furnished by the Eli Lilly Company.

Table 2.—*Summary of Treatment With Krueger's Pertussis U. B. A. (Commercial)*

Case Age	Treatment Began	Duration Treatment in Days	Dosage	Duration of Symptoms After Treatment Began
1 H. W. 2 years	Five days before onset of symptoms	7	57 cc.	Mild cough for one week.
2 B. K. 8 weeks	Three days before onset of symptoms	8	12 cc.	Severe coughing for one week.
3 B. B. 6 years	Two days before onset of symptoms	8	60 cc.	Mild atypical cough for eight days.
4 B. B. 13 months	Two days before onset of symptoms	13	85 cc.	Mild cough for two weeks. Whooped for three days.
5 S. H. 3 years	Coughing two days	10	27 cc.	Whooped very little for one week.
6 R. W. 2½ years	Coughing two days	6	60 cc.	Mild atypical cough for one week.
7 M. B. 3½ years	Coughing two days	4	20 cc.	Coughed for four days. Six days later took cold; whooped and vomited three days.
8 D. A. 17 months	Coughing two days	5	47 cc.	Mild cough for one week.
9 R. H. 18 months	Coughing two days	5	40 cc.	Cough lasted for three days. Whooped three times.
10 D. R. 2 years	Coughing three days	7	57 cc.	Coughed for one week.
11 C. S. 5 years	Coughing three days	7	33 cc.	Coughed for nine days. Whooped four days, vomited once.
12 B. A. 6 years	Coughing five days	6	48 cc.	Coughed for eight days. Whooped four days, vomited once.
13 C. A. 3½ years	Coughing five days	7	53 cc.	Coughed for eleven days. Whooped five days.
14 E. H. 2½ years	Coughing six days Whooping and vomiting one day	4	33 cc.	Coughed five days. Whooped and vomited three days.
15 B. P. 10 months	Coughing one week	5	10 cc.	Coughed four days.
16 T. F. 20 months	Coughing one week	9	43 cc.	Coughed ten days. Whooped and vomited three days.
17 L. H. 6 years	Coughing eight days	10	48 cc.	Coughed for twelve days. Whooped two days.
18 D. B. 3½ years	Coughing eight days Whooping two days	17	122 cc.	Coughed three weeks. Whooped and vomited severe eighteen days.
19 H. C. 2 months	Coughing ten days	9	14 cc.	Coughed for nine days.
20 A. J. 3 years	Coughing ten days Vomiting three days	11	40 cc.	Twelve days more of whooping and vomiting.
21 A. J. 7½ years	Coughing ten days Vomited once	6	23 cc.	Coughed for six days. Whooped two days.
22 M. H. 4½ years	Coughing ten days	7	53 cc.	Coughed for seven days. Whooped three days.
23 G. E. 8 years	Coughing eleven days	7	60 cc.	Coughed for seven days. Whooped two days.
24 G. E. 5 years	Coughing eleven days	7	60 cc.	Coughed for seven days.
25 P. L. 5 months	Coughing eleven days.	6	28 cc.	Coughed for five days. Two weeks later took cold, whooped and vomited three nights.
26 J. B. Adult	Coughing thirteen days.	5	36 cc.	Coughed for six days. Whooped and vomited for two days.
27 B. H. 1 year	Coughing thirteen days.	9	41 cc.	Coughed for thirteen days. Whooped five days, vomited one day.
28 R. Z. 3½ years	Coughing two weeks Whooping and vomiting four days	5	25 cc.	Coughed for six days. Whooped three days, vomited two days.
29 D. B. 10 months	Coughing two weeks Whooping and vomiting three days	9	68 cc.	Coughed for ten days. Whooped four days.
30 A. S. 3 years	Coughing two weeks	7	29 cc.	Coughed for nine days. Whooped five days, vomited four days.

(Continued on next page)

Table 2.—*Summary of Treatment With Krueger's U. B. A. (Commercial) (Continued)*

31 N. A. 3 years	Coughing two weeks Whooping and vomiting two days	11	78 cc.	Eleventh day of treatment stopped vaccine because of reaction. Whooping and vomiting for seventeen days.
Case Age	Treatment Began	Duration Treatment in Days	Dosage	Duration of Symptoms After Treatment Begun
32 S. P. 3 years	Coughing two weeks	5	14 cc.	Coughed for nine days.
33 F. G. 3½ years	Coughing two weeks Whooping and vomiting two days	5	19 cc.	Coughed one week. Whooped and vomited three days.
34 J. C. 6 years	Whooping and vomiting for two weeks	18	54 cc.	Coughed for three weeks. Whooped and vomited fourteen days.
35 J. W. 5 years	Coughing eighteen days Whooping ten days	8	80 cc.	Coughed for nine days. Whooped for seven days.
36 P. Mc. 18 months	Coughing eighteen days Severe whooping and vomiting three days	9	43 cc.	Coughed for ten days Whooped and vomited six days.
37 D. Mc. 4 years	Coughing three weeks Severe whooping and vomiting	10	68 cc.	Coughed, whooped and vomited for ten days more.
38 B. W. 2 years	Coughing three weeks Severe whooping and vomiting one week	5	25 cc.	Coughed for six days. Whooped and vomited three days.
39 T. P. 5 years	Severe coughing six weeks, whooping and vomiting two weeks	5	23 cc.	Stopped whooping and vomiting in five days.

The logical agent to bring about this objective would be a lysed vaccine. In such a vaccine there is a minimum of alteration of the antigenic properties, and the antibody stimulation begins at once without any preliminary period being required for the liberation of the antigen by bacteriolysis. Krueger's pertussis antigen is a vaccine of this type and, theoretically, meets all requirements. In practical use it has received considerable favorable attention.

To a recent questionnaire, replies were received from 162 pediatricians who had used Pertussis U. B. A. in the treatment of over 3,700 cases of whooping cough, and 104 (63 per cent) reported favorably.

However, in these cases no controls were used; and in a disease so variable in duration and severity as whooping cough, adequate controls, while difficult to obtain, are necessary.

Recently, I have had the opportunity to use the antigen in treatment in a small series of approximately forty cases, using as controls an equal number of cases observed simultaneously in the same schoolrooms, although obviously not from the same families. Large doses were given subcutaneously, 5 cubic centimeters daily or twice daily to children over one year of age, 2 to 5 cubic centimeters to children less than one year. Daily records were kept in both series on the number of coughing spells each night, the number of vomiting attacks, etc.

CONCLUSIONS

While this series is too small to form the basis of any definite conclusions, nevertheless it would seem that, in some cases at least, a modifying influence was exerted. The average duration of coughing for all children receiving daily vaccine injections was 2.7 weeks, with an average paroxysmal stage of 1.2 weeks. In the control group, the average duration of coughing was 6.5 weeks, with whooping and vomiting for 2.7 weeks.

The best results were obtained when injections were begun either during the incubation period or on the first day or two of coughing, or else in the late stages after the disease had passed its peak. There was no certainty about the influence which could be expected when injections were begun during the height of the infection.

SUMMARY

1. Krueger's Pertussis undenatured bacterial antigen (commercial) was used as a prophylactic agent in two groups of children, totaling 618. Protection against whooping cough was found to be insufficient to justify its use in prophylaxis before exposure.

2. In prophylaxis after exposure, and in treatment of early cases of whooping cough, modification of the expected course of the infection followed the administration of large daily doses of antigen. The average duration of coughing in thirty-nine children given injections was 2.7 weeks, with a paroxysmal stage of 1.2 weeks; in an equal number of controls the average duration of coughing was 6.5 weeks, with a paroxysmal stage of 2.7 weeks.

DISCUSSION

A. J. Scott, M. D. (1401 South Hope Street, Los Angeles).—The use of the Krueger U. B. A. pertussis for prophylaxis is still too new to permit the passing of a positive judgment upon it. This preparation for treatment is apparently not satisfactory because of the large doses, the high cost, and the frequency of doses.

The cough plate method of diagnosis is the most satisfactory, but the technical difficulties of preparation and plate distribution must be overcome before it can be used universally in our private or clinic practice.

Our experience with U. B. A. pertussis is very limited. In the few cases where we have used it for prophylaxis, we have not had any pertussis. We have used it for only two years, and this is too short a time to prove anything. In treatment we have been disappointed, probably because we did not use the large doses Doctor Frawley has used.

In an experience of ten years, from 1925 to 1935, we took 155 cases of pertussis from our personal files. These had no prophylaxis and were diagnosed by blood counts and clinically. We treated them with a stock pertussis vaccine of 7,500 million per cubic centimeter, giving one-half to one and one-half cubic centimeters every other day for three doses. In addition, we used quartz lights and, occasionally, codein. The average amount of vaccine used in 128 cases was 3.78 cubic centimeters per child. The average number of weeks of coughing was 2.36, and the average number of visits was 6.89.

In the California Babies' Hospital, for the same period, we had 2,569 cases. There we averaged 1.75 cubic centimeters of vaccine per child, and the mothers reported improvement in 70 per cent of cases.

We appreciate that pertussis is a variable disease, some years being more severe than in others; also, unless controls are used, as Doctor Frawley says, we can really prove very little. However, we feel that we have had as good results with big doses of stock concentrated pertussis vaccine as have been reported with the more expensive U. B. A. pertussis.

Theoretically, the U. B. A. pertussis is the proper vaccine to use if we are going to use a vaccine. But time and experience will prove whether it is as valuable as the stock H. pertussis vaccine, Phase 1, of our reliable biological laboratories. I hope Doctor Frawley is encouraged enough to continue this work, and to report again what progress he is making.

* * *

Francis Scott Smyth, M. D. (University of California Hospital, San Francisco).—The Pediatric Department of the University of California has been intensely interested in the study of whooping cough. We have learned that it is a more variable disease in its symptomatology than was previously stressed, and were it not for the cough plate many cases, both in adults and children, would go unrecognized. The variability in individual susceptibility, as well as the variation in virulence of the organism, complicate the statistical study of the disease and its prophylaxis. Dr. John J. Miller, Jr., and Dr. Charlotte Singer Brooks have very carefully observed their group of children with sibling control. This method is, of course, more accurate than control cases selected at random. While our earlier studies with U. B. A. were more encouraging, we are not so impressed with the results in this intimate group.

* * *

Charlotte Singer Brooks, M. D. (University of California Hospital, San Francisco).—Doctor Frawley's effort to control whooping cough among school children by the use of the cough plate is very commendable. From the viewpoint of practical epidemiology, the cough plate finds its greatest utility in detecting the early case of whooping cough.

We have been using both U. B. A. and Phase 1 pertussis vaccine in a well-controlled group of children in our pertussis immunization study in San Francisco. The status of Phase 1 H. pertussis vaccine in this group is still an open question. We have not had sufficient exposures among these children to be able to draw conclusions at this time. The incidence of pertussis in our U. B. A. immunized children and control children who have been adequately exposed to the disease has been 100 per cent. The cases of pertussis were of all grades of severity. I believe the criteria of adequate exposure need to be stressed before concluding that immunization is efficacious. Indirect exposure to an early case, or direct exposure to a child late in the paroxysmal stage, may not mean exposure to living H. pertussis bacilli. It is well known that positive cough plates are obtained with difficulty, and often not at all late in the disease. Not until definite standards or criteria of exposure are used, and the status of natural immunity is determined, can conclusions be drawn as to protection of immunized children.

I regret that our experience with U. B. A. in treatment of pertussis cases, well controlled, has been most discouraging. We are not able to confirm Doctor Frawley's splendid results, nor those of Stallings and Nichols, with this agent. The disease in our treated cases was of practically the same duration and severity as in our control cases, regardless of the stage of the disease at which the treatment was instituted. Details of our experience with the therapeutic value of U. B. A. in the treatment of pertussis are to be published shortly.

It is well known that commercial U. B. A. endo-antigen contains very small amounts of protein nitrogen and that there is a variation of the amount in each lot. The lyophil process might serve to concentrate this antigen and standardize its nitrogen content. A study of the therapeutic value of a standardized concentrated U. B. A. antigen would be of scientific interest. However, the results of our experience with the present expensive commercial product make it doubtful whether the additional expense of such concentration and standardization is warranted.

* * *

Edward B. Shaw, M. D. (384 Post Street, San Francisco).—Doctor Frawley has detailed a method for the early recognition and subsequent isolation of whooping cough cases which is perfectly feasible, but which can be accomplished only by means of painstaking care and close coöperation between school authorities, parents, children, school nurses, and physicians. The severity of the disease entirely justifies the labor involved. It should be pointed out, however, that although whooping cough is hardly more than an annoying problem among school children, it is a much more serious one in the home among children below school age, especially infants, and methods of control in the home are of far greater importance than those for the schoolroom.

When one member of a family develops recognizable whooping cough, other members of the family have almost inevitably been exposed and will usually develop the disease in the absence of immunity. Parents and physicians frequently lose sight of the fact that it is worth while to endeavor in every way to diminish the *intimacy of exposure* of well children to those affected with the disease. Cases which develop from intimate exposure (secondary cases in the family) are commonly more severe than is the original. Even though absolute isolation cannot be maintained in the home, every effort should be made at segregation of the ill child, thus reducing the exposure dosage to which other members of the family, frequently smaller children, are subjected.

I am in agreement with the moderation of the author's viewpoint concerning prophylactic and therapeutic use of vaccine. The prophylactic use of vaccine seems commonly to have been accepted with an enthusiasm scarcely justified by the available data. There is no question as to the extreme desirability of a method for immunization, and there seems to be little reason to fear dangerous effects of the vaccine, although the repeated injection of large amounts of the preparation is somewhat of an unpleasant ordeal for little children. The degree and duration of the protection so conferred is, however, most difficult of precise evaluation. There is no simple test for immunity. There is no evidence to suggest that the immunity will be enhanced and maintained by a natural method of immunization. The duration and effectiveness of immunity can be determined only by prolonged observation of the response to natural exposure among large groups of vaccinated and unvaccinated children. There are many variable factors which are most difficult to control. The accumulation of adequate data will not quickly be accomplished, and the widespread employment of active immunization, except on an experimental basis, should be deferred until the questions involved can be answered with authority.

PRACTICAL QUANTITATIVE PERIMETRY*

By David O. Harrington, M.D.
San Francisco

Discussion *by George L. Kilgore, M.D., San Diego; Clifford B. Walker, M.D., Los Angeles; Joseph William Crawford, M.D., San Francisco.*

THERE have been many definitions of the field of vision. Some of them are very ingenious in their method of clarifying a difficult subject, but many of them, although technically correct, are clinically worthless.

By far the most lucid and understandable of these definitions, and the one which best explains and illustrates the problems of modern quantitative perimetry, is that of Traquair.[1] In this definition, the field is imagined as an island of vision surrounded by a sea of blindness.

The island is oval in shape and the coast line rises steeply, as cliffs, vertical on one side and sharply sloping on the other. Above the cliffs is a sloping plateau which rises more rapidly again toward the somewhat eccentrically situated and sharp summit. To one side of this point is a pit (the blind spot) extending down to the level of the surrounding sea.

To an observer situated in the air, above the pinnacle of the summit, a panoramic view of the whole island is presented. Now, conceive of the surface of such a hill as not stationary but subject to slight fluctuations in height, distortion or partial destruction with depressions of every variety occurring on its surface, of all sizes, shapes and depths, and we have a picture of the normal and pathologic field of vision.

CHARTED PERIMETRIC FIELD A CONTOUR MAP

Modern quantitative perimetry is a true *survey* of this hill with all its different levels, dips, and depressions shown by contour lines. Thus, the perimetric field, as charted, is a contour map. It is no longer sufficient merely to outline the coast of this island or very deep depressions in its surface. On the contrary, it is the shallow, barely perceptible indentations which give us the earliest and most valuable information.

In spite of the seemingly complicated nature of this type of examination of the field of vision, it requires in reality only the utilization of a few simple principles and the simplest and most inexpensive equipment. It is, therefore, eminently practical and of the greatest value for routine use in the office of the busy practitioner.

PERIMETRY METHODS

Surprising as it may seem, almost half a century was allowed to elapse after Bjerrum[2] discovered the value of his consulting-room door as a perimeter, before even a limited enthusiasm was aroused by his method. This apathy has persisted in spite of the early recognition of his work by Sinclair[3] and its more full development by Ronne,[4] Walker,[5] and Traquair. It is safe to say that at the present time there are many ophthalmologists, neurologists, neurosurgeons, and others, to whom the accurate charting of the field of vision is of the greatest value, who are not fully cognizant of quantitative perimetry and its possibilities. Of those who use it properly and to its full advantage, there are probably only a handful.

Any attempt to introduce or advocate a method of examination which is cumbersome and lengthy, no matter how excellent theoretically, is bound to end in failure if it has not a highly practical aspect which will recommend it to many men for their routine use.

It was Clifford Walker who showed that quantitative perimetry *could* be a practical method of examination. In doing so, he has gone into the mathematics of tangents, visual angles, distances, time, etc., all of which have been necessary and of great value in the development of the science of perimetry. The complexity of the subject, however, has frightened many men into neglecting it, and yet it is upon this complicated foundation that the present-day clinical methods of field-taking and interpretation are built.

When we speak of practical quantitative perimetry, we must necessarily confine ourselves to a working method which is applicable to all types of cases and which can be used in routine office practice. Walker and Traquair have shown us the way by developing a practical clinical method of perimetry. It behooves all of us to take full advantage of their methods of examination.

For a study of the visual fields, two types of examination are necessary. The perimeter is used to obtain information of the peripheral field and the field for large visual angles, while the more detailed study of the central portion of the field is carried out on the screen.

PERIMETER AND SCREEN

The instruments necessary are simple and inexpensive.

The Perimeter.—The perimeter for use at distances of 300 and 330 millimeters may be any one of the various types now on the market at prices ranging from $300 down. An inexpensive arc perimeter with dull black surface, mounted on an adjustable table is sufficient. If one can have the illumination on an arm of the perimeter, it is advantageous but not necessary. Peter's[6] point is well taken when he states that the illumination should be a constant factor and that perimetry should be done in a dark room with artificial "daylight screened" illumination. This applies both to the perimeter and screen, and it is an easy matter, by means of filters and perhaps a rheostat, to measure the light intensity on the surface of the screen or on the perimeter arm by means of a common light meter borrowed for the purpose from the electric company. Once the desired light intensity has been found, the rheostat can be marked with a file and the light kept constant.

The Screen.—The screen, mounted on the dark-room wall, takes up practically no room and is of the simplest design. A frame of soft pine wood, reinforced at the corners, approximately 70 by 70 inches in size, can be made by any carpenter. The size largely depends on the wall space available. On this frame is stretched a sheet of black felt or heavy black cotton velvet. This can be purchased in two-yard widths, unseamed. I prefer not to mark or stitch the surface of the screen in any manner, relying instead on the tangent rule designed by Sinclair for transferring the field from screen to chart. With an unmarked screen, the fixation point may be moved about on its surface for short or tall persons, or from one side to the other in studying scotomatous areas in the region of the blind spot.

Sinclair's tangent rule may be made by planing the figures off a meter stick and marking in the tangent scale in ink. The rule is marked on one side for fields taken at one meter, and on the other side for fields taken at two meters. The stick is then revarnished. Figures for marking this rule may be found in the appendix to Traquair's textbook. It is a most accurate and convenient way of transferring the field from screen to chart.

TEST-OBJECTS

For test-objects those designed by Behrens, obtainable from Meyrowitz of New York, are preferable. These are spherical-headed pins ranging in size from one-half to five millimeters in white, with two-millimeter pins in red, blue, and green. They are sturdily made, and when soiled can be wiped off with a moist cloth, a distinct advantage over the paper discs generally used. Their surface is dull, so that no undue light is reflected from them. For larger objects, dull paper or cardboard mounted on black pins are easily made.

As a test-object carrier, one can cut the point off a Chinese knitting needle and then rub the needle with lamp black, giving it a durable, dull black finish. These needles are made of a fibrous, rather porous reed, into the end of which the test-object pins can be easily inserted.

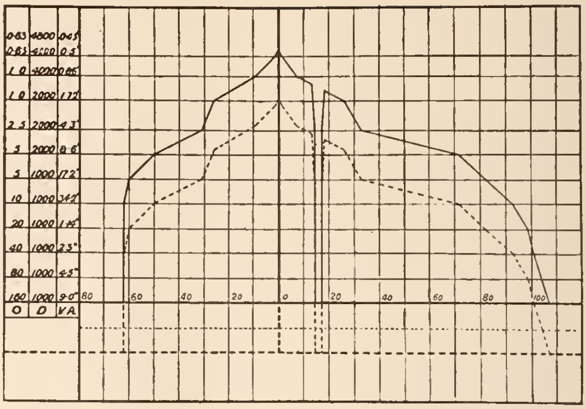

Fig. 1.—Horizontal section of field of vision. (From Traquair.)

A blackened orchestra leader's baton makes an excellent carrier.

I wish to emphasize that it is not necessary to have the best equipment, but that the utilization of simple principles on simple instruments is one of the basic advantages of this method of examination. Indeed, even Peter, who believes that quantitative perimetry has only a limited value and adheres to the qualitative methods of Ferree and Rand,[7] with pre-exposure and testing of color sensitivity, states that "the special advantage of quantitative perimetry lies in its simplicity."

The most easily used charts are probably those designed by Walker. They are accurately printed in terra cotta ink so that the field, when marked, stands out sharp and clear. They should be made of tough paper so as to withstand filing and other rough usage. Their size is a matter of individual preference.

The entire equipment necessary to do good perimetry, including a moderately priced perimeter, screen, lights, test-objects and tangent rule, can be obtained for from $50 to $60—a very modest investment when one considers its value.

STANDARDIZATION OF METHODS

Standardization of methods of perimetry, charting and nomenclature, are things greatly to be desired, and the surest way to accomplish this is to simplify the procedure and equipment so that it is within the range of everyone. The examination should be made in the dark room, with artificial illumination of a standard number of foot candles. The seven-foot candle-power of Ferree and Rand may be used on perimeter and screen, and is easily obtained and maintained constant. Test-objects should be clean and graduated in millimeters, and should be so noted in charting. Thus, Traquair's method of charting the size of the test-object as the numerator of a fraction, and the distance from screen or perimeter as the denominator, will tell at a glance the method of examination used. Any number of contour lines or isopters may be transferred to a single chart,

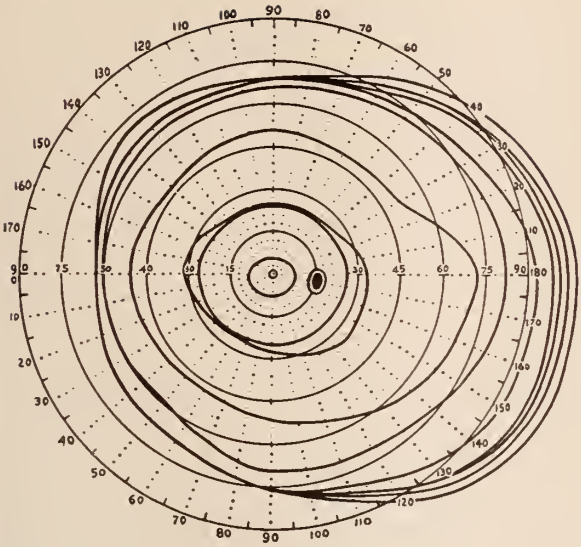

Fig. 2.—Plan of the visual field showing the same Isopters as in Figs. 1. (From Traquair.)

each with its appropriate notation. In this way the field picture in quantitative form may be seen at a glance.

SET ROUTINE DESIRABLE

In outlining a method for taking fields, it is well to follow a set routine designed to get the most out of the field in the minimum of time and with the least effort.

Examination on the perimeter, important as it is, may be delegated to a well-trained nurse. Here we are working with relatively large objects at short distances, *i. e.,* the visual angle subtended is large. We are outlining only the periphery or the coast line of the hill of vision, and the procedure is more or less of a mechanical nature. The examination takes from five to twenty minutes, depending on the complexity of the field. The nurse, unacquainted with the provisional diagnosis and unaware of what field changes to expect, proceeds in a routine manner, using first a three-millimeter object at the usual distance of 330 millimeters, and taking readings on 8 meridia. If defects are found, they are tested with larger objects to determine their density and, if possible, to throw some light on the character of the defect. In this manner the perimetric fields may be examined in every case and often unsuspected defects are found.

Examination on the screen need not be a routine procedure in every case, but should be made wherever there is any reason to suspect a field defect. Thus, whenever the corrected visual acuity is below normal, search should be made for scotomata, enlargement of the blind spots or defects in isopters for small visual angles. Because of the elasticity of the test, it must be performed by the doctor; but in no case should a single examination take more than twenty minutes for each field. It will often be found possible to do it in much less time than this. Examination of the field, like refraction, must not be unduly prolonged or it loses all of its value. The patient becomes fatigued and often irritable, and this is true not only of neurologic cases but also of perfectly normal patients.

Having already had his field taken on the perimeter, the patient is aware of what is expected of him. A few well-chosen instructions as to fixation will put him further at ease. He should be allowed to see the test-object on the end of the pointer and then, as a further test of his concentration, and intelligence, his blind spot is quickly found and outlined. The size of test-object with which to start is determined largely by the patient's visual acuity. This is a matter of experience, and can be judged very quickly after a few trials.

In cases where central vision is 20/40 or better, I usually start with a 2-millimeter object at 1,000 millimeters, or a 3-millimeter object at 2,000 millimeters. After outlining the blind spot to determine its size, and whether or not there are any prolongations present, peripheral limits of the four principal meridia are then found for this object. The object is moved from blind to seeing area; and, having determined these four meridia, the object is moved in a circular fashion around the screen and just inside the previously determined peripheral limits. At any point at which it disappears, a pin with a dull black head is stuck in the screen as a marker, and another to mark its return to the seeing area.

If no defect is found, a smaller object is used, usually one millimeter, and this is carried in to the center on each meridian. When areas or quadrants of blindness are found, these are carefully outlined, both radially and in a circular manner, with large and small test-objects. In this way, what may at first have appeared as an isolated scotoma can often be traced to a connection with the periphery or the blind spot, or both. What may seem to be a quadrantopsia with one test-object will, with another, show up as a large arcuate scotoma.

With the field outlined for one eye with black-headed pins, the other may be designated with pins of a dark gray color. At the end of the examination it may be transferred immediately to the chart with the help of the tangent rule, or may be left on the screen until leisure permits its recording.

In cases where one has good reason to suspect a very small defect in the central portion of the field, or where amblyopia due to tobacco and alcohol is present, colored test-objects may be used. It is somewhat doubtful whether these are of value when used beyond 10 to 15 degrees from fixation. In the peripheral areas of the field more information is obtained by reducing the visual angle for form. In minute central scotomata, however, such as those seen in the early stages of senile macular degeneration or in the amblyopia exanopsia found in a squinting eye, the use of two-millimeter red, blue, or green test-objects is often of great help.

Except in very complicated field defects or in patients whose cerebration is very slow, all of these tests may be done in a relatively short time. In spite of short cuts, one can develop a surprising degree of accuracy and obtain important and valuable information. As stated above, the detailed research type of perimetry advocated by Ferree and Rand, and by Walker, is not necessary for practical clinical perimetry.

In the quantitative method the arc perimeter and the Bjerrum screen are used as part of the same examination, supplementing each other, no matter what the type of defect may be.

IN CONCLUSION

Our problems in ophthalmology have been vastly simplified by the development of a highly accurate method of functionally testing the visual sensory apparatus.

The equipment necessary is simple and inexpensive.

The examination is not difficult nor unduly time-consuming, *i. e.*, it is clinically practical for routine use by the busy practitioner.

Quantitative perimetry is as important a part of the subjective examination of the eye as ophthalmoscopy is of the objective examination, and when properly conducted gives as much information.

This examination should be a routine ophthalmic procedure in which a definite standard of illumination, test-objects, charting, and nomenclature should be adopted.

Because the method offers so much valuable information, this paper has been presented with the hope that it may encourage more ophthalmologists to adopt as a routine office procedure a simplified and practical quantitative perimetry.

DISCUSSION

George L. Kilgore, M. D. (625 Bank of America Building, San Diego).—We should be deeply grateful to Doctor Harrington for bringing the subject of practical quantitative perimetry to us in such a clear, concise manner. If I interpret the meaning of this paper rightly, it is to place emphasis not so much on the need of a very thorough technique in the taking of perimetric fields and in doing tangent screen studies, but to stimulate and encourage a more frequent routine use of these adjuncts to a better diagnosis. No one can deny the need of this encouragement and stimulation. I shall repeat the statement that many ophthalmologists, not particularly interested in the neurologic aspects of the specialty, have a fear of the problem on account of its apparent complexity, and seldom do even a rough examination of the visual fields.

A thorough history in all cases in which there are symptoms relative to a central nerve-system disorder is most important. The ophthalmologist should be on the alert for any symptoms, for we all know that it is impossible to make a correct diagnosis of these lesions without an exhaustive study of the fundi and visual fields. The study should be based on a thorough knowledge of the central nerve system diseases, arising from local intracranial and spinal lesions, general disorders, and toxic disturbances. The finding of symptoms such as headaches associated with nausea, nausea and vomiting, skin areas with abnormal sensations, auras with defects of smell, etc., and symptoms referred to the extremities, should be followed with the most thorough perimetric and tangent screen tests.

I shall repeat, for emphasis, the necessity of obtaining a complete coöperation of the patient in carrying out the work. I have found that most patients require some instruction as to the purpose of the tests, along with an actual application of the several phases of the technique. They respond much better to several trials rather than a prolonged examination. In this manner, the patient is usually mentally fresh, somewhat limiting the fatigue element.

⁂

Clifford B. Walker, M. D. (427 West Fifth Street, Los Angeles).—To Doctor Harrington we are indebted for a most excellent paper, which I believe represents a praiseworthy attempt to put perimetry on a more available, perhaps even routine basis.

As far back as 1921[1] I first also attempted to set forth in a somewhat similar paper how easily quantitative perimetry could be managed. I apparently waived the fact that I had already been giving the general subject of perimetry very special attention for ten years. I naïvely assumed that my readers had a preliminary education (or experience) somewhat similar to mine and would be eager, willing and *able* to run about gathering the numerous necessities described. I found that this assumption was rarely true. In the course of time my viewpoint gradually changed, until recently I seem inclined to remark: "There is no royal road to neurological ophthalmology, commonly called perimetry."

Perhaps a hasty field is better than none. Yet a rapid fruitless field may permit, let us say, for instance, an early undiagnosed pituitary case, to say, "Yes, my fields have been taken and they are all right." If further work is thus inhibited, a costly sequel may later result.

One constant characteristic of the field that turns out to be worth something, in a diagnostic way to the doctor and the patient, is that it took time to make the examination and permanently record it.

In a way, Doctor Harrington seems to intimate that the nurse or technician first makes a complete perimetric record in five to twenty minutes, using test-objects from 3/330 up if necessary on eight meridians, screen work being waived in most cases. This routine might seem a dangerously close approach to the action point of a law of diminishing returns.

If I had to pass routinely in five or twenty minutes on the functional normality of many retinas, I believe more loopholes would be closed by reversing the procedure. That is, test the blindspot first in order to judge the values of the answers, then outline the 26-degree normally round critical field of the 1/2000 test-object, and then ophthalmoscopically examine the peripheral retina if no more time is left for the perimetric work. This much can actually be recorded in twenty minutes. and will more safely obtain higher percentages of valuable information, because if this critical test, as I call it, is not passed, more time, often over an hour, may be spent in completing a quantitative perimetric record of diagnostic value.

Time permitting only a closing remark, may I merely note that velvet is very apt to glisten undesirably in the light and is more likely than felt to tenaciously hold whitish specks of lint, etc., quite difficult to brush off.

Again, time savers should not overlook the fact that, with Doctor Harrington's unmarked screen, much time in recording is necessary. In his description no accuracy of measurement is stipulated as regards meridians. Guessing them may result in mistakes of five or more degrees if done hurriedly. He directs the perimetrist to go to Traquair and find out for himself what numbers to put on his one-meter ruler after he has skillfully planed the ruler bare to receive them. Yet I find no mention of the protractor necessary to lay off each meridian with the same accuracy with which the distance from the center is recorded. Perhaps it may be fair to state that our perimetrist will have to do a little hunting before he gets a time-saving protraction to fit his planed, perhaps varnished, ruler. Then there will be the plumb bob or level which must be used for real accuracy in establishing the vertical or horizontal meridian as a starting point. Personally, I have long since had enough of time-wasting rulers and protractors in quantitative perimetry; they do not fit the twenty-minute picture unless several of the said eight corners are cut, or accuracy is otherwise allowed to become the weak link.

⁂

Joseph William Crawford, M. D. (490 Post Street, San Francisco).—Perimetry furnishes a functional test of the entire visual sensorium from the brain to the end organ, or retina. An objective examination of the visual tract *in vivo* is for the most part impossible. Disturbances in function of such a highly organized structure precede, as a rule, recognizable alterations in its architecture.

The only instruments necessary are an arc perimeter and a tangent screen, the former to define the peripheral limits of the visual field; the latter to study more minutely the central and paracentral field. No ophthalmologist or neurosurgeon should limit himself to either instrument, but should use one to supplement the other. The tangent screen, devised by Ferree and Rand, which may be attached to their perimeter, is a very good one; but for routine use in the office or clinic, a large one, such as that described by Doctor Harrington, or the one described by Clifford Walker, is more useful. One other instrument that deserves wider use is the small hand campimeter devised by Peter. For patients too ill to be moved about, and for rapid routine office and clinic work, it furnishes accurate information with a minimum loss of time and effort.

The usual procedure with the tangent screen is to use a form stimulus subtending the smallest visual angle easily recognizable by the patient and, in addition, stimuli of different colors, usually blue, red, and green. The purpose of the test is to determine the "point in the field at which the stimulus in question is of threshold value for the light and color sense" (Ferree and Rand).

Stimuli of different colors are advocated because of their increased sensitivity in slight pathologic alterations; but there is undoubtedly also a special and differential susceptibility for colors in pathologic disturbances. Peter points out the fact that the blue field suffers first in nutritional disturbances, affecting the neuro-epithelial layers of the retina; whereas the green and red fields suffer first in disease of the nerve fibers.

All of us have observed the early and complete disappearance of the green field in tobacco-alcohol amblyopia, with preservation of the blue field.

A modification of the method described above for studying the central and paracentral field, is the method termed "quantitative perimetry." The technique of this method has been described by Doctor Harrington and consists essentially in substituting for the color stimuli, white stimuli of various sizes. Advocates of this method argue that a decrease in the size of the stimulus increases the sensitivity of the perimetric method; but, as Ferree and Rand have pointed out, "such extremely small stimuli are sometimes used that they are more properly test-objects for visual acuity than for the sensory process." They recommend, rather, that form stimuli be used only until the level of visibility of the color stimuli is reached. Beyond this point color stimuli are more informative.

No ophthalmologist or neurosurgeon can afford to limit himself to either quantitative or qualitative perimetry, for each has its sphere of particular usefulness. No one can gainsay the value of quantitative perimetry in neurologic cases. The information gained from neurologic patients by using color stimuli is of no more value, certainly, than that obtained by using small white test-objects; and as it calls for more intelligence and coöperation from people who are obviously quite ill, it is probably less trustworthy.

However, most ophthalmologists who have to deal with many more cases of ocular disease than neurologic disease, will get more valuable information from a routine study of the visual field, using form and color stimuli, than from a study confined to the use of form stimuli alone.

SILICOSIS*

By Philip H. Pierson, M.D.
San Francisco

Discussion *by W. P. Shepard, M.D., San Francisco; L. Henry Garland, M. D., San Francisco; Munford Smith, M. D., Los Angeles.*

So much has been written on silicosis from its historical and clinical manifestations that I will not go into detail on those phases, but will discuss some of the conditions which have led up to the "racket" which now exists in this field and some of the means at our disposal, as physicians, to help control it.

What are some of the factors which have produced this state of affairs? There are numerous causes, but I will mention only the following: (1) An increasingly large field in industry, where silica or silicates play a part—mining, quarrying, sandblasting, manufacture of polishes, molding, glass making, tunneling, besides the asbestos and talc industries. (2) More widespread appreciation of the presence of dust-borne diseases and their differentiation from tuberculosis. (3) An unrest among "Labor" because of working conditions or wages, which has led them to attack "Capital" in the form of suits for damages, some of which are justifiable and some not based on true facts. (4) Unscrupulous or misinformed lawyers and doctors have been led to plead and testify in cases called "dusty" without knowing the true facts about silicosis, but acting on presumptive knowledge.

AN INDUSTRIAL PROBLEM

It has been said that 500,000 workers are exposed to silica and potentially each of these persons is subject to silicosis. It, then, does constitute a problem worthy of our consideration. And perhaps the fact that our attention has been particularly focused on it is a blessing in disguise. In California, and a few other states, silicosis is a compensable disease. Our laws at present are so worded that a workman may and must apply for compensation insurance within a period of six months from the time that he has symptoms referable to this disease. By the time symptoms have appeared the condition must have been present for some time, and it is likely that disability will be progressive thereafter. The problem facing the insurance companies is to charge rates sufficiently high to cover all probable liabilities, and all employers within a given industry must pay approximately the same rates. In view of the fact that the development of silicosis may be delayed for months or years after an employee leaves one position, a new problem is added; for previous exposures in dust hazards are proportionately liable, and the employee may exercise his right to compensation some time after premiums cease to be paid. Wet mines or those relatively free from dust have had to suffer equally with the dusty ones. A type of voluntary annuity insurance might be devised from the wealth of actuarial statistics relative to the length of exposure to certain concentrations of dust and the consequent development of silicosis, so that men could be moved from a dangerous exposure before disease developed; and from the dividends so obtained establish themselves in less dangerous occupations.

---

* From the Department of Medicine, Stanford University.

Read before the General Medicine Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

"Labor" will be very reluctant to enter into any plan of periodic physical examinations of the workers if the object is to expel them from their positions. This has a very meritorious argument in its favor. Workers who are found to be suffering from silicosis, even in its earliest recognizable stages, should be transferred to other phases of the work where they will be safe.

The insurance companies have another problem to contend with, namely, defending themselves against unscrupulous or misinformed litigation; in other words, the "racket." We might define this sort of racket as a situation in which many false claims for damages follow in the train of a relatively new field where danger has been discovered, and where rightful claims amount to considerable sums of money.

A MEDICAL PROBLEM

And now, from the physicians' point of view, what are our problems? We are called upon to examine men, evaluate their history as to exposure in so-called dusty occupations, interpret the roentgenograms and other laboratory data, and give an opinion as to whether disease—silicosis—exists. Under our present system this entails many difficulties, chief among which are: (1) what do we mean by the term "dusty"? and (2) the differentiation of silicosis from tuberculosis and other diseases causing a pulmonary fibrosis.

THE PROBLEM'S SOLUTION

There is no doubt that a tremendous danger lurks in those industries above mentioned where the laboring man is exposed to high concentration of fine silica dust over long periods of time. And even with the knowledge that we have at hand, I think this does not present an unsurmountable problem. If an epidemic of scarlet fever, typhoid, or smallpox breaks out, our Boards of Health know the sources and put into operation at once the machinery to stop them. They are also aware that without proper precautions such epidemics might easily occur today, and these preventive measures are strictly enforced every day without our even giving them a thought. To handle the silicotic problem we must likewise know the source or sources from which dangers arise, and meet these dangers with modern medical and engineering skill. And not only must they be met once, but we must meet them constantly if the hazard is to be removed.

Of all dusts encountered in industry those considered most dangerous are silica and certain silicates, such as asbestos and talc. What are the qualifications which determine whether such exposure is harmful or not? From the investigations made by the Bureau of Mines and other commissions, we know that it is dependent upon (1) the total number of dust particles per cubic foot, (2) the size of these particles, (3) their mineralogic and chemical composition, (4) the length of exposure, and (5) the presence of concomitant gases. No industry should be termed harmfully "dusty" without first knowing these facts.

The harmful factors in this dust hazard are silica, certain silicates, and gases. So far it has not been proved that serocite is a harmful silicate, but asbestos (magnesium iron silicate) and talc (hydrous magnesium silicate) have been proved to be dangerous. Furthermore, we know that particles less than ten microns are the ones taken up by the phagocytic endothelial cells and carried through the lymphatics, and that larger particles are generally expelled from the respiratory tract by the ciliated epithelium or caught in the upper respiratory tract, and thus do not enter the lungs.

WHAT MUST BE KNOWN

First of all, how are we to know whether a mine, or factory, or industry is a menace from this point of view? Reliable dust counts made where the person is employed, and at a level of the worker's mouth, is most important. This analysis is a highly technical procedure, and must be done by a chemist trained in this field. At present the Greenberg-Smith impinger is the most accurate instrument for making these counts. As the very fine, invisible particles may be thrown high in the air when work is first begun, it is wise to make correlating counts some hours later. In the counting of the particles we must know how many are present per cubic foot and the percentage that are under ten micra. An analysis of the rock or substance used should also be made, and all its components quantitatively known. The dust inhaled may not be in exactly the same proportion as in the original material, and so it is necessary to analyze the dry or wet settled dust collected from ledges or rafters. That data, taken in conjunction with the dust count, tells us the size and number of particles of the minerals inhaled. From the statistics compiled by many surveys it is known that the hazard is in proportion to the number of fine particles, their composition, and the length of exposure. Quoting from the Pennsylvania Surveys, Anthraco-Silicosis, 1934: "Employment in an atmosphere containing less than fifty million dust particles per cubic foot would produce a negligible number of cases of anthraco-silicosis when the quartz content of the dust was less than 5 per cent. In the gangways, where the silica content of the dust was about 13 per cent, a safe limit appeared to be ten to fifteen million particles per cubic foot. The limit of tolerance for rock workers was set tentatively at five to ten million dust particles per cubic foot of air."

The chemist should also make a determination of the gases present in the environment of the workers. Banting, in his recent observations, has shown that nitrous acid and sulphur so irritate the normal lining of the bronchopulmonary tree that silica crystals are more readily absorbed, and hence disease develops more rapidly.

The second analysis should be of the workers. This means not only good stereoscopic roentgenograms intelligently interpreted, but examinations of the workers—a history of past exposure to dust (and its type), acute and chronic respiratory diseases, and evidence of tuberculosis. (An interesting and helpful survey might well be made of the incidence of tuberculosis in the population of the community where the miners live, as in such a community a large proportion of the inhabitants work in the mine; and the tuberculosis hazard may thus be estimated.) The examination should include a complete study of the respiratory tract. A simple exercise test (the chair test) is helpful in determining the cardiac and respiratory reserve. Expansion of the thoracic cage and excursion of the diaphragm in the fluoroscope will aid in determining the amount of emphysema resulting from the pulmonary fibrosis. It is well known that fibrosis from a dust exposure may not make its appearance for some time after the exposure. Severe respiratory disease often greatly accelerates the development of the fibrosis. These are reasons why it is unfair to the worker to place a time limit in which he may make a claim.

If these two examinations are made correctly they should check each other, for if serial examinations of the men show the development of silicosis in the face of a negligible dust hazard, it is evident that the men have been previously exposed or that the count is inaccurate. This statement implies the necessity for periodic examinations, every six or twelve months, of the men and the dust. If a dust hazard is found and corrected by water properly applied, better ventilation, opportune time of blasting, and so forth, subsequent dust counts will show this improvement.

A very important phase of this problem must be carried on by the pathologist. As has been said, the difficult case to accurately diagnose is the one where the exposure has been relatively short and the fibrosis has not developed beyond a slight degree. Pathologic and mineralogic analysis of these lungs at autopsy will go a long way in determining the type and amount of disease present so that roentgenograms may be more accurately interpreted.

REPORT OF CASES

As examples of testimony given without sufficient knowledge of these underlying conditions, may I cite from two industrial cases I recently studied:

Case 1.—A man had been employed as a machinist, and his duties involved trimming steel objects on a lathe. Rather suddenly he developed cough, expectoration, shortness of breath, and loss of weight. X-ray examination of his lungs was made and he was sent to a tuberculosis sanatorium, where tubercle bacilli were found in his sputum. After a few months of improvement he left and came into the hands of a good physician, who felt that his "dust" exposure might be a factor. Other x-rays were taken and presented to several roentgenologists with this story, especially the dust phase of it, and many rendered the opinion that he was suffering from "pneumonoconiosis or silicosis." An analysis of the dust disclosed 2 per cent silica, and the counts ranged from 1.6 to 2.8 million particles per cubic foot. One roentgenologist went so far as to state, "The x-ray appearance is typically that of pneumonoconiosis, and this diagnosis can be made without the clinical findings and occupational history, but the latter is confirmatory evidence."

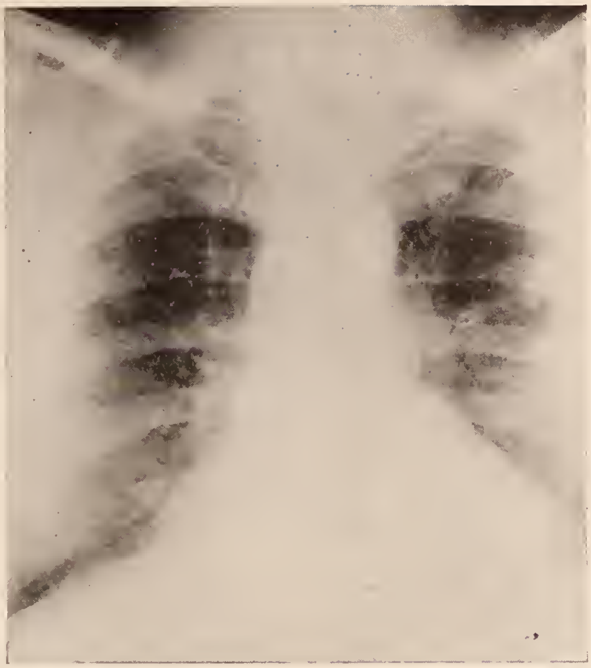

Fig. 1.—Mr. W.—Asbestosis. Note fine diffuse linear thickening giving ground glass appearance

This is an example of what I mean by presumptive evidence. The difficult cases to properly evaluate are not so much the late cases where silicosis is definitely established by a long history of exposure and roentgen shadows which appear quite typical of silicosis, but in the earlier cases where a diffuse fibrosis exists with a shorter period of exposure. Many conditions may cause a diffuse fibrosis—tuberculosis, chronic bronchosinusitis, bronchiectasis, chronic pneumonia, and so forth. It is here that research into the pathologic study of these cases is greatly needed.

* * *

Case 2. — My second example illustrates a mistake I made a few years ago. A patient of mine had had thirty-two months' exposure to silica dust in a plant where enameled tubs and bowls were made. In this industry, sandblasting and emery-wheel grinding were frequently employed. The man had a tuberculosis which was treated by artificial pneumothorax. A diffuse, fine fibrosis was present in both lungs, and in places a fine nodulation. After considerable hesitation and study, I came to feel that perhaps this was evidence of the irritation from the dust he had inhaled. He died and we made an examination for silica in his lungs, which showed no more than is found in normal individuals. Consequently, I had to admit that my diagnosis was wrong.

Much light would be thrown on this type of case if more such studies could be made. I cannot emphasize this point too strongly, and hope that wherever such opportunity arises specimens of lung tissue will be submitted to mineralogic and pathologic study. I have recently heard of a case where the diagnosis of siderosis was made because some iron particles were found in the lungs. It is the feeling of those best informed that iron in the lung produces some pigmentation, but very little fibrosis, and that there is not a particular predisposition to tuberculosis.

TABLE 1.—*Mr. W.—Summary of Industrial and Clinical Data*

Name Age Sex	Length of Exposure	Location of Exposure	Previous Dust History	Past History Respiratory Disease	Past or Family History Tuberculosis	Physical Examination Respiratory Tract Chest Expansion Chair Test	X-rays
W. 58 M.	Twenty-five years, forty hours a week, plant superintendent in asbestos department four to five hours a day. This is equivalent to 12½ years' constant exposure.	Zones 1, 2, 3, 4, 5. Dust counts 4-25 million particles per cubic foot. 80 per cent less than 10 micra. 84 per cent asbestos.	Kesby and Mattison Counties. "Roustabout in clean and dirty rooms."	Typhoid pneumonia at 18	None	Weight 186½. Eyelids puffy and injected; nose, poor space. Heart, negative. Lungs, diminished breath sounds throughout; at left apex, increased whisper and a few râles. Blood pressure, 160/94. Fluoroscopy, general haziness throughout both lungs with enlarged hilar glands. Diaphragm, right, 1 centimeter; left, 2 centimeters; chest expansion, 1 to 2 centimeters. Chair test, 25 steps. P. R. Before exercise .... 92 20 After exercise .... 124 24 After two minutes' rest........ 108 24	Moderate enlargement of heart, increased diffuse granular peribronchial markings throughout both lungs. More pronounced in lower lung fields. Coalescing larger areas in left lower lobe. Diagnosis: Evident asbestosis in both lungs.

COMMENT

With all these points in mind I feel that we, as physicians, should be much more careful in stating in a given case that a patient is suffering from silicosis, and before rendering such an opinion we should know the length of exposure, the minerals involved, the type of dust hazard and its specific reaction, and that we should not make statements or give opinions which carry considerable weight until we know as much as can be determined in each individual case.

If such surveys as these were started in all dusty industries, would we not lay the foundation for more accurate knowledge and, what is of more importance, greater safety for the worker? This, as I have said, would mean lower insurance rates, and in these factors I think both Capital and Labor would profit. Why spend time and money building up reserves against damage suits when a great many would be averted by healthier working conditions? Is there not an opportunity and need for a responsible, unprejudiced institution to which such problems as dust hazard and health surveys may be brought and from whose findings sanitary engineers could, by their skill, work out their solution? An accurate foundation must be laid, and the sooner it is done the sooner will the rightful case receive proper recompense. Moreover, it will stop the "racketeering" where silicosis does not exist.

Labor will not coöperate in any plan of physical examinations of workers if the purpose of the same is to discharge men when early or more advanced fibrosis is found. The employers must prepare themselves so that when employees with disease are found they may be transferred to other occupations free from the dust hazard. This type of mutual assistance will help the employer by keeping his workmen fit, and it will appeal to the labor organizations, for their men will be continued at some type of work which is safe.

IN CONCLUSION

In conclusion, may I illustrate some of these factors in an analysis I recently made of an asbestos factory. Six workers were examined in the manner illustrated in the chart on the tripod. Dust counts were made in different parts of the factory where exposure was taking place, and it was found that they varied from six to twenty-four million particles per cubic foot, and that the dust contained 84.48 per cent of asbestos, 80.36 per cent of the fibers being less than 10 micra in length. One employee had definite asbestosis, one was questionable, and the others were given a clean bill of health. By a better enclosure of the saw which caused the dust, this hazard was reduced to one employee, who could be properly protected, and their liability was minimal. A base line for the health of their employees was established, which will be of great assistance in comparison with the subsequent periodic examinations and dust counts.

SUMMARY

Silicosis (as a compensable disease) has become a "racket" because of many factors, chief among which are the lack of accurate knowledge as to the working conditions in certain industries and the loose use of terms based on presumptive knowledge.

It is possible to properly evaluate the hazard of silicosis by reliable dust counts, and competent and intelligent medical and roentgen examinations.

These complete examinations must be repeated periodically to determine whether the hazard has been removed and whether the health of the worker is such that he may continue in his occupation.

Replacement in less hazardous positions must be a part of the program if Labor is to be fully coöperative in this plan.

Actuarial statistics may be used to promote a type of insurance which will act as an annuity for those who change their work before trouble develops and thus make the transition from one occupation to another an easier procedure.

490 Post Street.

DISCUSSION

W. P. Shepard, M. D. (Metropolitan Life Insurance Company, 600 Stockton Street, San Francisco).—We must admit that Doctor Pierson has called our attention to one of the most urgent problems confronting industry and medicine in this State today. Like many industrial-medical problems, there is much confusion both in medicine and industry concerning silicosis—a clinical entity about which we have considerable knowledge. There is pressing need for each of us who come in contact with the dusty industries to impart the following facts:

1. Silicosis is a disease caused by the prolonged inhalation of finely divided silica dioxid. It is probably only produced when such silica dioxid exists in the air of the working space in amounts in excess of twenty million particles less than 10 microns in diameter per cubic foot of air. It usually requires prolonged exposure to such concentrations before the disease is produced, perhaps at least two years. In this connection, it is well for us to remember some of the peculiar physical properties of such small particles: (*a*) they do not settle, but will remain suspended in air for a long time; (*b*) they are invisible to the naked eye, so that even in the presence of strong light the air may look clear; (*c*) these particles are not always controlled by water. Wet-drilling only partially solves the problem. This is due to the fact that the surface tension is so great, compared with the weight of the particle, that water will not adhere to the surface.

2. Silicosis, caused by the inhalation of large numbers of finely divided particles of silica dioxid over a considerable time (*a*) predisposes to tuberculosis; (*b*) can be diagnosed before tuberculosis is superimposed; (*c*) and disability can usually be prevented by prompt removal from exposure at early stages. This involves careful periodic physical examination, including x-rays taken by special technique and read by experts with a view to finding the first-stage silicosis cases.

3. Silicates: Only asbestos produces a pulmonary fibrosis which may cause disability. The other silicates have not been shown to cause appreciable pulmonary disease. Asbestosis, as far as we know today, does not carry with it the same predisposition to tuberculosis as silicosis.

4. The dust hazard in a given industry can always be measured, and can usually be controlled.

* * *

L. Henry Garland, M. D. (450 Sutter Street, San Francisco).—The importance of reliable dust counts has wisely been stressed by Doctor Pierson in his very valuable paper dealing with certain aspects of silicosis. As physicians, our first problem in dealing with silicosis is to diagnose it properly. The diagnosis of silicosis is based (1) on the history, (2) the clinical findings, and (3) the roentgen findings. With properly made and interpreted roentgenograms, the roentgen findings constitute the strongest link in the chain of evidence, and the clinical findings the weakest link. However, we heartily agree with Doctor Pierson that the diagnosis of this condition can rarely be made solely on the roentgenograms. It nearly always requires the concomitant history of definite exposure to hazardous concentrations of silicious dusts.

As an example of the differential diagnosis of pulmonary fibrosis based on the roentgen findings alone, I am reproducing the following tables from my paper entitled "The X-Ray Aspects of Pneumoconiosis," which appeared in *Radiology,* July, 1936:

Table 1.—*Lesions Simulating Silicosis in the Roentgenogram*

1. *Incipient Type*
    - Passive congestion of the lungs (cardiac).
    - Acute respiratory-tract infections.
    - Asthma.
2. *Interstitial Type*
    - Passive congestion of the lungs (cardiac).
    - Acute and chronic respiratory infections (especially bronchitis and bronchosinusitis).
    - Polycythemia.
    - Metastatic malignancies, infiltrative type.
    - Mycoses.
    - Lymphoblastoma (infiltrative Hodgkin's).
    - Pulmonary syphilis.
3. *Nodular Type*
    - Miliary tuberculosis.
    - Metastatic malignancies (miliary carcinosis).
    - Periarteritis nodosa.
4. *Advanced Type*
    - Chronic pulmonary tuberculosis.
    - Pulmonary tumors.
    - Pulmonary syphilis.

Table 2.—*X-Ray Findings in Silicosis (Uncomplicated or Simple Silicosis)*

1. *Incipient Type*
    - Hilar shadows wider and denser than normal; perihilar pulmonary tree markings wider than normal.
2. *Interstitial Type*
    - Hilar shadows wider and denser than normal; slight or moderate diffuse thickening of the pulmonary tree markings, associated with faint haze in middle or lower thirds of the lungs in early cases; extensive thickening in well-established cases.
    - Limitation of diaphragmatic excursion (varying from slight to marked).
3. *Nodular Type*
    - Hilar shadows wider and denser than normal; diffuse scattering of small, dense, discrete nodules throughout both lungs, especially in the middle thirds; apices usually free.
    - Limitation of diaphragmatic excursion.
4. *Advanced Type*
    - Hilar shadows less prominent than usual; diffuse thickening of the pulmonary tree markings, and/or diffuse nodulations; small or large areas of density due to coalescence of fibrotic or nodular lesions.
    - Emphysema.
    - Limitation of diaphragmatic excursion.
    - Occasional cavitation.
    - Enlargement of the right side of the heart.

For those who are interested in the subject, the minimum requirements for satisfactory roentgenograms of silicosis cases are described in the above-mentioned paper and, also, in Pancoast's article in the *Journal of Industrial Hygiene,* Vol. 16, p. 165, May, 1934.

No matter how detailed a fluoroscopic examination is or how perfect a given set of stereoscopic roentgenograms are, it is to be remembered that the interpretation is the only part of the roentgen examination which is of value. The sooner that more stress is laid upon competent interpretations, and less upon "an x-ray plate of the lungs," the sooner will accurate diagnosis of silicosis be established in surveys of dust workers.

* * *

Munford Smith, M. D. (727 West Seventh Street, Los Angeles.)—It is a pleasure to discuss a paper such as this one by Doctor Pierson, who is familiar not only with the literature on the subject, but has had a large experience in the application of his knowledge of silicosis to many concrete cases. There are, however, some points in his discussion with which issue must be taken, not because he is less familiar with the subject than I am, but because the correction of errors in even little relatively unimportant details may prevent further confusion.

The subject of his paper is "Silicosis." At the risk of being considered hypercritical, there must be objection to the inclusion, as sources of silicosis, of asbestos and talc, both of which are silicates of magnesium and in neither of which does silica exist in a free state except as a contaminant from the quartz which may have bound together the strata of the material in its natural state. Asbestos may produce a severe form of pneumoconiosis; and while talc theoretically causes a silicatosis, which is a form of pneumoconiosis, it is a relatively harmless material, and to my knowledge there is only one reference in the literature indicating that it is capable of producing anything more than a mild fibrosis, this one exception being a report of the United States Public Health Service of a survey of two mines in a county in Georgia with a very high tuberculosis morbidity rate, which is unrelated to the inhalation of talc.

Under the qualifications determining the harmfulness of a dust, Pierson gives as one of the factors the presence of concomitant gases and refers to the work of Banting, who has offered the hypothesis that gases present in the atmosphere of mines irritate the normal lining of the respiratory tract, with the result that silica is more readily absorbed. I believe this theory has not been accepted.

In discussing the legal requirements of the California Workmen's Compensation Laws, as applied to claims for silicosis, Doctor Pierson states that our laws at present are so worded that a workman may and must apply for compensation insurance within a period of six months from the time that he has symptoms referable to the disease. Doctor Pierson's statement is correct, I believe, as to the wording of the law, but in the application of it it is only necessary that the workman apply for compensation insurance within a period of six months from the time that he knows he is suffering from disease and, as a matter of fact, it seems that in the practical application of this part of the law, it is only necessary that he make such claim within six months of the time that he admits he knew of the presence of the disease.

Finally, Doctor Pierson refers to the importance of unscrupulous or misinformed lawyers or doctors in the situation which has arisen not only in California, but elsewhere. As a physician, I am incompetent to judge the ethics of the legal profession, but I believe I am capable of doing so with those of my own. In an experience of well over three hundred cases involving the question of possible harm from dust, it has never been my experience to contact an unscrupulous physician, unless a misrepresentation of his qualifications dependent on knowledge and experience in diseases of the lungs and silicosis could be so classified, but the amount of misinformation possessed by some of the members of both groups has been surprising.

If Virchow was really the father of pathology, he would surely have difficulty in recognizing some of his offspring, if we are to judge by the fantastic theories that have arisen to explain some of the claims of silicosis with which I have come in contact. The explanations sometimes presented in support of the claim of silicosis are so diametrically opposed as to make medicine and chiropractic seem blood brothers.

Some claims for compensation for silicosis, which disease is certified as being present by physicians, not only lack evidence of that disease, but silica dust may be entirely absent from the atmosphere of employment.

As members of a profession who see much of human suffering, probably the majority of us would, if it were possible, prefer some adjustment of the wealth which is so unevenly distributed, and when a claimant who attributes ill health to some factor in industry appears before us, it is easy to permit our sympathies to lead us astray. "Soaking the rich" has been one of the favorite pastimes of recent years. That, in my opinion, is the principal factor in many unwarranted claims. We may even be tempted, since the defendant is a rich corporation, to emulate Robin Hood and take from the rich for the poor. However, our opinion is sought as that of scientists and not as economists of the Huey Long school, and when we accept that position we should function in such a way as to justify the faith placed in us.

To me it seems that if we keep in mind that the claim which we are supporting is one covered by the provisions of the Workmen's Compensation Law, which provides for medical care and payment of compensation for illness or injury incurred in the course of employment, and is not life or health or unemployment or old-age insurance, we may many times avoid a position which can be exceedingly embarrassing.

Finally, it is possible for any physician who is not familiar with silicosis to obtain the essential data on its etiology and diagnosis. Our medical libraries will gladly provide such information.

TRAUMATIC RUPTURE OF THE UTERUS IN ADVANCED PREGNANCY*

By E. M. Lazard, M.D.
and
F. E. Kliman, M.D.
Los Angeles

Discussion *by Sterling N. Pierce, M.D., Los Angeles; J. Morris Slemons, M.D., Los Angeles; Leon J. Tiber, M.D., Los Angeles.*

In presenting the report of a case of rupture of a uterus, eight and one-half months pregnant, by external violence, we purpose to review the literature and consider the mechanics of this accident. We will not consider those cases of uterine rupture through cesarean or myomectomy scars; nor those ruptures occurring as a result of obstructed labor or in the course of operative attempts at delivery or abortion.

CLASSIFICATION

1. Complete, through the entire uterine wall, with complete or partial extrusion of the uterine contents into the abdominal cavity.

2. Incomplete, where the rupture is not through the entire uterine wall. As to location, the tear may be in the upper or in the lower uterine segment, usually the upper when due to external trauma.

ETIOLOGY

While a trauma of sufficient force may cause a rupture in a healthy uterus, yet the presence of a weakened point caused by preceding disease, such as hyalin degeneration of muscle fibers resulting from multiparity, previous curettages, placenta praevias, intramural fibroids, etc., would undoubtedly increase the probability of rupture resulting from external violence.

In a review of the literature, by Estor and Pueck (referred to by Jaroschka, *Medizinische Klinik,* 1929), up to and including 1929, forty cases were found. Jaroschka reported one case, occurring in the Prague clinic in a series of thirty thousand obstetric cases. Orthner (*Münchner Med. Wöchenschrift,* August, 1933), reported an additional case in which the patient had been struck across the abdomen by a breaking trace on a team of horses which she was driving. At operation, one and one-half hours after the accident, the patient was found to have a ruptured uterus, with complete extrusion of full-term twins and placentae into the abdominal cavity.

Orthner gives the following explanation of the mechanics of the injury: As to whether the blow or the resultant fall is the principal factor, he says that as a rule one can assume that whichever is of the greater intensity is the chief factor, *i. e.,* with a slight blow and a fall from a great height, the latter is the main factor; with a severe blow and a short fall to the floor, the blow in all probability is to blame. It is not possible, as a rule, to determine the kind and direction of the force from

* Read before the Obstetrics and Gynecology Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

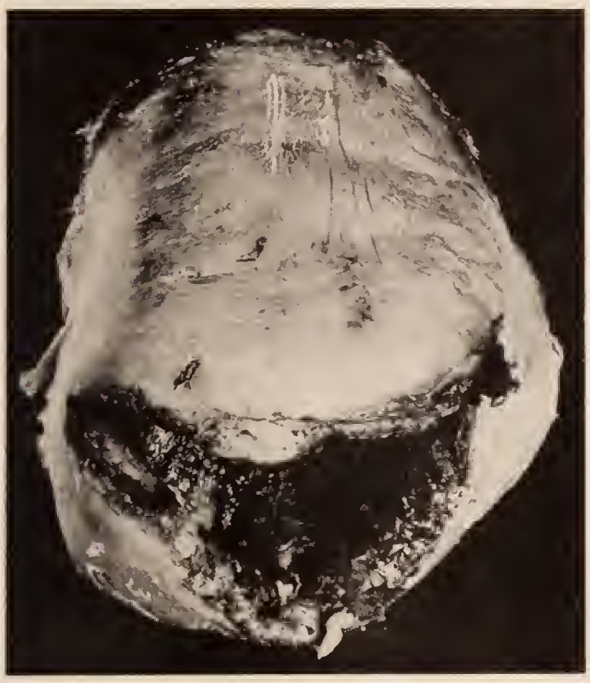

Fig. 1.—Ruptured uterus. Transverse rupture on the posterior surface of fundus.

the location of the uterine rupture, as this usually occurs by contrecoup.

The rupture is always the result of a sudden increase of the intra-uterine pressure, caused by the sudden compression of the abdominal contents.

In accordance with the laws of hydrodynamics, this pressure spreads equally in all directions in the uterine cavity filled with amniotic fluid. The tear occurs at the weakest point of the uterine wall. At the end of pregnancy that point is at the fundus, which, moreover, lacks the protection of the bony pelvis. In many cases it appears that the placental site is especially weak because of the increased vascularity.

The following case occurred in the service of the senior author at the Los Angeles General Hospital:

REPORT OF CASE

Hospital No. 394-515. Gravida 1. Para 0. Nineteen years of age. Admitted December 22, 1934, at 7 p. m. About eight months pregnant. One month and two weeks ago she was under observation for threatened premature labor. At 3:30 p. m. today (four hours before admission), she fell down steps, striking her abdomen on the edge of a step. Did not faint, but had great difficulty in breathing. Has had severe abdominal pain for over one hour. Has had shoulder pain for one hour. She cannot take a deep inspiration. Vaginal bleeding started one hour after fall, and a large gush of blood escaped from vagina. No fetal movements felt since fall. Has infrequent cramp-like pain in lower back and groin. Blood pressure, 128/84. No fetal heart tones heard. Abdomen distended. Fundus cannot be felt. Diastasis recti present. Fetal small parts anterior and seem to be just beneath the skin.

Vaginal Examination.—Cervix admits one finger, not effaced, no presenting part felt in pelvis.

Blood Count.—Hemoglobin, 70 per cent (Sahli); red blood cells, 3,730,00; white blood cells, 34,000; polymorphonuclears, 95 per cent.

Diagnosis.—Ruptured uterus, dead baby; 8:45 p. m., laparotomy, abdomen full of blood and contains fetus in intact amniotic sac and placenta. Uterus contracted down, and has a tear across the posterior surface of fundus (see specimen). Supravaginal hysterectomy done, followed by blood transfusion. Uneventful convalescence. The patient was discharged in good condition on January 2, 1935 (twelfth day).

*Pathologic Laboratory Report.**—Two microscopic sections were examined, one taken from the myometrium adjacent to the laceration in the uterine wall. This section shows typical structure of the muscle of a pregnant uterus. The surface involved in the laceration shows desiccated blood and muscle fibers from exposure, and some minor inflammatory changes in the immediately underlying uterine tissue.

The second section evidently was taken from a location removed from the region of the rupture and shows endometrial tissue with placental syncytial cells.

The structure of the muscle tissue in both sections is of interest; and while presenting the typical characteristics of pregnant uterine muscle, is apparently distinctly abnormal in two features:

1. Many of the muscle fibers show degenerative changes, the cytoplasm being swollen and granular, with loss of many nuclei.
2. A careful estimation of the size of the fibers indicates that they are distinctly smaller in cross-diameter than the normal uterine muscle at term, as determined by measurements made on normal specimens; the average measurements in this case being fifty fibers to the millimeter, while normal specimens averaged twenty-five to thirty fibers to the millimeter.

It is my opinion that this must have been in some degree a pathologic myometrium, but there is no evidence of any local defect at the region of the rupture which was not present throughout the uterus.

COMMENT

In our review of the literature, we find that Estor and Pueck (quoted by Jaroschka) collected forty cases of traumatic rupture of the pregnant uterus up to 1929; to these Orthner adds one case, and our present case makes forty-two in the literature.

One of the reported cases, included in Estor and Pueck's review, that of J. B. DeLee (*American Journal of Obstetrics and Gynecology,* December, 1904), was very similar to our case in the nature of the force, in that his patient also fell through a broken step, striking on her abdomen. It differs, however, in that his patient was a gravida 14 and had had six abortions in the fourth, fifth, sixth, and seventh months, respectively, and therefore probably had a weakened uterine musculature, while our patient was a gravida 1, with no antecedent history, which would indicate probable disease of the uterine musculature.

It also differs from both Orthner's case and our own in that DeLee's case was not seen until some fifty hours after the accident and was operated on sixty hours after the trauma; while Orthner's case was seen and operated on within three hours of the accident, and ours was operated on within five hours of the trauma. As a result the patient reported by DeLee had a very stormy convalescence, but eventually a complete recovery; while Orthner's patient and our patient, who were operated on a few hours after the accident, made smooth, uneventful convalescences, both being discharged from the hospital on the thirteenth postoperative day.

---

* Microscopic report by Dr. N. Evans, hospital pathologist.

This emphasizes the extreme importance of early diagnosis and operative treatment in any case of uterine rupture if our morbidity and mortality (the latter, 100 per cent in cases of complete rupture, unoperated on) are to be kept down.

The question as to whether the laceration should be repaired or a hysterectomy done, depends entirely on the conditions in any given case. As a rule, it would appear to us that a patient in the general condition in which these patients usually are, would be better served by a rapid hysterectomy than by a longer procedure with careful suture of the wound, with the possibility of a postoperative uterine hemorrhage. Moreover, these uteri are usually weakened by antecedent disease, and with the additional weakness of a scar would be particularly susceptible to rupture in a succeeding pregnancy or labor (the latter if section were not done before onset of labor).

However, in a gravida 1, who is desirous of having a child, it would be justifiable if her condition would permit. There have been some cases reported in which repair has been done and the patients successfully carried through a succeeding pregnancy.

In the majority of cases, especially in multiparae, with diseased uteri, we believe hysterectomy, as early as possible, is the procedure of choice.

RECENT CASES IN THE LITERATURE

After this article was written two additional cases appeared in the literature. The first, a report of "Traumatic Rupture of an Early Pregnant Uterus" by G. S. Ruder and C. G. Moore, appeared in the *American Journal of Obstetrics and Gynecology* for March, 1935:

> Their patient, when first seen, was treated for threatened abortion. Eighteen hours later she presented symptoms of uterine rupture, and at operation a complete longitudinal rupture of the uterus, with extrusion of the fetus and placenta into the abdominal cavity, were found. The authors assume that the rupture occurred as a result of an indirect violence, as the patient had been riding on a merry-go-round the day before and they believe that she received a blow upon her side, although she was not aware of it.

Their report does not give any histologic findings such as might indicate preceding disease of the myometrium. . . . Would it not seem more plausible that the ride caused the onset of the abortion and that a weakened diseased uterine musculature gave way, rather than that a longitudinal rupture was caused by a blow which was not sufficient to cause the patient to notice it? Moreover, there were definite signs of a threatened abortion, and the signs of rupture did not occur until some eighteen hours after the onset of labor pains.

The second report, "Spontaneous Rupture of Uterus at Sixth Month of Pregnancy" by F. A. Smilow, appeared in the *American Journal of Obstetrics and Gynecology* for May, 1935:

> Gravida 2. Three hours prior to visit, the patient tripped while ascending stairs. The fall did not hurt her; one hour later she had severe lower abdominal cramps and a slight amount of vaginal bleeding. Vomiting occurred once; eight hours after her visit, a profuse vaginal hemorrhage occurred which left her faint. Two hours later she presented evidence of shock with cold clammy skin. Pulse, 140; blood pressure, 90/60; hemoglobin, 40 per cent; red blood cells, 2,620,000; white blood cells, 16,400; entire abdomen rigid; no definite masses outlined.
>
> At operation, large amount of blood in abdominal cavity, fetus of five months' development in abdomen. Clean, longitudinal rent in midline of the posterior surface of the uterus, extending from the fundus to level of internal os. Placenta densely adherent to anterior wall of uterus. Subtotal hysterectomy done. The patient was discharged from the hospital in two weeks. With the previous pregnancy, she had a toxemia, no convulsions; severe endometritis for several weeks after delivery.

IN CONCLUSION

It is of interest to note that of four cases of rupture of the uterus, the original reports of which we have had access to, three of them, namely, one by J. B. DeLee, one by E. A. Smilow, and our case, the trauma consisted of a fall down the steps.

1930 Wilshire Boulevard.

DISCUSSION

Sterling N. Pierce, M. D. (1930 Wilshire Boulevard, Los Angeles).—At first glance, it is striking that most of the patients reported have survived. However, a reason for the survival is to be found in the fact that the blood vessels constrict, and thus the bleeding rapidly diminishes, or even stops entirely.

The uterine contents (the placenta, the amniotic sac, etc.), are immediately emptied into the abdominal cavity, whereupon the uterus contracts as it would following a section. Since, as is well known, the blood supply at the midline (where the rupture usually occurs) is scanty, these contractions of the uterine muscle practically stop the bleeding.

This consideration would make me believe that in cases where the placenta is inserted more toward the parametrial region, where the contractibility is less and the blood vessels are much larger, the trauma would result in fatal exsanguination.

Concerning the etiology, I would suggest that the weakness at the placental site is to be explained by the fact that the placenta, with its excrescences, digs deep holes into the uterine muscle, so that the muscle is thinned and divided and, with the increased vascularity, is in a condition to tear under impact.

As to therapeutic procedure, I should like to add this comment: much depends on the location of the rupture. If it occurs in the fundus, a repair of the laceration is quick, and is done with less shock. If the tear is located in the lower segment, transverse hysterectomy is indicated.

Palliative measures must be considered and might be life-saving; such as the application of the Momberg belt, or clamping the uterine arteries through the cervix until the patient can be relieved of shock and prepared for surgery.

⁂

J. Morris Slemons, M. D. (523 West Sixth Street, Los Angeles).—Aside from the fact that Doctors Lazard and Kliman have added a case of exceptional interest to obstetrical literature, they have raised questions of considerable scientific importance. It is difficult, for example, to accept the correctness of the hypothesis they adopt. The amniotic fluid, it seems to me, is less likely to promote such an accident than to protect pregnancy against it.

Certainly, the "solid" abdominal viscera, upon occasion, have been ruptured by blows. Accredited instances are at hand of traumatic rupture of the kidney, the liver, and the spleen. The bladder, to be sure, is more likely to be ruptured when full; but is this not partly due to its more exposed position?

A blow upon the abdomen has caused intussusception of the small intestine; and this phenomenon, we are told, may be invoked in the laboratory at will by pinching the bowel of the rabbit with an hemostatic clamp. That experiment, at least, suggests another mechanism as responsible for traumatic uterine rupture. In this particular instance there is evidence of an unusually irritable uterus: the patient was treated previously for threatened premature labor. May not the blow upon the abdomen have excited violent contractions which, in turn, tore open the weak area in the uterine wall? Spastic peristaltic waves have ripped apart an intestinal anastomosis before healing became firm.

This comment merely represents another point of view. At present the true explanation remains beyond us. Perhaps we would approach that objective more nearly if the authors were willing to review cases of rupture of various abdominal organs, attributable to trauma. Such study, almost surely, would repay the time and energy involved.

The treatment responsible for this woman's recovery was that which should always be employed in the circumstances, whether the complication be seen early or late. Otherwise the issue will be fatal.

⁂

Leon J. Tiber, M. D. (3875 Wilshire Boulevard, Los Angeles).—It is surprising that more cases of traumatic rupture of the uterus in advanced pregnancy are not reported, especially considering the tremendous number of automobile accidents.

Is it not possible that in the case of a visible fall, as on some steps, the attempt to break the fall so contorts the uterus that there is a compression area where the uterus is flexed, and, on return to normal, this portion of the uterus presents itself as a weak spot? The authors have pointed out the intra-uterine pressure spreads equally in all directions; therefore, if a rupture is to occur, it should happen at this point of weakness.

It is interesting to note that, in the reported case, there was a demonstrable pathologic variation of the uterine muscular fibers. In the other cases cited it is assumed, from the case histories of previous infections and abortions, that the rupture of the uteri occurred at a pathologic point.

My own experience in the treatment of ruptured pregnant uteri has been with three cases of previous classical cesarean section complicated by hard and neglected labors, none due to accidents. In properly selected cases, one may attempt to repair the tear. However, a subtotal hysterectomy assures a more rapid and safe convalescence. One must always remember that a uterus that ruptured once during pregnancy is certainly more liable to rupture in succeeding pregnancies, other conditions remaining the same. An early diagnosis with active treatment is necessary.

Has there ever been any x-ray diagnosis in these cases—a fluid level of the blood in the peritoneal cavity, an extruded fetus or otherwise irregularity of uterus? These might help to clear up a doubtful diagnosis.

RHINOPHYMA[*]

By Winston C. Crabtree, M.D.
San Diego

Discussion *by Philip K. Allen, M. D., San Diego; F. G. Novy, Jr., M. D., Oakland; K. C. Brandenburg, M. D., Long Beach.*

RHINOPHYMA is a condition perhaps best described by the single term "monstrous hypertrophy of the end of the nose." A fairly accurate clinical picture of the condition is presented by merely listing the descriptive terms often used in naming the disease: whisky nose, nodular nose, copper nose, elephantiasis of the nose, growing nose, acne hyperplastica, fibroma molluscum and cystadenofibroma of the nose.

RHINOPHYMA A DISEASE OF THE SKIN

Rhinophyma being primarily a disease of the skin, probably concerns the dermatologist more directly than the rhinologist. However, inasmuch as the only adequate treatment is surgical, it behooves the rhinologist to familiarize himself with all the phases of this disease in order to be able properly to perform the prescribed surgical measures.

It is at once apparent that the disfigurement and humiliation caused by rhinophyma is of the utmost concern to the person afflicted. In one instance, a case of a woman, the condition caused such extreme personal embarrassment as to result in threatened suicide. Many of the sufferers are led to believe there is no cure for this ugly affliction. That is most unfortunate, because the administration of proper treatment with satisfactory results is rather simple.

With but few exceptions, rhinophyma occurs in the middle or later years of life, by far the greater percentage coming between the ages of fifty and seventy years. It is far more common in the male than in the female, the ratio being approximately twelve to one.

To offer a lengthy discussion as to the etiology of rhinophyma does not fall within the scope of a rhinologist. The condition frequently is considered attributable to chronic alcoholism—at least in the minds of the laity. This common theory is entirely untrue and without foundation. It is perhaps more logical to attribute the chronic alcoholism to rhinophyma than the reverse when the two conditions coexist in the same individual. One author[1] suggests that in many instances there is apparently a congenital predisposition to rhinophyma in the so-called wide-pored individuals. Another states that the nose is the most constantly exposed portion of the entire body, this fact possibly lending to the development and gradual progression of the condition. However, it is generally agreed that the type of tissue present is the etiologic factor of primary importance. That rhinophyma is frequently a sequel or terminal stage of acne rosacea, is an accepted fact borne out by the similarity of the pathologic pictures of the two diseases.

ACNE ROSACEA

Acne rosacea is a subacute or chronic congestive disease of the nose and flush areas of the face. It begins as a passive hyperemia, which is followed later by dilatation and proliferation of the superficial capillaries. Pustules are present. Accompanying the blood-vessel changes is an hypertrophy of varying degree of the cutaneous and subcutaneous tissues. In some instances the hypertrophy may attain a sufficient degree to produce more or less lobulated masses, thus deforming the normal structure of the nose. Also, the pores become patulous and either sebum or pus, or both, may be expressed from them. This stage is known as rhinophyma. Please bear in mind that this process of development is very slow, the progression covering a period of several years, varying from five to twenty.

Histologically, early acne rosacea presents a dilatation of the capillaries with newly formed blood vessels, the increased blood supply resulting in edema and overnourishment of the connective tissues. As the disease advances, deeper vessels

are involved, which may become surrounded in areas by thick mantles of infiltrate made up of lymphocytes, epithelioid cells, and occasional giant cells. The condition being chronic, and one which is prone to recurrences, leads, therefore, to considerable hypertrophy of the connective tissue and sebaceous glands, which together comprise the first signs of the later stage, known as rhinophyma. Rhinophyma, histologically, consists of a marked hyperplasia of sebaceous glands and connective tissue, plus many of the cellular elements found in acne rosacea.

SURGICAL TECHNIQUE

The surgical removal of the large nodular masses is a simple procedure. Correct technique in administering the proper local anesthetic, using two per cent novocain, is accurately described by Labot,[2] the block infiltration being made chiefly along the borders of the nasal pyramid. Using a knife or razor, as preferred, the hypertrophic masses of tissue are readily pared off with exact precision, extreme care being taken to obtain proper reshaping of the nose. Gordon New [3] suggests placing the index finger of the left hand in each nostril as the paring is performed, thus permitting greater accuracy. Rather profuse bleeding is readily controlled by pressure, plus the use of hemostatic solutions, if such are desired.

Considerable emphasis should be placed on the importance of not shaving too deeply, and for two reasons: first, to avoid injury to the nasal cartilages, and, second, to preserve a thin layer of subcutaneous tissue and many islets of epithelial tissue, which are necessary for proper epithelization. These small islets of epithelial tissue are from the sebaceous gland rests, and are plainly visible as the surgery is performed if time is taken to slow the bleeding. It is also important to preserve a thin rim of epithelium around the nares in order to prevent disfigurement from resultant contractions incident to cicatrization. Vaselin gauze, hot compresses or xeroform gauze dressings are to be used with tinfoil or a thin cast of dental wax, necessary for holding the dressings in snug position over the nose.

Healing with proper epithelization will generally occur with rather amazing rapidity. Dressings may be omitted after seven to ten days as a rule. The use of tincture of benzoin, 25 per cent silver nitrate, trichloracetic acid, and scarlet-red ointment, are all commendable for use postoperatively in dealing with granulation and scar tissues. One dermatologist [4] recommends x-ray and sometimes carbon dioxid snow for postoperative treatment if granulations or scarring are in excess.

OTHER PROCEDURES

Treatment of rhinophyma by galvanocautery or electrocoagulation should be rejected as unreliable and dangerous, because of possible damage to underlying bone, cartilage, and nasal mucous membranes.[5] The extent of the necrosis which may follow use of the cautery cannot be accurately gauged at the time of operation. Also there may result an extensive destruction to the epithelial tissue, which must be preserved to obtain a proper and prompt healing. Electrocoagulation has been suggested by some men as useful during [6] the operation for hemostasis.

The literature of several years ago will reveal frequent descriptions of the use of skin flaps from the forehead, or grafts from the arm, as necessary in procuring the proper cosmetic end-result in the treatment of rhinophyma. Such measures have been almost entirely discarded. The use of the graft is now confined only to cases of rhinophyma with carcinomatous degeneration, or in instances where x-ray, radium, or cautery have been employed inadvertently, with a resultant destruction of too much of the nasal tissues.

X-ray therapy is commonly employed by the dermatologist in treating acne rosacea. Thus it follows that the use of x-ray in treating rhinophyma may be of value particularly in diminishing the folliculitis, which may often be severe. Such a procedure is frequently very useful as a preoperative measure in better preparing the case for surgery, whereby sometimes 30 to 40 per cent involution of the tumor mass may be obtained.[7] In mildly developed rhinophyma, the use of x-ray therapy in clearing the folliculitis may allay or even entirely remove the necessity for surgical treatment. Radium, likewise, has its place in similar therapy. This phase of the treatment of rhinophyma is, of course, to be placed in the hands of the dermatologist. Thus, stress should be placed on the complete coöperation between dermatologist and rhinologist in procuring the best results.

IN CONCLUSION

In concluding, the following points demand emphasis:

1. The actual causative etiology of rhinophyma is somewhat obscure, though the condition is recognized as a benign sequel of acne rosacea.
2. Adequate surgical treatment of rhinophyma is a relatively simple procedure.
3. The use of skin grafts, cautery, and electrocoagulation have been, in the main, discarded.
4. X-ray is very valuable in both pre- and postoperative treatment, and in some instances may be sufficient treatment, to the point of excluding surgery.
5. Full coöperation between dermatologist and rhinologist is essential in all cases of rhinophyma.

DISCUSSION

Philip K. Allen, M. D. (314 Medico-Dental Building, San Diego).—I am most interested in this paper from a standpoint of therapy, particularly the cosmetic end-result. Inasmuch as rhinophyma does not endanger life nor impair health, the appearance is of prime importance. The condition is by no means a new one. It was known to Hippocrates and was described by the early Arabians. In more than two thousand years innumerable types of treatment have been advocated, most of them without real therapeutic value.

The nonsurgical treatment of rhinophyma has proved unsatisfactory. Local applications which are not caustic nor destructive may impede the progress of the disease, but do not reduce the hypertrophy. X-ray and radium therapy have, on the whole, proved disappointing, although occasionally pleasing results have been reported. McKee states in his book, "X-Ray and Radium in the Treatment of Diseases of the Skin": "X-ray (and radium) seem to be of very little real service in rhinophyma." Acne-like lesions do disappear under x-ray treatment, and the sebaceous glands will become smaller and less active. In a markedly enlarged nose, however, the limited shrinkage that can be effected by x-ray does not give satisfactory end-result. Its usefulness is limited, therefore, to the early case in preventing further hypertrophy. Where considerable enlargement has taken place other forms of treatment, mainly surgical, are indicated.

Various types of surgical measures have been used. Acids, caustics, cautery, and scarification have all had advocates. It seems odd that the simple and most obvious procedure of carving the nose down to the desired size and shape should be left to comparatively recent times.

The good results in such a simple sculptural operation are due to the anatomy of the condition. Removal of hypertrophic tissue leaves sufficient basal epidermal cells to insure rapid and complete epithelialization.

I agree with the essayist that the best cosmetic results are to be obtained by surgical excision of the hypertrophic tissue; but I would suggest, as an aid to prevent subsequent regrowth, the use of the x-ray as soon as epithelial regeneration has taken place.

* * *

F. G. Novy, Jr., M. D. (411 Thirtieth Street, Oakland). Doctor Crabtree should be commended on emphasizing the simplicity of the surgical treatment of rhinophyma. The use of skin grafts and complicated surgical procedures are unnecessary, as epithelialization takes place rapidly from the remains of the sebaceous glands.

I do not agree with the author regarding the use of electrodesiccation. If this modality is used with a low current and care, good results may be obtained. Klauder (Arch. Dermat and Syph., 33:885, May, 1936), recently reported a satisfactory technique. He inserts the electrodesiccating needle (unipolar method) into the mass, and a low current is then turned on until a small area is blanched. This is then curetted until bleeding occurs, when another area is treated or the same area is again treated if further destruction is desirable. The advantages of this method are that the operation is nearly bloodless and the cosmetic result compares favorably with surgical excision.

* * *

K. C. Brandenburg, M. D. (110 Pine Avenue, Long Beach).—We are indebted to Doctor Crabtree for presenting us with a simple but effective remedy for a most disfiguring condition which, though it does not endanger life, may render existence extremely unpleasant to the individual suffering from this hideous deformity of the nose.

It is surprising that the ingenious expedient of shaving off the redundancy has not been resorted to before; but, as with so many other simple procedures, we must be shown by someone with Doctor Crabtree's courage and good sense.

The importance of rehabilitating these individuals is much greater than anyone who has not suffered from such a disfiguring condition can realize. As is also the case with crossed eyes, these unfortunate individuals are frequently highly sensitive about the matter and find it a marked social disability.

The knowledge that an effective treatment is available will be most welcome to wearers of "whisky noses."

SCABICIDAL DRUGS: AN EXPERIMENTAL STUDY*

By H. J. Templeton, M.D.
and
H. V. Allington, M.D.
Oakland

Discussion *by George V. Kulchar, M. D., San Francisco; Hiram E. Miller, H. D., San Francisco; Samuel Ayres, Jr., M. D., Los Angeles.*

Scabies is a disease whose treatment we generally approach quite confidently, feeling that we have in sulphur a near-specific which, in the great majority of cases, is rapidly curative. However, we have all had the experience of treating patients whose scabies was cured only with great difficulty, even though not complicated by irritation from the sulphur and though the balance of the family were properly treated and the clothing adequately sterilized. Such experiences have modified, to a certain extent, our former cocksure attitude in regard to the ease of curability of this disease.

KINGSTON'S STUDIES

This attitude was intensified, and the present experimental work stimulated by an interesting

[6] Upsher Smith.

article by Kingston[1] entitled "An Outbreak of Scabies in a Mental Hospital." Using an apparently adequate and careful technique of treating scabies by means of Sulphur Ointment B. P., he came to certain discouraging conclusions, which I will quote:

> Out of ten certain cases of scabies in mental patients, not one was cured by two courses of sulphur ointment treatment. A total of thirty-three courses of treatment resulted in five cures and five failures.

Kingston then performed some interesting experiments testing the scabicidal powers of various antiscabetic remedies. He dug out of patients burrows, active living female acari, and imbedded them in different remedies. These acari were then observed under the microscope until all movements of extremities and viscera had ceased, which point was taken to indicate death. His results are given in Chart 1.

AUTHORS' STUDIES

Inasmuch as Kingston did not study many of the scabicidal remedies in use in this country, we have performed similar experiments with different preparations.

Our method of procedure consisted of removing acari from the burrows of untreated patients, and imbedding four to eight lively specimens under a cover glass in each remedy to be studied. These were observed microscopically until all movements ceased. The survival times are indicated in Table 1.

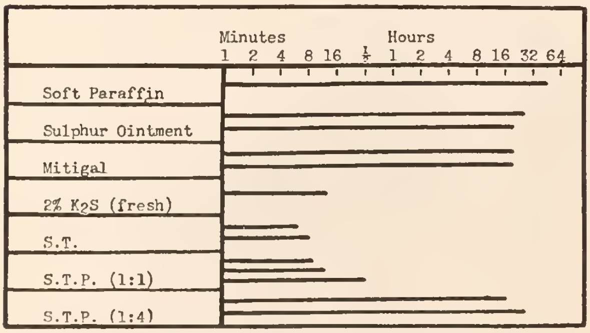

Chart 1.—(After Kingston.) Survival times of sarcoptes in various media (logarithmic scale). S. T. 1 per cent solution of sulphur in oil of turpentine B. P. S. T. P. (1:1) equal parts of S. T. and liquid paraffin B. P. S. T. P. (1:4) one part of S. T. to four parts of liquid paraffin B. P.

We are perfectly aware that the scabicidal property of any drug *in vitro* does not necessarily parallel its clinical value. The discrepancy between the proved clinical worth of sulphur and its slow killing time in our experiments might be explained by the theory that it is changed to the nascent state by the acids of the skin when it is applied to a patient. This could not hold true, however, of all of the other drugs studied. Therefore, it is our belief that the method of determining the scabicidal power of drugs *in vitro* is of practical value, and merits further attention in the search for more effective remedies.

DISCUSSION

GEORGE V. KULCHAR, M. D. (450 Sutter Street, San Francisco).—The evaluation of scabeticidal preparations by clinical methods is not entirely satisfactory, and for several reasons. Patients frequently do not carry out the routine properly, particularly in regard to sterilizing their wearing apparel, bed linen, and so forth, and reinfections are seen commonly. The thoroughness with which the patient applies the preparation and the thickness of the epidermis seem to be factors in the therapeutic efficiency of the commonly used scabeticides. To a certain extent one can prove the efficiency of a scabeticidal preparation by recovering the acari from lesions and determining, by microscopic examination, whether they are dead. At the same time, however, if one searches diligently in a patient who gives the clinical impression of being cured, an occasional live acarus can be recovered. The method proposed by Doctor Templeton certainly provides a more accurate means of evaluating scabeticidal preparations.

⁂

HIRAM E. MILLER, M. D. (384 Post Street, San Francisco).—The authors' experiments with various antiscabetic remedies are most interesting. Their experimental results, however, do not coincide with clinical experience. It is well known, as they state, that sulphur is chemically changed when it comes in contact with the skin, and its efficacy in destroying the acarus of scabies is probably greatly enhanced by this change. Ringworm fungus will thrive on a culture media containing three per cent sulphur, but tinea circinata can generally be easily cured with a three per cent sulphur ointment. These experimental results would erroneously infer that one per cent creolin is much superior to sulphur in the treatment of scabies. I should have thought that petrolatum would mechanically destroy the acarus in a very short period of time.

This work is most instructive and worth while, and I am certain that the authors are fully cognizant of all the points that I have mentioned.

⁂

SAMUEL AYRES, JR., M. D. (2007 Wilshire Boulevard, Los Angeles).—As Doctors Templeton and Allington have stated, the problem of treating scabies is by no means a closed chapter, and they have offered us a rational method for improving our therapy of this common and occasionally obstinate disease. We have never depended upon sulphur ointment alone, but have employed the formula long in use at the Massachusetts General Hospital:

Betanaphthol	2
Sublimed sulphur	4
Balsam Peru	15
Petrolatum	15

It is interesting to note, from the table presented, that both betanaphthol and balsam Peru in concentrations much less than employed in this formula are among the most active scabicidal drugs tested. In this case the experimental findings confirm our clinical experience of the remarkable efficacy of this particular combination of substances. By further experimentation along the lines suggested by the authors of this paper, however, it is entirely reasonable to assume that a more efficacious and less irritating remedy will be found.

URINARY TRACT INFECTION WITH "CLEAR URINE" *

By James R. Dillon, M.D.
San Francisco

Discussion *by Robert V. Day, M.D., Los Angeles; F. S. Dillingham, M.D., Los Angeles; Charles P. Mathé, M.D., San Francisco.*

It is surprising how many times medical men fail to recognize urinary tract infection in fairly typical clinical pictures because there is no pus in the urine, which may be macroscopically clear. This occurs particularly in both the acute and chronic coccal kidney infections, where the microscopic examination of the urine may show only a few red cells, few or no pus cells, and by the ordinary routine bacteriologic examination, few or no cocci. The urine in acute bacillary infections is practically always cloudy macroscopically, but microscopically may show only a few or no pus cells; the cloudiness being due to bacilli only, which is often considered a contamination, and the patient is treated as a "flu" condition, or possibly extensive examinations are carried out to differentiate typhoid, malaria, and other infective conditions, with a neglect of the urinary tract. Chronic bacillary infections also frequently occur with macroscopically clear urines which reveal no pus microscopically, and few or no bacilli are reported by the bacteriologist. This report is presented for the consideration of the diagnosis and etiology of various clinical pictures rather than treatment, it being evident from the histories of patients of repeated urologic examinations that diagnosis in this type of case is frequently missed by the urologists as well as internists. Nor does it include the cortical renal lesions or the so-called carbuncle of the kidney; nor the perirenal abscess types.

About fourteen years ago my attention was first attracted to the possibility that sometimes bacteria appear in the urine in "showers" during the acute stage, which may last only a few hours, and with three or four voidings the urine may be entirely clear of pus and with relatively few or no bacteria present.

REPORT OF CASE

Case 1.—A medical woman, actively practicing with her husband, also a medical graduate, complained of a pain in her right side, ran a low-grade temperature, rarely reaching 100 degrees, except during the acute attacks. The pain and tenderness seemed to be definitely in her right kidney, but cystoscopic examination and pyelograms by three different urologists, over a period of one year, showed normal pyelograms and negative urine reports from the bacteriological laboratories. One of the urologists passed four catheters up the right ureter, three of them stopping just below the pelvic brim at the site of an apparent ureteral stone shown in the x-ray, but at surgery this proved to be a phlebolith, and she continued to have her attacks. She resided about one hundred miles from San Francisco, and would have an attack (at intervals from two to six weeks) of rise in temperature, increased pain and tenderness, burning and frequency of urination. Samples of the urine during this onset would be loaded with pus and colon bacilli. She would start by automobile with the onset of the attack, and by the time she reached my office, in about three and one-half hours, voiding three or four times on the way, a catheterized specimen would be crystal-clear and the bacteriological laboratory report would be negative. On the eighth trip pus and colon bacilli were found in a catheterized specimen, and an immediate cystoscopic examination and collection of segregated urines showed the left kidney sterile and the infection entirely in the right kidney. Her tonsils had been removed and all possible foci checked by myself, as well as the two preceding urologists. Doctor Rigdon had been in consultation several times, and we finally decided it was a blind abscess in the renal cortex, which at times discharged into the renal pelvis. At operation we thoroughly exposed the kidney, pelvis, upper end of the ureter pedicle, and finally did a nephrotomy, exposing the pelvis from pole to pole. Cultures taken of the urine in the pelvis, on opening it, and sections of renal parenchyma were negative for signs of infection or pathology. She made an uneventful recovery, but I carried a guilty conscience until I met her several years afterward and she thanked me again, stating she had never had another attack after the operation.

OTHER TYPES

Cases of urethritis in males with coccal infections, showing a very slight purulent or mucopurulent discharge, or merely a glueing of the meatus in the morning, are sometimes treated over an indefinite period as a chronic gonorrhea or gleet. The two- or three-glass test may show all crystal-clear, with the first glass containing a few shreds, or possibly presenting a faint haze. The bacteriologic report of the second or third glass, as ordinarily done, will generally be negative, few or no pus cells, few or no red cells, or a few described bacteria, either coccal or bacilli, and if there is a scanty growth on the cultures, the opinion will be expressed "probably contamination," and the patient goes on being treated as an urethritis. I have had bacteriologists make the statement to me, when their cultures are slightly positive, that they were probably contaminations because the smears of the sediment did not show any pus. Men will also frequently appear complaining of frequency of urination, with slight bladder-neck sensitiveness or consciousness, revealing a macroscopically clear urine with a negative pus and bacteriologic report, and if the patient has no chronic prostatitis, he is lucky if he does not have one immediately made by repeated massaging. Or, if he is fortunate in having his prostate acquitted at the first trial, he may be retried and condemned as a neurotic. These bladder-neck irritabilities occur in both men and women, who suffer for indefinite periods because a diagnosis and cause is not ascertained. There are other clinical pictures appearing as a septic condition, with no symptoms referable to the urinary tract, and presenting macroscopically clear urine.

---

* Read before the Urology Section of the California Medical Association at the sixty-fifth annual session, Coronado, May 25-28, 1936.

BACTERIOLOGIC LABORATORY: ITS PLACE

In recent years I have come to depend less on the professional bacteriologic laboratories for my urine examinations, especially in the case of the ambulatory patient who comes to my office. Practically all of such reports are based on the smears and cultures made from the sediment of one centrifuge tube of urine. If the infective products are sufficiently diluted in the urine that it is macroscopically clear, those products will be very likely missed in the study of the centrifuged sediment of one tube of urine. I have trained my office nurse to concentrate the sediment of the entire collection of catheterized urine in the female and the third glass of voided urine in the male until she can plainly see a film of sediment in the bottom of the centrifuge tube. This is done by filling the centrifuge tube, vigorously centrifuging it and pouring off the supernatant urine and refilling it. This is repeated until the sediment of the entire specimen, amounting to six or eight ounces, as a rule, is concentrated in one tube. The supernatant urine from the last filling is poured off quickly, holding the tube in an inverted position until the smear is made from the scrapings from the bottom of the tube. The smears are fixed and stained with 1 per cent methylene blue, and for most cases we are only interested at this time in whether infection is present and whether it is coccal or bacillary. If present, it is then incumbent upon us to not only make a further urologic study by intravenous urography, cystoscopy, and possibly retrograde pyelograms, but also to determine the etiologic factor and its removal. Women frequently will be apparently cured of an urinary-tract infection, and the urine may be reported free of pus and bacteria, but they may continue to complain of bladder irritability, frequency, and urgency. Cystoscopic examination will reveal a normal-appearing bladder, but the distal side of the vesical orifice will show an inflammatory condition of the urethral mucosa, or, if of long standing, may show a fringe of polypi.

RÔLE OF ALVEOLAR INFECTIONS

My personal opinion is that infection and absorption of the alveolar process is the source of most of our upper urinary tract infections. I try to avoid the term "infected teeth," which is a dental problem, but an infected alveolar process, signifying really an osteomyelitis, is a medical and surgical problem, and we must seek those dentists who recognize this fact to coöperate with us in the proper surgical treatment. We must train ourselves in the study of x-ray dentures, insist on inspecting them ourselves, and follow up with further x-ray studies in three to six months' intervals to see that pathologic conditions in the alveolar process have really cleared up, before we are qualified to challenge the statements of those who are experienced in this study and believe such foci to be causative factors. Our search for foci should not end here, but all possible primary areas of infection, such as tonsils, sinuses, middle ear, skin, bowel, rectal and genital, etc., should be eliminated. Also, there is evidence that the primary infection of the kidneys may be very transient, clearing up spontaneously where the ureteral drainage is adequate; but it may then continue indefinitely as a trigonitis and urethritis, and serve as a focus for blood-stream or lymph-stream dissemination, or direct ascent by the ureter, and so produce recurring attacks of pyelonephritis after the primary focus has been removed.

The following are a few case histories illustrating the various clinical pictures of "clear urine" with urinary tract infection:

REPORT OF CASES

Case 2.—A husky Danish ambulatory longshoreman complained of frequency of urination with occasional urgency. Examination negative, except for the concentrated sediment of a "clear urine" showing a streptococcus, later confirmed by the bacteriologist as Streptococcus viridans. He would be temporarily relieved by bladder irrigations and urinary antiseptics, and was finally completely cleared up after several recurrences by getting a marked pyorrhea properly treated.

* * *

Case 3.—A ten-year-old school boy (one of four in the last year) complained of urgency, frequency, and feeling tired. Urine was clear, but showed trace of albumen, occasional casts and red cells, and the concentrated sediment showed a streptococcus, also confirmed by the bacteriologist. Cystoscopic examination and pyelograms were negative. He was put on urinary antiseptics, and a week later complained of a "gum boil." With the removal of a deciduous tooth, his urinary tract spontaneously cleared of albumen, blood, and streptococci.

* * *

Case 4.—A fifteen-year-old girl (the daughter of a medical man), strong, athletic, ambitious, but all her life had been subject to attacks of chills, fever, and prostration, every two or three months. She had been examined by internists, until one discovered she had a "floating right kidney" and suggested a cystoscopic examination, which disclosed a catheterized urine free of pus, but hazy with colon bacilli coming from the dilated functionless left half of a "horseshoe kidney." She was cured by nephrectomy.

* * *

Case 5.—A Jewish woman, age sixty-five, complained of frequency and urgency; also had a great liking for "sprees" on barbital drugs. She had been pronounced cured of a urinary-tract infection, but continued to suffer bladder symptoms for many months and was treated more as a mental case. Examination of the concentrated sediment of a catheterized specimen of "clear urine" showed a trace of pus and a fair smear of colon bacilli. Cystoscopic examination showed normal kidneys, but a fringe of polypi on the urethral edge of the bladder neck. Removal of all her remaining teeth, about ten, around which there was marked pyorrhea, fulguration of the polypi, followed by a few urethral dilatations and bladder irrigations with urinary antiseptics, cleared up the urinary tract entirely.

* * *

Case 6.—A young Italian, age twenty-one, presented an acute septic condition, temperature 104 degrees, with pain in the right side, diagnosed appendicitis. A normal appendix was removed, but the septic condition continued for four months, with symptoms apparently localizing in the right kidney. Absolutely clear urine persisted throughout the entire course, except on one occasion, when a Streptococcus hemolyticus was obtained. A diagnosis was made by the urologist, from the pyelogram and intravenous urogram, of a Streptococcus cellulitis around the middle calyx of the right kidney. Through lack of coöperation, an x-ray denture was not obtained until he developed a toothache at the end of the four months of septic temperature, disclosing an abscess on the root of another tooth, on the extraction of which his temperature dropped to normal within forty-eight hours, where it has since remained.

Case 7.—A woman, twenty-nine years old, complained of urgency and frequency shortly after the onset of a crop of boils on the buttocks. The concentrated sediment of a "clear urine" showed a good smear of staphylococci with no pus. It cleared up with bladder irrigations and urinary antiseptics along with the disappearance of the boils. Three years later she again had the same bladder symptoms, with staphylococci in a "clear urine." This time she complained of pain and soreness in the rectum, and on the removal of an anal fissure and a rectal cryptitis by a proctologist, her attending nurse volunteered the statement that her bladder capacity had increased from five to twelve ounces within forty-eight hours, and along with the urinary antiseptics and bladder irrigations her urine is again sterile.

CONCLUSIONS

1. Foci of infection play an important part in the causation of urinary tract infections.

2. In vague septic conditions more attention must be paid the urinary tract as a possible location of infection, in spite of the negative clinical examination of the urine.

3. Dentists should be taught to recognize more of the medical and surgical aspects of an infected alveolar process.

4. Before condemning patients with bladder symptoms with "clear urine" as neurotics, we should send larger quantities of bladder urine to the bacteriologist with the request that the examination be made on the concentrated sediment of the entire specimen.

5. Children should be watched more closely during the tooth-cutting age, and attention given to dental care and hygiene. Also, during the septic reactions, the urinary tract should not be forgotten, and more exacting examinations should be made for the presence of bacteria in the "clear urine."

490 Post Street.

DISCUSSION

Robert V. Day, M. D. (1930 Wilshire Boulevard, Los Angeles).—Doctor Dillon has brought to our attention some particular phases of urinary infections which are often overlooked.

I should like to emphasize his meaning by using the term "seemingly clear," or "nearly clear urine." In such cases the specimen is apt to be of low specific gravity and, hence, exceedingly diluted. By greatly restricting the intake of fluids for twelve hours, one can frequently obtain a urine of a specific gravity of 1.020 or so, in which case the amount of pus is usually sufficient to show cloudiness to the naked eye except in those cases where only a few bacteria are present in the urine. These cases are often very baffling until observed over a considerable period of time.

Our first duty is to determine the presence or absence of infection by repeated urine examinations and, if present, to identify the organism responsible for the infection. For this purpose, both stained smears (preferably a Gram stain) and cultures are invaluable.

If urinary infection is demonstrated, then one may proceed methodically to discover each and every anatomical focus of infection by cystoscopic and other recognized urologic procedures.

*

F. S. Dillingham, M. D. (1016 Story Building, Los Angeles).—In the past a great deal of thought has been given to pyelonephritis, and today Doctor Dillon has called our attention to a phase which, kept in mind, may save a long course of illness by promptly leading to the correct diagnosis. In 1916 Crabtree and others noted that, early in an attack of pyelonephritis, there may be a great drop in phthalein output due to a cloudy swelling, probably involving the tubular portion which is short-lived, and which goes on to complete recovery, as shown by the return of kidney function and even on microscopic sections.

It may be our misfortune to see these patients only in the intervals as in the case of the doctor's wife, who was only three and a half hours away, and not until the eighth examination were bacteria found. Is it possible that in Doctor Dillon's extensive exploration of this patient's kidney some minor kink was relieved, or nerves or lymphatics cut that resulted in freedom from attacks?

When the specimen is macroscopically clear in a suspected patient, Doctor Dillon's suggestion of concentrating the smear to be examined is as important as running the centrifuge at high speed for a longer interval when searching for tubercle bacilli. Also, the freshness of the urine specimen is of importance, as many come with specimens twenty-four to forty-eight hours old, in questionable containers, that are macroscopically cloudy, and yet after proper cleansing a fresh specimen is found to be free of pus, blood or bacteria.

In 1917, E. H. Stephens stated that simple bacilluria may exist without cells in the urine. Livermore found stasis to be the chief cause of renal infection; as there may be foci, but without stasis, there will be no infection unless there is an overwhelming amount of bacteria. Rovsing found that infection could not be caused without retention or trauma.

In 1916, Eisendrath and Kahn found that infection travels from the bladder to the kidney and perinephritic tissue by way of the lymphatics in the wall of the ureter and not along its mucous membrane. The lymphatic capillaries of the periureteral sheath play a most important part in ascending infection. Franke found that the lymphatics of the ascending colon communicate with those of the right kidney. Cystitis and renal infections following gynecologic operations take place by way of the lymphatics. With care not to cause trauma, emulsions of bacteria were injected into the bladder; (Bacillus coli, Staphylococcus aureus, Proteus vulgaris, gonorrheal pus). Inflammatory infiltrations followed the course of the lymphatics, beginning in the submucous layer of the bladder, especially around the smaller blood vessels in this layer, and this holds true for the lower ureter. Higher along the ureter, in addition to the submucous infiltration, there is infiltration around and in the walls of the blood vessels of the periureteral sheath. Later the other coats become invaded from without inward, the mucosa remaining intact until the infection is well advanced. In the kidney pelvis, the infiltration is seen first in the subpelvic areolar tissue, and again around the blood vessels, the overlying mucous membrane remaining intact. In the kidney the infiltration is seen first around the renal vessels which pass into the parenchyma. In the cortex, between the tubules and around the glomeruli, and as the infection advances, the medulla is invaded in the same intertubular manner, and finally infiltration breaks into the lumen of the tubule. The infiltration follows closely the lymphatics which allow of communication between the cortex and those penetrating the true capsule which, in turn, communicate with the perinephritic tissue. They are convinced, as Bauereisen and others assert, that there is free communication between the lymphatics of the bladder and of the ureter, and that the lymph current is upward. The connecting link between the lower ureter and those within the kidney is along the lymphatics of the subpelvic areolar tissue which surrounds the blood vessels as they enter the kidney tissue. In none of the laboratory animals were the bacilli recovered from the heart's blood. Lymphatics of the lower genito-urinary tract, David MacKensie and A. B. Wallace (*Journal of Urology*) conclude: "Dye injected in small quantities in rabbits to different areas of the bladder wall, different levels of the ureteral wall and cervix, is absorbed and passes to the common iliac group of glands, either directly or through interposed smaller nodes, then upward toward the thoracic duct, and the implication from one series was that the dye passes to the blood stream and to the kidney."

Examine neurotics with special care. The term usually covers the fact that a correct diagnosis has not been made, not only in the strong longshoreman or ambitious young person types, but also in weak nervous patients suffering from chronic absorption from undiagnosed foci as have been mentioned, and stasis in the intestinal as well as the urinary tract. We cannot always get a perfect history, as one woman whose symptoms were unquestionably pyelonephritis with a severe cystitis, but whose upper urinary tract on repeated examination was found negative. Later it was brought out that a bilateral pyosalpingectomy had been performed, and due to the resultant adhesions there was direct infection of the bladder, causing the severe cystic symptoms.

Chronic seminal vesiculitis has been another source not mentioned by the author, and has caused acute attacks so severe that more than one patient has had an emergency appendectomy performed. One of our own patients, a boy of nineteen (with no symptoms referred to the kidney, ureter or bladder), complained of an acute, mild, nonspecific urethritis, which would clear up with a few days' treatment, only to recur. After a month or so he voided a small ureteral calculus, when all of his symptoms were relieved. This emphasizes the necessity of a careful history and a thorough urologic study, even in those patients in which the causes may seem very simple. Red blood cells found in the urine and not accounted for should call for an examination, including intravenous urography and, if warranted, followed by a retrograde x-ray study.

In 1927 Eisendrath made a plea for the early use of the indwelling catheter, but each patient must be handled individually, because there are some acute cases in which lavage and catheter drainage aggravate the condition; and yet the same measures during another attack may act like a charm. (Hooe left a catheter in one kidney eight days and in the opposite kidney fourteen days, with no untoward results.)

Modern treatment of pyelonephritis should include the stimulation of the endocrines that have to do with infections.

Doctor Dillon has called our attention to a condition which we may meet clinically daily, and yet about which very little has been written or said.

⁂

Charles P. Mathé, M. D. (450 Sutter Street, San Francisco).—Doctor Dillon has presented a paper in which he stresses the point that many infections of the urinary tract are overlooked because of inadequate examination of the urine. In cases in which pyelonephritis is suspected, and in which the urine is found to be clear, repeated examinations of catheterized specimens should be made because pus and bacteria might occur in showers. However, if one takes the care to make these repeated examinations he will usually encounter pus and the infecting organism. Occasionally pus and organisms fail to find their way into the bladder because of some obstructive lesion in the ureter such as a stricture or edema. In these a complete cystoscopic examination is necessary to establish a diagnosis.

When one encounters polypi on the neck of the bladder and in the posterior urethra, one should look for infection in the prostate gland and in the kidneys. These are often secondary to kidney infections, and this phenomena is often observed in the female.

The rôle of foci of infection in the production of chronic pyelonephritis has long been recognized, but not sufficiently emphasized. Years ago Rosenow, and Bumpus and Meisser demonstrated that the green-producing streptococci, originating in foci such as teeth and tonsils, have a specific predilection for the kidneys. In all cases of chronic infection, abscessed and pulpless teeth, and infected tonsils should be removed. Unfortunately, in many cases these are removed too late, when irreparable damage to the kidneys had already taken place. We have observed that, following removal of these primary foci, a severe general reaction may follow which might be accompanied by an exacerbation of pyelonephritis. This phenomena may be considered as positive evidence of the original infective focus. Modern treatment of chronic pyelonephritis should consist of systematic eradication of other possible foci, as well as infections of the skin, prostate, seminal vesicles, sinus, ear, etc. Chronic constipation and stasis in the upper and lower urinary tract should also be corrected, as these play an important rôle in the production of chronic pyelonephritis.

I recall a patient possessing a huge pyohydronephrosis presenting chronic pyuria which had been treated for chronic prostatitis for two years by a competent urologist. Because of pain in the upper abdomen, a surgeon diagnosed chronic colitis; however, on encountering a mass in the right upper abdomen, he suspected a kidney lesion and referred him to me for examination. A complete urologic study revealed a huge infected hydronephrosis secondary to an aberrant vessel, and nephrectomy cured the patient of his pyuria. I observed a similar patient presenting calculus pynephrosis who had been treated for chronic prostatitis in one of our clinics for seven years. These experiences should emphasize the importance of making a complete urologic investigation in all cases presenting chronic pyuria.

The internist and general surgeon often confuse pyelonephritis with influenza, abdominal lesions such as appendicitis salpingitis, gall-bladder disease, gastro-intestinal lesions, etc. As Doctor Dillon has so well pointed out, the distinguishing feature in its differentiation lies in painstaking, repeated urine analyses, including centrifugalization of the urine over a long period of time, and making careful cultures.

THE LURE OF MEDICAL HISTORY†

THE HUNTERS IN EMBRYOLOGY*

By A. W. Meyer, M.D.
Stanford University

II**

In addition to many fine representations of the pregnant uterus, this costly volume of William Hunter's contains drawings of dissections of the latter, and representations of the ovaries and of placentæ injected with colored wax from the uterine and umbilical vessels. Although it was the dissection and study of a doubly injected uterus, with the injected fetus *in loco*, that convinced John of the independence of the maternal and fetal circulations, the relationship of these circulations is left without comment in William's famous treatise. It is true that William referred to "RR" as "Veins emerging from the substance ot the placenta and broken through at its surface, where they were passing into the womb" in connection with Plate 19, and that he said in connection with Figure II, Plate 24: "Most of the blue wax, which was first injected by the veins of the womb, was driven on towards the internal surface; and the red wax, which was afterwards injected by the arteries, was lodged principally in the outer parts; but the two colours were, more or less, blended through the whole." In one of the legends accompanying Plate 5, he spoke of "ee" as "injected veins, of a flattened figure with numerous anastomoses, passing from the womb to the placenta in a very slanting direction." "LL" of Figure 1 of Plate 24 is of "The placenta, adhering to the womb. None of the wax, injected into the vessels of the womb, had passed into the branches of those vessels which compose the navel-string; . . . but the cells, or interstices in the spungy part of the placenta, were universally loaded with wax, either the blue, which was injected into the veins of the womb, or the red, which was thrown into the arteries." In connection with "BBB," Figure 1, Plate 29, he said: "The round surface, enclosed by that edge, is the outer surface of the placenta, which had adhered to the womb. In separating those two parts, many arteries and veins were torn through, one part of each remaining with the womb, and the other with the placenta."

ON THE INDEPENDENCE OF THE FETAL AND MATERNAL CIRCULATIONS

Although these words leave the crucial conclusion to the insight and inference of the reader, it may be recalled that William said that his "discovery" of the independence of the fetal and maternal circulations had been acknowledged by Haller thirteen or fourteen years before the disagreement with his brother John in 1780, in Haller's *Elementa physiologiæ corporis humani,* Vol. 8, p. 220, which appeared in 1766. However, instead of having credited William with the discovery, Haller[17] merely gave a brief summary of William's ideas in an addendum, retaining the contrary idea in the text and saying that Hunter's ideas regarding the decidua have been "partly corrected and partly confirmed." According to Haller's statement in this addendum, William believed that a liquid injected into the vessels of the uterus "pours into every cellular part of the placenta, and from these cells returns into the broader veins of the uterus. None of it passes into the branches of the umbilical vessels. When the umbilical artery is filled with a colored liquid, while the placenta still adheres to the uterus, the branches of the umbilical arteries and veins are all completely and readily filled; yet nothing passes into the vessels of the uterus, unless the liquid has poured into the cells of the placenta." Haller hence merely stated that William believed that the two circulations were independent without characterizing the idea as a discovery. Since this was written in connection with a historical summary of the idea, it is not without significance.

Teacher[9] (1900) concluded that ". . . it is unreasonable to suppose that they [the injections] were figured then [1750], yet only understood in 1754." (p. lvi.) But it seems equally strange that William should have remained silent in 1774 in regard to what he said, in 1780, he so firmly believed and thought he had discovered in 1754. I do not know upon what grounds Teacher[18] (1899) stated that William's conclusion regarding the distinctness of the maternal and fetal circulations "was, as Hunter was aware, strictly speaking, not a new discovery" (p. 32), but if justified, it robs William of his claim and reveals him in disparaging light. It may well be true, as Teacher held, that William Hunter presented the anatomical proof that the two circulations do not mingle, yet the real question is not whether he presented this proof, but whether he fully accepted it for man, before John, and that does not seem to have been the case. This point is referred to by an anonymous auditor[14] of William's lectures who recorded him as saying that

> These appearances I first saw in a cat that was pregnant which I injected from the uterine vessels, after which I injected by the navel string. The injection was distinct, I afterwards saw the same in a bitch. These discoveries were early in life, and taught me to believe that the same course of things existed in the human species, though I could not demonstrate it, not having had an opportunity to inject a pregnant uterus; but soon after I did meet an opportunity, & the appearances staggered me. For after injection of the parts, I found the uterine injection filled up a great part of the placenta &c. which on examination proved to be spongy & cellular. (p. 82.)

Hunter no doubt was "staggered," as well he might have been, because the injections of pregnant human uteri, instead of being unequivocal as in the cat and dog, were confused and seemed to controvert the conclusion reached from injections of the carnivora mentioned. However, according to Needham,[5] "His [William's] injections left no shadow of doubt about the matter, and the way was clearly opened up for the study of the properties of the capillary endothelial membranes separating the bloods . . ." (p. 201.)

Since, as stated above, William said that Haller[17] credited him with the "discovery" of the independence of the fetal and maternal circulations, in 1766, it seems all the stranger that this idea was not given explicit expression in the Gravid Uterus, which appeared eight years later. It also is noteworthy that Haller did not adopt William's idea in the third edition[19] of his *Primæ Linæ,* in 1767, but maintained the idea expressed by him in the edition[20] of 1751 and found even in the German edition[21] of 1788 and the English edition[22] of 1801, in which one reads as follows: "This communication of fluids between the uterus and placenta, seems to be demonstrated . . . lastly, from the passage of water, quicksilver, tallow, or wax, from the uterine arteries of the mother into the vessels of the placenta, as observed, and lately confirmed by eminent anatomists." (pp. 437-438, Section 891.) Two eminent anatomists who thought that they had proven this, according to Fasbender, were Cowper (Bidloo's Anatomy, given out by Cowper at Oxford in 1697, in his own name) and Noortwyk (Uteri humani gravidi anatomia et historia, Lugd. Bat., 1743).

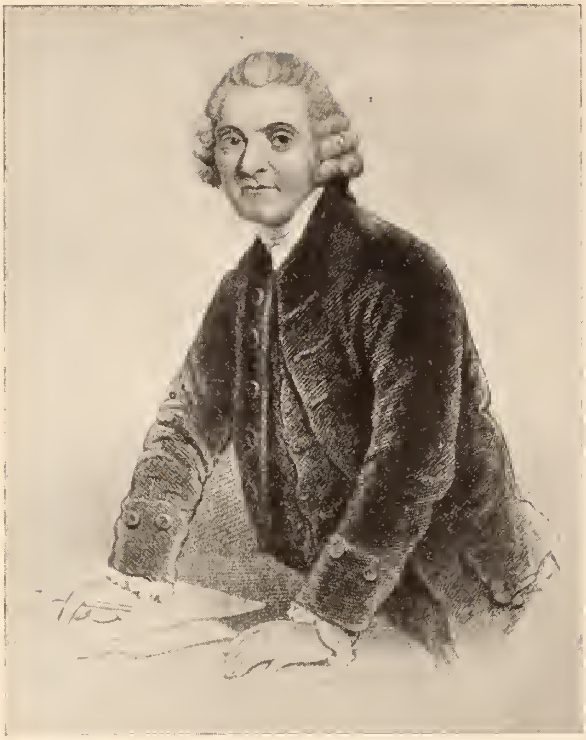

Fig. 1.—The Reynolds portrait of William Hunter, after Peachey, 1924.

The above opinion was expressed also in Volume 1 of Haller's Physiology,[23] which appeared in London in 1754, for it is there asserted that:

> This communication of the vessels, appears evident, from the loss of blood which follows from a separation of the placenta in a miscarriage; and from the blood of the foetus being exhausted from an haemorrhage in the mother; from haemorrhages that ensue from the navel-string, so as to kill the mother when the placenta has been left adhering to the uterus; and lastly, from the passage of water, quicksilver, tallow, or wax, injected from the uterine arteries of the mother into the vessels of the placenta, as is confirmed by the most faithful observations; to this add the cessation of the menstrual flux in the mother, which quantity of blood must of necessity be taken up by some other part, viz. the foetus. (p. 306, Sect. 830.)

Haller's idea of the nutrition of the fetus, and its relation to the mother, is very interesting, and is indicated by the following words from the edition[24] of the First Lines published in Edinburgh in 1786:

> There, in the common surface of the uterus and placenta, a communication is made, by which the uterus sends to the foetus, first that white serous liquor not unlike milk, and lastly, as it seems, red blood itself. This communication of the humours seems to be demonstrated by the suppression of the menses in women with child, whose blood must be turned into another channel; from the loss of blood which follows from a separation of the placenta in a miscarriage; and from the blood of the foetus being exhausted from an hemorrhagy in the mother; from hemorrhagies that ensue from the navel-string, so as to kill the mother when the placenta has been left adhering to the uterus; and, lastly, from the passage of water, quicksilver, tallow, or wax, injected from the uterine arteries of the mother into the vessels of the placenta, as is confirmed by the most faithful observations. But that it is blood which is sent into the foetus, is evinced by the magnitude of the sinuses of the uterus and placenta; the diameter of the serpentine arteries of the uterus; the hemorrhagy that follows, even when the placenta is very slightly hurt; but especially by the motion of the blood, which, in a foetus destitute of a heart, could only be given to the humours of the foetus by the blood of the mother. (pp. 211-212, Sect. 891.)

In a footnote to this passage, it is stated:

> Of the two most noted conjectures which usually explain the communication of the uterus with the placenta, resorption, or the immediate anastomosis of the blood-vessels, the last has always had the most partisans. I am sorry that various arguments, sufficiently weighty, prevent me from so easily embracing the same side; which arguments my celebrated pupils, Balthasar and Moeller, have already mentioned, and which shall now be partly delivered by myself.

Among these arguments is the following:

> By the most successful injections, made with all due care, once into the uterus of a pregnant woman who died in the seventh month of gestation of a wound, several times into the womb of mares, cows, goats, rabbits, dogs, and cats, &c. preparations of which I possess, I never could convey the smallest quantity of the most subtile liquor into the uterus from the vessels of the cord, nor from the vessels of the uterus into the placenta: the liquor entered only the cellular texture of the fungous chorion, and filled it with irregular particles.

I do not know whether John was unfamiliar with the teaching and the work of Alexander Monro primus (1696-1767), but it is rather difficult to see how William could have been, since it is stated in the Dictionary of National Biography[25] that he "spent the winter of 1740-1741 under 'Monro primus' . . . ," who, as early as 1734, according to Cole,[26] "published a striking but neglected paper in which the independence of the maternal and foetal bloods in the placenta is for the first time placed beyond question by injection experiments." (pp. 324-325.) The paper referred to by Cole is entitled " 'An Essay on the Nutrition of Foetuses,' *Medical Essays, &c.*, Edinburgh, 1734, vol. ii, 12mo.," of which Cole said some copies are dated 1733.

Sprengel[27] also had called attention to the fact that the elder Monro had determined the existence of "muscular fibers in the uterus and had rejected the idea of the direct communication of the maternal and fetal vessels." (p. 322.) He cited the Medical Memoirs of the Royal Society of Edinburgh, Vol. 2, p. 128, as his authority, but the reference in the third German edition[28] (Halle, 1828) is to the "Essays of a soc. at Edinb., vol. 3. p. 275; vol. 4. p. 450." (p. 213.) In this third

German edition Alexander Monro, Sr., and his sons, Donald and Alexander, are credited with having done much, experimentally and otherwise, to establish the correct view regarding the relations between the maternal and fetal circulations. Roederer (1725-1763) is likewise given credit for having done this and there can be no doubt regarding Monro, Sr., who wrote:[29] " . . . I cannot be more certain of anything than that there is no anastomosis or continuity of these vessels in cows." (p. 388.) He then quoted from Vieussens (Dissert. de Structura et Usu Uteri, &c., § 56):

"And again, 'The effusion of blood at birth, without doubt was also the cause why several old anatomists, who were little acquainted with the natural œconomy of the human body, yea and Mr. Mery, believed that the arteries of the womb directly opened into the veins of the placenta, and that the arteries of the placenta opened into the veins of the womb; from which they concluded, that the mother's blood circulated into the body of the foetus, and that the blood of the foetus passed into the mother's body. But the falsity of this opinion, which was refuted by many anatomists of the last century, who were not only skillful dissectors, but very learned natural philosophers, shall be most evidently demonstrated from what I am to say, when I explain the internal structure and the use of the placenta; so that the abettors of it will readily reject it.'" (pp. 390-391.)

It is true that Monro also declared that "The smaller share by far of the blood sent out by the umbilical arteries is returned to the uterus, most of it being poured into the umbilical vein by anastomosing canals. This may be seen by injecting liquors into the umbilical arteries of any creature." (p. 392.) But by this he merely allowed for the return of some of the plasma by the "absorbents" (lymphatics) which he believed existed in the placenta. Monro also believed that the maternal and fetal circulations communicated with each other by means of invisible pores too small for the passage of blood cells. This view was in entire harmony with the prevailing view regarding absorption from the intestine to which Monro, in fact, referred.

As Cole said:

> In the description of his plates of the gravid uterus, published posthumously in 1794, William Hunter states that he first injected the vessels of the foetal placenta from the navel string in 1743, but it was only when the plates were first issued in 1774 that this experiment was described. He says that he injected the placenta with wax of different colours—the uterine arteries red and the veins blue, but none of the injection mass passed into the vessels of the navel string. In the 1794 publication further details are added. The placenta of man and quadrupeds, he remarks, is composed of two parts intimately blended—a foetal element, which is the continuation of the umbilical vessels of the foetus, and a maternal, which is an "efflorescence of the internal part of the uterus" . . . When the second Monro and William Hunter were students, it was still believed that the maternal blood circulated through the foetus by the navel-string, and returned to the parental vessels, in spite of the positive demonstration to the contrary by the first Monro. Hunter's belief in injection methods was deeply strengthened by his visit to Albinus in 1748, when the beautiful preparations of the Leyden Professor fired the imagination of the Scots anatomist. (pp. 333-334.)

(To be concluded)

CONVERSATIONAL GEMS OF DR. J. P. WIDNEY*

Founder of the Los Angeles County Medical Association: At Age of Ninety-Five Still Active in Literary and Church Work

The world does not need moral soothing syrup—it needs castor oil.

You can help a man without indorsing him.

The trouble with some people is, they have more religion than piety.

It is a moral and civic mistake to try to save people from the penalty of their wrongdoing.

Live so that your life will be the only answer needed to silence slander.

Let the one who pays the bills do the planning.

When growth ceases, death has begun.

The whole cry of old and young is, "Do something to amuse us."

I am my brother's keeper, but I am not his jailer.

If you wish to look into the past, do it with a looking-glass.

Do not turn around. Lot's wife turned around.

A thing you do not need is dear at any price.

It is easier to give money than it is to give work.

There are people so clumsy they cannot turn around without stepping upon themselves.

Democracy should mean something more than dirt.

We judge the orchard by its fruit. The orchard is planted for its fruit—not to be looked at only.

Do few things, but do them thoroughly.

The history of the world may be summed up in one sentence—the struggle for life with plants, animals, and man.

There are dregs in the wine cup.

It's a great thing to die in a stylish neighborhood. It gives one a good send-off.

Tickling the palate makes Death laugh.

Hunger is nature's spur to industry.

Your stomach knows better than your brains what you should eat.

Sugar sweetens the mouth but sours the stomach.

The ultimate tenure of land ownership is occupancy and use.

The way to succeed in life is to help the other fellow

Calling a piece of paper a dollar does not make it a dollar.

The word unspoken does not have to be retracted nor explained.

The observance of the law and the safety of the home depend more upon the church than upon the policeman.

You find yourself wherever you go.

Remember, in business the small order often brings the big order.

The cart is a greater factor in man's uplift than the airplane.

A rotten egg will be worse tomorrow.

The world is perishing of gush.

You cannot make a canary out of a jackass, nor a pound cake out of a sack of cornmeal.

Post the books every night, but plan for the years.

A table blessing: We thank Thee, Lord, for daily food and for our home. Help us to do what is right and to avoid what is wrong. Amen.

Caroline, I think I'll not have time to die. (Said at 92.)

CLINICAL NOTES AND CASE REPORTS

RADIUM IN LESIONS OF THE FACE

By Irving Bancroft, M.D.
Los Angeles

At a recent meeting a prominent surgeon stated, "You cannot use radium without destroying the good as well as the diseased tissue." That opinion, seemingly widespread, is erroneous. Radium can be so filtered that diseased tissue only is destroyed, but in order to do that, the time of exposure, as well as the amount of filtration, must be correct. Destruction, in this case, is accomplished by the prevention of reproduction rather than by actual necrosis.

Unfiltered radium, it is true, destroys all tissue, and when so used as a simple destructive agent, is inferior to the actual cautery because it is not so definitely controlled. On the other hand, when it is desired to destroy only the pathologic tissue and cause no visible scar, radium must be so filtered that the rays of longer wavelength are stopped by the filter, and only those of a shorter wavelength are allowed to pass and act on the tissues.

The heavier the filtration the more nearly the efferent rays are of the same wavelength. As a result of this homogeneity, the time of application becomes the important factor and, by changing the time, different groups of cells in normal skin are destroyed. The epithelial lining of the hair follicles are the most sensitive cells in the skin, and the subcutaneous connective tissue is the most resistant. Assuming the radiosensibility of the skin as 1, the average sensibility of a carcinoma is 0.90 and sarcoma is 0.70. Other abnormal cells vary in susceptibility. Graafian follicles are about five times more sensitive than the skin. In order to get the selective action of radium to its fullest extent, all alpha and beta rays must be cut off and most of the gamma rays of long wavelength. In order to do this with ten milligrams of radium distributed over an area of one square centimeter, a filtration of one millimeter of gold and one millimeter of lead will result in allowing approximately 25 per cent of the soft gamma rays and 93 per cent of the hard gamma rays to pass and be absorbed by the tissue. The soft gamma rays are those which are totally absorbed by 20 millimeters of lead, and the hard gamma rays are those which all pass through 20 millimeters of lead. Such heavily filtered radium requires a longer or shorter period of application according to the amount of radium used. Some 240 milligram hours of

Fig. 7.—Epithelioma of five years' duration. Fifty milligrams of radium was applied in two different places for periods of eighteen hours each. Total area of the radium was about six square centimeters. Filtered with one millimeter of silver and one millimeter of lead and four millimeters of wax.

Fig. 8.—Same as Fig. 7, but taken thirty-six days later. Shows destruction of pathologic tissue only.

radium filtered as above can be used without permanent destruction of normal cells, and basal cell carcinomas will be destroyed by that dose.

The minimum requirement to filter out the alpha and beta rays is 10 millimeters of aluminum, 2 millimeters of lead, .7 millimeters of gold, or .6 millimeters of platinum. Paraffin, rubber, and other organic filters, have very little effect in stopping any of the rays; 20 millimeters of these substances allow from 91.2 to 97.8 percent of the hard gamma rays to pass. The above statements are worked out from the tables of Albert Laborde, and are based on the coefficient of absorption of the various substances.

The submitted photographs of pathologic conditions of the face are selected from many similar good results, all treated by the principles as stated above.

PUERPERAL PEMPHIGUS*

By Saul S. Robinson, M.D.
Los Angeles

ACUTE pemphigus occurring in the puerperium is rare. The cutaneous manifestations of puerperal septicemia are usually purpura, petechiae, and scarlatiniform erythema. The rarest cutaneous findings are bullae, papules, and urticarial lesions. Little reference, however, to acute pemphigus occurring during the puerperium is to be found in the literature.

REPORT OF CASE

Mrs. E. C., aet. 31, was admitted with the diagnosis of pregnancy, full term; pyelitis. The patient had complained of bladder distress one month before her admission. The urine at that time contained 2 plus albumin, and 20 to 30 leukocytes per high dry field. A diagnosis of pyelitis was made.

On August 6 the patient was delivered of a living male child. A perineorrhaphy was performed at the time of delivery.

On August 8 the temperature rose to 100.9 degrees Fahrenheit, and a large bleb, 2 centimeters in diameter, appeared on the inner surface of the left thigh. Small blebs appeared in large numbers, chiefly over the buttocks. Pus appeared at the lower angle of the episiotomy wound.

On August 12 the temperature was 104 degrees Fahrenheit, and a new crop of bullae appeared. Culture from a cutaneous bleb showed a growth of Staphylococcus aureus.

An August 13 bullae appeared on the ears and on the anterior chest. The patient's face was cyanotic and she became comatose. The temperature elevated from 105 to 107 degrees Fahrenheit, and was followed by a severe chill. Examination of the blood showed: hemoglobin, 63 per cent (Sahli); erythrocytes, 3,160,000; leukocytes, 19,600; polymorphonuclears, 92 per cent; lymphocytes, 7 per cent; basophiles, 1 per cent; coagulation time, seven minutes.

On August 14 the temperature was 105 degrees Fahrenheit, and the patient again had a severe chill. The outer layers of the epidermis became loose and detached. A diffuse vesiculo-bullous eruption covered most of the trunk and the extremities. Large areas of denuded skin with a raw, erythematous surface were present. The bullae and vesicles were thin-walled, and could be easily broken. A positive Nickolsky sign was elicited.

On August 15 more than one-half of the body surface was denuded of epidermis. The face was red, dry, and scaly. Examination of the blood showed: hemoglobin, 45 per cent; erythrocytes, 2,630,000; leukocytes, 27,250; polymorphonuclears, 94 per cent; lymphocytes, 2 per cent; myelocytes, 4 per cent.

On August 20 the patient's coma deepened. The temperature elevated from 105 to 108 degrees Fahrenheit before death. The cultures of the fluid from the bullae again grew Staphylococcus aureus.

Necropsy Findings.—The superficial skin was almost entirely removed, and a few bullae were present. There were large denuded cutaneous areas. Examination of the lungs showed adhesions at the apices and hypostatic congestion in each lower lobe. An embolus was found in a vessel of the lower right lobe. Examination of the heart revealed a vegetative growth on the anterior flap of the mitral valve. The growth was in the flap and measured five-tenths centimeter in diameter. The spleen was enlarged, dark colored, and soft. The kidneys were soft, edematous, and swollen. Each kidney pelvis was slightly enlarged and congested. Stripping the kidney capsule showed minute abscesses scattered over the kidney surface. The ureters were slightly enlarged and thickened.

The urinary bladder mucosa was edematous, congested, and had hemorrhagic areas at the trigone. The liver was enlarged, and small grayish discolorations could be noted through its capsule. Section through these discolorations showed abscesses near the surface. The liver lobulations were swollen and considerably obscured. The gall-bladder, adrenals, pancreas, stomach, and intestines were normal.

The uterus was small, involuted, and contained thrombosed vessels. A small amount of grayish exudate was on its mucus surface.

Anatomic Diagnosis.—The anatomic diagnosis was septicemia; pyelitis; cystitis; suppurative hepatitis; suppurative nephritis; chronic fibrous adhesions, apices of lungs; embolus, right lung, lower lobe; acute endocarditis, mitral; pemphigus.

The spleen cultures grew Staphylococcus aureus; a smear from the uterus showed many Gram-positive diplococci resembling staphylococci; a few streptococci were present.

The microscopic sections corresponded with the gross pathologic findings. The endocarditis seemed to be an acute exacerbation of an old fibrous condition. The liver presented a typical nutmeg appearance outside of the suppurative areas. The pathologist expressed the opinion that the patient had had an acute infection in the past which had lain dormant until the present crisis produced an acute exacerbation.

COMMENT

Brocq[1] has classified acute pemphigus of the reported type under the title, "Acute Infectious Bullous Dermatitis," while Pernet and Bullock[2] described the condition as "Acute Febrile Grave Pemphigus." The septic wounds preceding acute pemphigus have been reported to be produced in some cases by dead animal material or by animal bites. Butchers and handlers of dead animals usually suffer from this type of acute pemphigus. Vaccination wounds[3] have also been reported to precede acute pemphigus. Little reference is to be found, however, to acute pemphigus occurring in the puerperium. The infected perineal wound or, more probably, an infection in the involved internal organs may have been the source of the infection in my patient. Staphylococcus aureus was cultured from both the cutaneous lesions and the internal organs.

BEDSIDE MEDICINE FOR BEDSIDE DOCTORS

An Open Forum for brief discussions of the workaday problems of the bedside doctor. Suggestions of subjects for discussions invited.

URINARY RETENTION

I. ETIOLOGY AND PATHOLOGY

Thomas E. Gibson, M.D. (450 Sutter Street, San Francisco).—The term "urinary retention" is defined as partial or complete inability to empty the bladder. Urinary retention must be differentiated from "urinary suppression." Suppression of urine involves partial (oliguria), or complete (anuria) failure of the kidneys to secrete urine. Here the causes are some disease or toxic condition affecting the parenchyma (Bright's disease), reflex nervous influences, obstructive conditions, or a combination of two or more of these factors, as, for example, calculous anuria in which a combination of obstructive and reflex influences may cause partial or complete suppression of urine. Suppression is a failure of secretion involving the upper urinary tract, while retention is a failure of excretion involving, as a rule, the lower urinary tract.

The etiologic factors concerned in urinary retention are classified as follows:

OBSTRUCTIVE

I. *Neoplasms:*
  1. Prostatic hyperplasia.
  2. Median bar (glandular type).
  3. Cancer of prostate.
  4. Other tumors of the prostate (rare).
  5. Extravesical tumors (fibroid of uterus).

II. *Calculus:*
  1. Vesical (ball-valve action).
  2. Prostatic (encroaching on urethra).
  3. Urethral (secondary to prostatic or vesical calculus).

III. *Infections:*
  1. Acute prostatitis with swelling.
     a. Gonorrheal.
     b. Nonspecific.
  2. Abscess of prostate.
     a. Gonorrheal.
     b. Tuberculous.
     c. Nonspecific.
  3. Urethral stricture.

IV. *Trauma:*
  1. Fractures of pelvis.
  2. Straddle injuries (falling astride some object).
  3. Blow on perineum.

V. *Congenital anomalies and acquired deformities:*
  1. Congenital valves of posterior urethra.
  2. Congenital hypertrophy of verumontanum.
  3. Congenital stricture, atresia or stenosis of urethra.
  4. Diverticulum of bladder.
  5. Cystocele.
  6. Hypertrophy of trigone or interureteric ridge.

VI. *Gross hemorrhage:*
  1. Secondary to tumors of kidney or bladder.
  2. Secondary to tuberculosis of kidney or bladder.

VII. *Foreign bodies inserted in urethra:*

NEUROGENIC

A. *Central nervous system (cerebral and spinal):*
  1. Neoplasms:
     a. Primary.
     b. Metastatic.
     c. Extradural.
  2. Infections:
     a. Cerebrospinal lues.
     b. Locomotor ataxia.
     c. Luetic meningitis.
     d. General paresis.
     e. Poliomyelitis.
     f. Acute (transverse) myelitis.
  3. Toxic and degenerative lesions:
     a. Pernicious anemia.
     b. Diabetes.
     c. Multiple sclerosis.
     d. Syringomyelia.
     e. Compression myelitis (caries, tumor, etc.)
     f. Arteriosclerosis.
     g. Apoplexy.
  4. Congenital anomalies:
     a. Spina bifida.
     b. Lumbar and sacral deformities.
     c. Meningocele.
  5. Trauma:
     a. Fractures and dislocations.
     b. Gunshot and other wounds.
     c. Hemorrhage into brain or spinal cord.

B. *Peripheral nerve lesions:*
     a. Postpartum retention.
     b. Postoperative retention.
     c. Sympatheticotonia.
     d. Infectious fevers.

It is evident, from this sketchy outline, that the causes of urinary retention are multitudinous, and that, therefore, the greatest care and skill are required in their diagnosis and treatment. Prostatic hypertrophy is the most frequent obstructive cause of urinary retention, while syphilis is the basis of the majority of cases of neurogenic urinary retention. The clinical picture is frequently complicated by the fact that retention of urine is not always due to a single factor. Two or more obstructive factors may be involved; and to make the problem more involved, there may coexist a combination of obstructive and neurogenic factors which demand special consideration. For example, inflammatory swelling of the prostate may coexist with actual hypertrophy. In order to properly evaluate the degree and character of the hypertrophy, the inflammatory factor must first be controlled by proper treatment. In this connection, it must be remembered that inflammatory swelling of the prostate may cause complete retention of urine in the absence of any prostatic hypertrophy.

A very common association of obstructive factors is median bar and vesical diverticulum. In these cases the problem as to whether excision of the bar alone, or both bar and diverticulum should be done, calls for decision. A vexing problem which must be met rather frequently is the association of obstructing prostate gland and neurogenic bladder, where a clear-cut indication for prostatectomy is frustrated by the possibility of resultant incontinence. Partial or complete retention of urine is a characteristic of neurogenic bladder in the total absence of a mechanical obstructive factor. Many patients have had the misfortune of being operated on under the mistaken impression that the cause was a bladder-neck obstruction. Three cases of this nature have come to my attention. One was a woman with complete retention in a cord bladder on a luetic basis. Her suprapubic scar was a mute testimonial to an unnecessary operation. Another case was reported (1936) of vesical paralysis associated with cardiospasm, apparently due to a disturbance of sympathetic innervation. Another case under treatment is a boy without evidence of local obstruction or central nervous system disease, yet he has an enormous bladder capacity and large residual. This condition is analogous to megacolon or Hirschsprung's disease, and might be termed sympatheticotonia.

The evening of man's life is often harassed by the specter of urinary retention on the basis of prostatic obstruction. It has been stated that every other man over forty years of age suffers some degree of enlargement of the prostate. Teem (1935) has shown, in a large series of autopsies, that the prostate increases progressively in size from birth to old age. This growth reaches pathologic proportion in perhaps a third of all men over fifty years of age. The frequency with which cancer is the cause of bladder-neck obstruction, either alone or in association with benign hypertrophy of the prostate (15 to 20 per cent of prostatic enlargements are malignant), should impress every man over fifty years of age with the importance of having his prostate palpated once yearly, particularly in view of the fact that prostatic cancer is usually incurable after the appearance of symptoms. The etiology of prostatic hypertrophy has long been of great interest, and of late has received renewed attention, particularly from the endocrine viewpoint. Lower and his associates (1935), on the basis of parabiotic experiments, have constructed a hypothetical mechanism for the control of the prostate, which appears to explain the etiology of prostatic hypertrophy. Inhibin, which probably is elaborated in the tubular cells of the testicle, is diminished in amount as the age of the individual advances, and the spermatogenetic function declines. With the restraint removed, the pituitary becomes hyperactive and stimulates the interstitial cells to elaborate an excess of androtin which, in turn, acts upon the prostate to produce enlargement. In a preliminary report they are encouraged by the results obtained in treating prostatic hypertrophy with the hormone inhibin. Teem finds no histologic evidence which would point to a relation between the interstitial cells and prostatic hypertrophy. Deming and his associates (1935) state that 50 per cent of prostatic hypertrophies in man arise from the periurethral glands of the posterior urethra, which are not subject to endocrine influences, and that there is no pathologic or histologic evidence that the action produced by castration, or any hormone, influences the growth of prostatic hypertrophy. Hirsch (1936) has revived the theory of Ciechanowski, who was the first pathologist to show by pathologic section that many phases of prostatic enlargement exemplified an inflammatory reaction. Hirsch holds that benign pathologic enlargements of the prostate are due to hyperplasia, rather than hypertrophy or neoplasia, and may be satisfactorily explained upon a chronic inflammatory basis.

All the etiologic factors of urinary retention share in common the pathologic sequelae of renal damage as a result of urinary stasis with back pressure and a secondary infection. Consequently, in urinary retention the condition of the kidneys must be carefully taken into account and every effort made to correct the cause before irreparable damage to the kidneys has occurred. The highly developed diagnostic and therapeutic armamentarium, which the modern urologist has at his command, has made this goal attainable to a gratifying degree.

* * *

II. SYMPTOMS AND DIAGNOSIS

Harry W. Martin, M. D. (6253 Hollywood Boulevard, Los Angeles).—The symptoms of urinary retention depend, to a great degree, upon the cause and length of time the retention has been present, also whether complete or partial.

In the early stages of prostatic hypertrophy, the bladder may become smaller than normal, which in turn causes frequency of urination or delay in starting of the stream. A small middle lobe may be pulled down by the contraction of the trigone, allowing the bladder to empty completely, and frequently the extra work put on the trigone may cause it to tire and relax before the urinary act is complete, causing micturition in two or more stages.

Usually the bladder becomes unable to empty completely and residual urine remains after the patient has completed urination. This residuum gradually increases in most cases, which reduces the working capacity of the bladder and increases the urinary frequency.

Difficulty of urination increases gradually, accompanied with more hesitation, more straining, a smaller stream, greater frequency, and sometimes there may be blood present and pain. In other cases there may be complete retention and the patient finds that he is unable to urinate at all. The patient may also notice nausea, or even vomiting, headache, loss of appetite, dizziness, drowsiness and impairment of vision, together with a foul breath and lassitude. These symptoms may be due to chronic uremia.

Not infrequently the distress of the patient becomes very great, urination being very painful, difficult, and frequent. The patient's rest may be disturbed and, especially in cases with large residuals, the renal back pressure changes may present a very grave problem. When infection occurs, the dangers are aggravated: hemorrhage may be a very prominent symptom. In the aged, cerebral symptoms produced by arteriosclerosis are not infrequent. Pain and irritation vary greatly.

Diagnosis. — The bladder should be carefully palpated and percussed to determine its size. Cystoscopy should be delayed until bladder pressure has been reduced to normal and an examination of the blood should be made for blood urea, nonprotein nitrogen and creatinin. A phthalein test should also be made. The amount of residual urine should be noted and checked at least twice. A cystoscopic examination should be made after the above tests, including an x-ray of the kidneys, ureter, and bladder, have been made. The prostate should be examined by the finger in the rectum.

Polyuria, which may cause marked frequency, must be excluded, as must congestion of the trigone, edema, polyps, and cysts.

Infections of the urethra, prostate, and bladder may produce difficulty of urination. Contractures and bars at the vesical orifice may produce the same symptoms as prostatic hypertrophy and can only be diagnosed by careful study. Tuberculosis of the prostate must also be considered, as well as calculi of bladder, urethra, and prostate.

Diverticula of the bladder may cause retention by encroaching on the bladder, or elevating the floor of the bladder and trigone. They may be demonstrated by a simple cystogram. Bladder paralysis due to spinal-cord disease is often the source of diagnostic errors, and a careful study should be made in order to rule it out.

* * *

III. TREATMENT

W. W. Cross, M. D. (1624 Franklin Street, Oakland).—The treatment of retention will depend upon the cause and may be discussed:

First: In patients with a normal urinary tract, the condition is psychic; they are unable to void in the presence of others, the bladder becomes overdistended, the urethra stretched, voiding impossible. A soft rubber catheter relieves the retention, and avoiding overdistention prevents recurrence.

Second: Patients with disease of the spinal cord may have retention, and a soft rubber catheter will give relief. Their management is not to be discussed here.

Third: Simple, uncomplicated stricture; cleansing the external genitals with warm water and soap. The use of a local anesthetic enables one usually to pass an olive-point woven catheter of small caliber. Roughness is never required; prevents success and adds complications. Give fifteen minutes' time for the anesthetic to take effect. Dilatation later should follow.

Fourth: A simple stricture, in which attempts have been made to pass instruments, hemorrhage has been produced, the urethra wounded. The Le Fort's metal catheter or Phillip's olive point can usually be passed after the above procedure.

Fifth: Stricture complicated by abscess. Drainage of the abscess under anesthesia should first be made, and the stricture dilated. A retention catheter left to drain the bladder will usually stop urinary infiltration. When extensive urinary infiltration has developed, free drainage must be established, but the management of this serious condition cannot be discussed under retention, as the condition is one of a grave surgical interest.

Sixth: Old strictures, with urinary fistula and extensive connective tissue formation in the perineum and around the urethra. When the fistula becomes closed, acute retention results. Alcohol is frequently added as a complication. Placing the patient in a hot bath will frequently relax enough that the patient will void, and the canal can be opened; failing in this, operation will be required. Internal urethrectomy has never been one of my sins, and it has appeared to me that patients who have come under my observation have had a complication added rather than a benefit, after submitting to this procedure. Failing to pass an instrument through the urethra as a guide in my own experience, a retrograde operation is the one of choice. When sounds are passed both from above through the bladder and up to the stricture from below, one easily maintains relations, the stricture is easily divided and the canal reëstablished. An indwelling catheter retained for two or three weeks makes it possible to preserve a good canal. When a guide can be passed, the perineal incision is all that will be required. Lest my position be misunderstood, let me say that in the past ten years in my experience of dealing with stricture, operations has been resorted to but upon four occasions. Operation is rarely required and has been resorted to only in the last group, all of the patients having been operated upon before.

During the past ten years my experience with stricture has been large and has afforded an opportunity to observe the results of treatment by others. It is noticeable that operation is rarely required and should be restricted to the type indicated, as better results are obtained when it is avoided.

Seventh: Contracture at the bladder neck. As a rule there is very little difficulty in relieving the discomfort by catheter, and permanent relief is afforded by punch or the resectoscope.

Eighth: Cancer involving the prostate when retention has developed can be relieved by the resectoscope unless the tumor is large, when a suprapubic drain may be required. The management of such patients frequently is a problem. My effort has been to follow a course that guides a patient through a fatal illness with the least discomfort possible. The case under consideration must be the guide.

Ninth: Retention due to adenoma of the prostate usually can be relieved by catheter; this is not always accomplished with ease, but generally, if the soft rubber catheter cannot be passed, one of the single or double Caude catheters can. If a clot obstructs the catheter, forcing a boric solution through will dislodge the clot and the bladder relieved. Failing in effort at catheterization, a suprapubic drain may be required. Many patients so afflicted should not have the back pressure relieved suddenly; the bladder should be gradually decompressed. Whether an indwelling catheter should be installed depends on the toleration to the catheter. Many are comfortable with its use; others tolerate intermittent catheterization, which my own experience has made me prefer. This condition brings one to a consideration of bringing the patient to a stage when removal of the tumor or resection are to be considered. Whether this can be accomplished by the use of the catheter will depend upon the condition of the patient and his response to the efforts made to develop the desired situation. When the kidney function is constant, the blood chemistry lowered, tongue clear, breath odor improved, skin action good, mental condition clear, and the patient eating well, he is in a condition for relief permanently by one of the methods the surgeon may consider will obtain the best result.

Catch Many Food and Drug Offenders During Summer.—Dairy products, fruit, fish, and patent medicines predominate in the recent report of legal actions just issued by the Federal Food and Drug Administration.

Butter containing less than the legal requirements of butterfat represented the most prevalent violation. An aggregate of nearly 71,000 pounds was seized throughout the country. Short weight butter was encountered in only one small shipment, amounting to fifty-six pounds. There were also confiscated 2,900 pounds of butter in an advanced stage of decomposition.

Arsenic and lead residues on fruits brought seizure of the following: 206 crates of cherries, 39 crates of currants, 21 bushels of crabapples, and 614 bushels of apples. Other foods seized because of the presence of a poisonous ingredient were 523 shipping cases of canned sardines and 15,000 pounds of maple sugar contaminated with lead, and 3,300 pounds of calcium phosphate containing fluorin. The calcium phosphate was en route to a manufacturer of baking powder.

Infestation with a parasitic worm was responsible for the seizure of 2,150 pounds of whitefish and related species of fish from the Great Lakes and Canadian lakes area. Other seafood seized during July and August included 3,150 pounds of polluted crabmeat and 914 cases of partially decomposed canned salmon. Other seizures, because of filth and decomposition, involved the following: 635 gallons of dirty cream, 1,520 pounds of decomposed dried olives, 963 cases of tomato puree and 30 of catsup containing mold, 1,150 packages of a partially decomposed fruit spread, and 5,930 cans of a dog and cat food, also partially decomposed.

Frauds on the Purchaser. — Frauds on the purchaser blocked by governmental action are shown by seizure of the following commodities: 307 gallons of a salad oil represented as cottonseed oil when it was, in fact, 90 per cent soybean oil; 16 gallons of a so-called "olive oil" found to consist of cottonseed oil and other vegetable oils, and short volume; 200 cans of a salad oil on which the sole charge was volume shortage; 3,900 jars of short weight peanut butter; 980 jars of short weight preserves; 530 jars of preserves deficient in fruit; 200 cases of tomato puree containing less solid tomato material than is recognized by good commercial practice; 300 pounds of dried apples containing excess moisture; 212 bushels of fresh peaches represented as of grade U. S. No. 1, although below that grade; 8,450 pounds of a "milk" chocolate coating deficient in milk; 2,320 containers or chocolate-flavored "malted milk" deficient in malted milk and some of which carried unsubstantiable remedial claims; 320 packages of so-called "fruit crystals," consisting of sugar, tartaric acid, artificial color and citrus oils, packed in containers shaped like citrus fruits; 976 gallons of "orange juice, sweetened," which was really a mixture of orange juice, pulp, ground peel, sugar, artificial color, and acid; and 4,200 packages of so-called "egg noodles" artificially colored and containing no egg.

Drug Seizures. — Drugs seized during the last two months included one shipment of Bacillus acidophilus blocks found to be lacking in live bacilli, one shipment of substandard sodium fluorid tablets, 1,018 boxes of bandages represented as "sterile" but found to be unsterile, and the following patent medicines:

"Arcady Wor-A-Ton," consisting of copper sulphate, copperas, kamala, chenopodium, anise, ginger, capsicum, and nux vomica, alleged to be fraudulently represented as a treatment for poultry ailments.

"H. P. Healing Balm," a perfumed lead oleate ointment, found to be not antiseptic although represented as such, and represented as harmless in spite of its lead content.

"Hem-Roid," containing aloe, nux vomica, and witch-hazel, alleged to be misbranded because offered for the relief of hepatic congestions.

"Juice-O-Veg," a water extract of plant juices (the product was actually 95 per cent water), offered for the relief of vitamin and mineral deficiencies although practically inert in vitamins and a very poor source of minerals.

"Moxon's Liniment," consisting of 7 per cent ammonia with water, alcohol, camphor and plant drugs, offered for the treatment of rheumatism, neuralgia, spasmodic and inflammatory affections of the muscles or joints, sore feet, dandruff, sore throat, headache, lame back, general exhaustion, inflammation of the lungs, skin eruptions, inflammatory swellings, bunions, and certain ailments of livestock. (The product was also charged to be in violation of the Federal Caustic Poison Act.)

"Nervo Rumat Liniment," consisting of a red-colored mixture of turpentine, alcohol, water and camphor, for rheumatism, lumbago, poor circulation, and pleurisy.

"Silver Crown Hair-Scalp Tonic," a yellow-colored solution of quinin hydrochlorid and glycerin in water and 1.2 per cent alcohol, for dandruff, itching and scaly scalp, falling hair, and eczema.

"Tam," labeled "no drugs" and represented as a "jam" composed of "natural laxative fruits," but in fact containing senna leaves and other plant laxatives with fruit tissues. The product was also moldy.

Criminal Prosecutions.—Criminal prosecutions brought under the authority of the Federal Food and Drugs Act against shippers of adulterated and misbranded foods and drugs were terminated as follows:

Alaska Ice Pack Corporation, Cordova, Alaska; H .T. Domenici, Uyak Bay, Alaska; W. R. Gilbert Company, Inc., Cordova, Alaska; Herbert Heglin, trading as Halibut Bay Packing Company, Halibut Bay, Alaska; Al Jones, trading as Kustatan Packing Company, Anchorage, Alaska; and Washington Fish and Oyster Company, Port Williams, Alaska, partially decomposed canned salmon, fines, respectively, $10, $25 and costs, $25 and costs, $25, $15 and costs, and $26.

Van Camp Sea Food Company, Terminal Island, California, partially decomposed canned tuna, fine $300.

Red Wing Company, Inc., Fredonia, New York, tomato catsup containing mold, fine $100.

Robert J. Meguiar, trading as Mid-West Food Packers, Fowlerton, Indiana, short weight mustard containing bran, and moldy catsup containing added gum, fines totaling $400.

Benjamin Bass trading as the Corner Drug Store, Miss Hilda Frank trading as O'Donnell's Drug Store, Mrs. Catherine A. Hall trading as Hall's Pharmacy, Max Koscow trading as District Drug Stores, Enoch A. Norris trading as Northeast Pharmacy, George R. Salb, Abe Schnider trading as Capital Towers Pharmacy, William T. Kerfoot, Jr., and Louis Wolf trading as Argyle Pharmacy, all of Washington, D. C., incorrectly filled prescriptions, fine of $25 against each defendant, all fines suspended.

United Drug Company, San Francisco, California, substandard elixir iron, quinin and strychnin, fine $75.

Clark Remedies Company, Kokomo, Indiana, "E. O. Clark's Famous Liquid Formula No. 6," consisting of kamala, mineral oil, carbon tetrachlorid, turpentine, sassafras oil and water, represented as a treatment for roundworms, tapeworms, pinworms and other worms in poultry, hogs, dogs, rabbits, and cats, fine $25. . . .

CALIFORNIA MEDICAL ASSOCIATION

This department contains official notices, reports of county society proceedings and other information having to do with the State Association and its component county societies. The copy for the department is submitted by the State Association Secretary, to whom communications for this department should be sent. Rosters of State Association officers and committees and of component county societies and affiliated organizations, are printed in the front advertising section on pages 2, 4 and 6.

ASSOCIATION ACTIVITIES

COUNCIL MINUTES†

Minutes of the Two Hundred and Forty-Eighth Meeting of the Council of the California Medical Association

1. Pursuant to the call of the Chairman, the Council of the California Medical Association convened in special session in San Francisco on November 7, 1936, for the purpose of considering the report of its Special Committee on Hospital Insurance and for the transaction of such other business as the Chairman presented for consideration.

2. The meeting was called to order by the Chairman. The following officers and councilors were recorded present: President-Elect Morrow, Speaker William W. Roblee, Chairman Morton R. Gibbons, Chairman of Public Relations Committee Charles A. Dukes, Councilors K. L. Schaupp, Calvert L. Emmons, Carl R. Howson, H. J. Ullmann, A. E. Anderson, A. L. Phillips, C. E. Schoff, Harry H. Wilson, William H. Kiger, J. B. Harris, T. Henshaw Kelly, Editor George H. Kress, Secretary F. C. Warnshuis, General Counsel Hartley F. Peart, and his associate, Howard Hazzard.

Absent: President Pallette, confined to hotel room in San Francisco on account of illness; Councilors O. D. Hamlin and Henry Rogers on account of illness.

3. **Corporate Practice.**—A letter from Percy T. Magan was presented and discussed by the Council.

It was moved by Councilor Kelly, seconded by Councilor Wilson, that since the statement on corporate practice was approved by the Council, having been prepared by the legal counsel of the Association at the direction of the House of Delegates, and is a statement of the law in relation to medical practice in California and an interpretation of the legal and ethical aspects of medical practice, and since it is not aimed at any particular organization, and as no action can be taken against any organization until full knowledge of the operation and management of the organization is had, this report be published in CALIFORNIA AND WESTERN MEDICINE at the earliest possible date. Carried.

4. **Scientific Committee Report.**—Secretary Warnshuis stated that the Committee on Scientific Work had selected as guest speakers, subject to Council approval, Doctors Frank L. Meleney of New York, J. G. M. Bullowa of New York, Fred Adair of Chicago; that Dr. Herbert C. Moffitt of San Francisco would conduct a clinico-pathological conference at the second general session; and that President Pallette had the privilege of inviting one guest speaker in addition to the above speakers.

It was moved by Councilor Emmons, seconded by Speaker Roblee, that the report of the Committee on Scientific Work be approved. Carried.

A letter from the Chairman of the Section on Eye, Ear, Nose, and Throat, asking that they be granted a guest speaker, was presented, and on motion of Chairman of Public Relations Committee Dukes, seconded by President-Elect Morrow, and carried; the request was not granted, such recommendation for guest speakers being limited to the Committee on Scientific Work.

5. **Committee of Five.**—Correspondence regarding the report of the Committee of Five on the medical survey was presented to the Council. Doctors Rodney Yoell, Harry Wilson, members of the Committee of Five; and councilors discussed the functions and powers of the Committee.

It was moved by Councilor Wilson, seconded by Councilor Ullmann, that the legal counsel of the California Medical Association be made available to the Committee of Five and that the Committee of Five be authorized to take such action in conjunction with and under the instructions of the Council or the Executive Committee as will protect the Association's position in the matter. Carried.

6. **Hospital and/or Medical Insurance.**—T. Henshaw Kelly, Chairman of the Special Committee on Hospital and/or Medical Insurance, submitted a verbal report supplementing the written report of the Committee.

He stated that, after discussion with Dr. W. E. Mitchell of Alameda County, who had been asked to sit with the Committee in the absence of Doctor Dukes, Doctor Mitchell had obtained the consent of the directors of the Insurance Association of Approved Hospitals of Alameda County to operate in San Francisco County upon invitation by the San Francisco County Medical Society. Doctor Mitchell further stated that it seemed logical for the Alameda County hospitalization plan to serve as the nucleus for such activities in the Bay region.

Doctor Kelly further stated, upon information from Councilor Schoff, that Intercoast did not want to come into San Francisco or Los Angeles because of the totally different cost problem involved. He then discussed the possibility of coöperation between the Los Angeles County Medical Association and the hospitals of Los Angeles County under the leadership of Mr. Heerman, to the end that a plan might be speedily put into operation in Los Angeles and the surrounding territory.

Doctor Dukes then stated that he thought Alameda County would give consideration to any county that might ask for inclusion in the Alameda organization.

---

*All articles listed under this caption, "This Month's Topics," have been written and sent to the Editor by the Association Secretary, Dr. Frederick C. Warnshuis.

† The minutes of the two hundred and forty-seventh meeting of the Council of the California Medical Association were printed in the November, 1936, issue of CALIFORNIA AND WESTERN MEDICINE, page 430.

Doctor Ullmann stated that San Luis Obispo, Ventura, and Santa Barbara counties were anxious to be included in the territories served by the Alameda plan.

After full discussion of the advisability of operating plans at the earliest possible date, it was moved by Councilor Kiger, seconded by Ullmann, that the Council authorize the General Counsel to assist the Los Angeles County Medical Association and the Los Angeles hospitals to formulate a hospital plan in Los Angeles County. Carried.

Doctor Morrow explained the extension of curative medicine by the Federal Government into health departments which had formerly limited their field to preventive medicine. It was felt that the county societies and the health departments should work out a plan so that if the Federal Government decided to extend the Social Security Act to transient camps, indigents, etc., the problem could be handled through the health department and the county societies.

It was felt that, in accordance with President Roosevelt's assertion that individual communities should carry the burden of care for their own people, the California Medical Association should let it be known that we are ready to care for the poor in California.

It was moved by Councilor Wilson, seconded by Chairman of Public Relations Committee Dukes, that this discussion is the consensus of opinion of the Council, and it suggests that its committee work along these lines. Carried.

7. **American Medical Association Appeals.**—Doctor Dukes, representative of the Council at the appeals before the Judicial Council of the American Medical Association of Doctor Smith, et al., and Doctor Callison, et al., presented a report on the hearings and stated that the decisions had not yet been rendered.

8. **Recess.**—At this point a recess was called for luncheon.

9. **Call to Order.**—The Council was called to order after the noon recess by the Chairman, Morton R. Gibbons.

10. **County Hospitals.** — Resolution of the Riverside County Medical Society regarding the care of part-pay patients in county hospitals, was presented and discussed. Doctor Roblee stated that a ruling was desired that could be used as a guide by county societies throughout the State.

It was moved by Speaker Roblee, seconded by President-Elect Morrow, that the matter be referred to a committee of three for study and recommendations to the Council at its next meeting. Carried.

11. **Hall of Medical Science.**—Secretary Warnshuis stated that the final report of the Committee on the San Diego Fair showed outstanding bills of approximately $600 which included a bill for $300 for a film prepared by Doctor Foord, which had never been used, the preparation of which was authorized by Doctor Toland.

It was moved by President-Elect Morrow, seconded by Editor Kress, that the matter of film cost be referred to the Auditing Committee. Carried.

12. **Hospital and/or Medical Insurance.** — Further discussion was had of hospital and medical service plans.

It was moved by Councilor Kelly, seconded by Councilor Anderson, that the Council, by resolution, urges the coöperation of the Bay counties medical societies with the Alameda County Society in the development of a plan in the Bay region and urges the coöperation of the Los Angeles County Medical Association with the hospitals of Los Angeles County, to the end that they will establish a hospital plan there; and also urges the coöperation of all other counties in one of the plans approved by the California Medical Association, and that members of the California Medical Association individually and collectively give the matter their earnest assistance and coöperation; and further that the Committee on Hospital and/or Medical Service be instructed to proceed as rapidly as possible along these lines and formulate legislation on the basis of a public corporation or otherwise. Carried.

13. **Legal Department.**—It was moved by Councilor Ullmann, seconded by Editor Kress, that the proposed disbursement for printing expenses be referred to the Auditing Committee. Carried.

14. **Papers Presented at Annual Session.**—After discussion, it was moved by Editor Kress, seconded by President-Elect Morrow, that pursuant to the by-laws of the Association and the rules governing the presentation of papers at annual sessions, the Council, owing to conditions obtaining in the special instance cited, cannot make an exception and grant permission for publication elsewhere of the paper presented by the member in question. Carried.

15. **Leaflet on Publication of Papers.**—It was moved by President-Elect Morrow, seconded by Councilor Emmons, that the Editor and the Secretary be authorized to revise and arrange for publication of the leaflet, "Suggestions to Authors." Carried.

16. **Adjournment.**—There being no further business the meeting adjourned.

MORTON R. GIBBONS, *Chairman.*
F. C. WARNSHUIS, *Secretary.*

THE SEASON'S GREETINGS

"The holiest of all holidays are those
Kept by ourselves in silence and apart;
The secret anniversaries of the heart,
When the full river of feelings overflows;
The happy days unclouded to their close;
The sudden joys that out of darkness start
As flames from ashes; swift desires that dart
Like swallows singing down each wind that blows!"
"Holidays"—Longfellow.

* * *

"We ring the bells and we raise the strain,
We hang the garlands everywhere
And bid the tapers twinkle fair,
And feast and frolic—and then we go
Back to the same old lives again."
—Susan Collidge.

* * *

A few weeks and the holiday season will be at hand. To some it will be a period of sacred and meaningful days. To others a tradition, or possibly a custom, to be reënacted. To all our holiday season has its own particular meaning and is observed accordingly. May each member, during this season, experience joy and solace.

Your officers and councilors extend to members and readers a very earnest, a most sincere greeting, and wish that your holiday season be one of happiness and contentment. May the new year find you with eyes turned toward better days, with renewed inspiration and good health. To all a Merry Christmas and a Happy New Year.

* * *

HOSPITAL INSURANCE

The Council convened in special session on November 7 for the purpose of considering and acting on the report of its Special Committee on Hospital Insurance. This report may be found in the Council minutes published in this issue, together with the Council's action.

Hospital insurance is an important subject and problem. It is receiving attention and consideration by large public groups, with an increasing demand that this form of health service be made available on a voluntary basis though there are some who believe that hospital insurance should be compulsory.

The form in which it is made available is of secondary importance. The medical profession's chief concern is that it be not under political direction and that it does not fall into the hands of designing lay and political groups.

The medical profession is the only group that is competent to control and direct the providing of forms of hospital insurance by reason of its knowledge, training and experience, as well as its familiarity with the medical needs of the people.

Members are requested to send in their recommendations on this subject for the guidance of the Council.

THIS, THAT, AND THIS

(Credit given to several writers for key sentences)

"She keeps a grievance like a dog—as soon as one dies she replaces it with another." So does the member and nonmember when committees or the Association advance new procedures and action. The chronic dissenter grasps a new opportunity to exploitate a grievance or unwarranted criticism.

* * *

"Intimate as soap." A realistic statement. Many misunderstandings would be avoided were we all more intimate and frank in our relationships and dealings with those with whom we come in contact.

* * *

"Irrevocable as a hair cut." All persons have experienced occasions when the afterthought caused them to regret that they had not been more careful of their statements or deeds. There are times when amends are impossible, no matter how earnest the endeavor.

* * *

"He strains his conversation for a cigar." Let the cigar represent the dollar or personal quest. To attain the end there are those who do not hesitate to strain their integrity or utilize undue advantage.

* * *

"Elderly? Why he is so old he gets winded playing chess." Such may be the age of these observations, but it does no harm to now and then repeat certain observations.

* * *

NORTHERN CALIFORNIA TREK

On Friday, October 17, Councilor Rogers and the State Secretary set out on a 1100-mile automobile trek to visit the members in Humboldt, Del Norte, and Siskiyou counties. Up the Redwood Highway in a drizzling rain was no damper of spirits. As noon neared, the sun came out and added to the beauty of the redwood trees. At Garberville a stop was made to interview the local druggist. Here is a community of 350 voters, population of about 1,000, with a summer population of over 3,000 and many tourists. A splendid opening for a well-trained physician to whom progressive local merchants will accord cordial support.

At Eureka that evening, a well-attended meeting of Humboldt members remained in session till 11:15 o'clock. Excellent spirit exists, and questions and answers produced desirable information and understanding.

Saturday the trek extended on north to Crescent City with its well-equipped, modern hospital, where local members make available adequate medical care. Over the winding roads of the Siskiyous, paralleled with brilliant foliage, and scenery, fishermen in the streams, into Oregon, through Grants Pass, and dusk saw us at the Inn in Yreka, with its lore of gold mining days. An evening at bridge and a night of sleep in the crisp mountain climate and Sunday dawned bright and clear.

At 11 a. m., members, some driving 150 miles, arrived for the scheduled meeting. Books might be written about these medical men, their experiences in practice; how one man provides service for the people living in a radius of seventy-five miles, their abreastness to modern methods, their community activities, etc.

Then followed three hours devoted to our mutual medical interests. It was most appropriate for Doctor Bathurst to close the discussion and relate a story of his early days. Doctor Bathurst has been in practice in Siskiyou County and a member for fifty-nine years and still active and abreast of the times. It was a privilege to meet such a distinguished venerable and respected fellow member, who concluded his discussion with advice to the members: "The more I give the more do I receive from my medical society."

At 2 p. m. and home 400 miles away, via Petaluma, it was with reluctance that the invitation to dine was declined. After nine hours "behind the wheel," Councilor Rogers was delivered to his home, and the midnight ferry saw me in the home city, where bed was promptly occupied.

Would that all our metropolitan members could find the time to visit and fraternize with these fellow members in the northern counties. We are proud of them because they honor and uphold our profession.

LEGAL AND ETHICAL ASPECTS OF THE CORPORATE PRACTICE OF MEDICINE*

The House of Delegates of the California Medical Association, at its sixty-fifth annual session held May 25-27, 1936, adopted a resolution instructing the Council to formulate a letter containing an analysis of the legal and ethical aspects of corporate practice of medicine with respect to corporations so practicing and with respect to physicians rendering professional services on their behalf. The Council was also instructed to transmit its letter to all members of the California Medical Association and to those corporations which it felt might be interested in the subject. Pursuant to the resolution of the House of Delegates, we shall undertake an analysis of, first, the legal aspects of corporate practice of medicine, and, second, the ethical aspects thereof.

CORPORATIONS MAY NOT LAWFULLY PRACTICE MEDICINE OR SURGERY

1. *The Status of Corporations with Respect to the Practice of Medicine and Surgery.*—As a matter of law, it is settled beyond all possibility of controversy that, in the absence of specific *statutory* authorization, a corporation, whether or not engaged in business for profit, *may not undertake the practice of medicine or surgery,* including each of their correlated branches—such as obstetrics, gynecology, radiology, urology, pathology, pediatrics, etc. The principle just stated is the premise forming the foundation of every judicial decision bearing upon this subject, and, if the factual problems which arise from time to time were simple and clear-cut, there would be no need of any further discussion with respect to this point. However, individuals have frequently attempted to use the corporate mechanism as a means of obtaining financial remuneration from the practice of medicine or surgery, and, in doing so, have devised numerous complex and intricate schemes having as a common object the avoidance of the law's mandate. Many of the methods devised in an effort to avoid the rule that a corporation may not practice medicine have been judicially considered by the appellate courts of this State and other states. By summarizing as briefly as possible a representative group of these decisions, it is possible to convey a conception of the extent to which the courts have applied the principle of law which forbids corporate practice.

The term "corporate practice of medicine" includes the practice of medicine through agents, employees or appointees of the corporation (*Pilger* vs. *City of Paris Dry Goods Co.*, 86 Cal. App. 277; 6A Cal. Juris., p. 1260). That is to say, a corporation which employs physicians for the purpose of rendering professional services to those members of the public with whom the corporation enters into an agreement providing for medical services when necessary, is practicing medicine contrary to law. For example, in *Pacific Employers' Ins. Co.* vs. *Carpenter*, 10 Cal. App. (2nd) 592, one of the California District Courts of Appeal held that an insurance corporation proposing to furnish medical services to its policy holders through physicians appointed by it, was proposing to engage in the practice of medicine and surgery contrary to law.

It has also been held that an insurance corporation which proposed to furnish medical service to its policyholders through physicians selected by a committee of the policyholders, was proposing to engage in the practice of medicine. As a consequence, the Court refused to require the insurance commissioner to approve the form of insurance policy which the corporation proposed to issue. *Benjamin Franklin Life Assur. Co.* vs. *Mitchell*, 85 Cal. App. Dec. 1058.

Since a corporation may not employ duly licensed physicians for the purpose of furnishing their professional services to members of the general public, it is, of course, obvious that a corporation may not employ unlicensed persons to furnish professional services. *Unger* vs. *Landlords' Management Corp.*, 114 N. J. Equity 68.

The underlying reason which has caused the courts in California and through the United States to condemn any activity upon the part of a corporation which would result in the retention by the corporation (if nonprofit) or its shareholders (if in business for profit) of some of the financial rewards arising from the practice of medicine and surgery, is well expressed in the case of *Hightower* vs. *Detroit Edison Co.*, 262 Mich. 1, 86 A. L. R. 509. In that case the Court stated that it is a fundamental principle of our law that none of the learned professions, including law, medicine, and dentistry, are open to commercial exploitation, as it is contrary to the public welfare to permit a "middleman" to intervene, for the purpose of obtaining a pecuniary reward, into the personal and confidential relationship which exists between members of the learned professions and those members of the public who are their clients or patients. A physician must owe his undivided duty and allegiance to his patient; there must not be a corporation or other layman to whom the physician also owes a duty. If a physician is in effect employed by a corporation, whether it be on a salary, commission or fee basis, there is, of necessity, a divided allegiance which the law will not sanction.

---

*A bulletin issued for the information of the members of the California Medical Association, under date of October 12, 1936.

In California there is one exception to the principles which have just been discussed. In 1917 the Legislature enacted the Workmen's Compensation Insurance and Safety Act. There is a specific provision in that statute which requires that employers (which, in effect, means the insurance carrier for the respective employers) furnish the services of a physician to the employees injured in the course of employment. The statute provides that the *employer* shall select the physician; the injured employee may demand that he be allowed to choose between any one of three physicians selected by the employer. It is also specifically provided that employers shall be responsible for the compensation of the physician whose services are secured. For the limited purposes of this statute the practice of medicine and surgery by corporations is specifically authorized. In all other instances, however, the practice of medicine by a corporation is specifically forbidden by law.

In order to determine whether any particular activity upon the part of a corporation is or is not the practice of medicine or surgery, it is only necessary to apply the principle laid down in the *Hightower* case to the particular facts. If the corporation in question, or its shareholders, have been placed in such a position that it or they may secure monetary gain as the direct or indirect result of professional services rendered to members of the general public, then, as a general rule, that corporation is engaging in the corporate practice of medicine and surgery and is acting contrary to law.

2. *Physicians Who Accept Employment with a Corporation Which Is Engaging in the Corporate Practice of Medicine and Surgery Thereby Violate the Medical Practice Act and Subject Themselves to Disciplinary Action by the Board of Medical Examiners.*—Sec. 14, First (*a*) of the Medical Practice Act provides in effect that any holder of a license to practice medicine and surgery in the State of California who assists in or abets the violation of or who conspires to violate any provision or term of the Medical Practice Act, is engaged in unprofessional conduct. Consequently, it seems clear that a physician who acts as an employee or agent of a corporation which is engaged, without specific statutory authority, directly or indirectly, in the practice of medicine, is, by the very fact of his employment, guilty of unprofessional conduct. A physician who renders professional services as an employee, appointee or agent of such a corporation is, without doubt, assisting and abetting the corporation to violate that provision of the Medical Practice Act which limits the practice of medicine and surgery to regularly licensed physicians and surgeons.

A case which arose under the Dental Practice Act illustrates the present point. In *Masters* vs. *Board of Dental Examiners*, 85 Cal. App. Dec. 1086, decided June 19, 1936, the facts were: A corporation, located in San Diego, employed a dentist to render dental services to those members of the public with whom the corporation entered into contracts calling for the performance of dental services. The Dental Practice Act contains the following provisions:

"Any dentist may have his license revoked . . . for . . . aiding or abetting any unlicensed person to practice dentistry unlawfully (Dental Practice Act, Sec. 13)."

The dentist so employed was charged with unprofessional conduct in that he aided and abetted the corporation to practice dentistry. The Board of Dental Examiners found him guilty of unprofessional conduct and revoked his license. The case finally came before a District Court of Appeal, and that court upheld the action of the Board of Dental Examiners.

Returning to the Medical Practice Act, it, like the Dental Practice Act, authorizes the Board of Medical Examiners to revoke the license of any physician or surgeon found to be guilty of unprofessional conduct. Therefore, we may properly conclude that a physician who accepts employment with a corporation which is engaged in the practice of medicine or surgery contrary to law is necessarily violating Section 14 of the Medical Practice Act, and is, as a consequence of such violation, subject to disciplinary action by the Board of Medical Examiners, which may include revocation of the physician's license to practice medicine and surgery. It must be noted, however, that the conclusion just stated does not include employment by any corporation—for there are situations, such as industrial injuries, in which it is perfectly legal for a corporation to employ physicians—the conclusion only covers those situations in which the corporate employer is violating the principle of law which forbids corporate practice of medicine or surgery.

THE ETHICAL ASPECTS OF CORPORATE PRACTICE

In so far as this subject is concerned, we are, of course, interested solely in the ethical position of physicians who become employees, appointees or agents of a corporation which undertakes to practice medicine or surgery contrary to law.

The Principles of Medical Ethics of the American Medical Association are binding upon all members of the California Medical Association (By-Laws, California Medical Association, Ch. II, Sec. 1).

The Principles of Medical Ethics condemn in no uncertain terms the practices under discussion. We quote from Sec. 4, Art. VI, Ch. III:

> It is unprofessional for a physician to dispose of his professional attainments or services to any lay body, organization, group or individual by whatever name called, or however organized under terms or conditions which permit a direct profit from the fees, salary or compensation received to accrue to the lay body or individual employing him. Such a procedure is beneath the dignity of professional practice, is unfair competition with the profession at large, is harmful alike to the profession of medicine and the welfare of the people, and is against sound public policy.

A corporation is always a "lay body" in the eyes of the law, even though all of its members or shareholders are physicians. Thus, any corporation, no matter how worthy its purposes nor how noble its objects, which is illegally engaged in the practice of medicine or surgery is necessarily doing so "under terms or conditions which permit a direct profit from the fees, salary or compensation received to accrue to the *lay body*."

With respect to "direct profit," it must be remembered that, under the law, one of the tests of whether or not a corporation is engaging in professional practices contrary to law is: Are the activities of the corporation such that it or its shareholders will secure fees, commissions or other payments for professional services? It is only when the answer to this question is "Yes" that we have a violation of the rule of law forbidding corporate practice. Hence, a physician who is in the employment of such a corporation is unquestionably guilty of unprofessional conduct. Further comment on the ethical aspects of the corporate practice of medicine would seem unnecessary.

CONCLUSION

We have endeavored to analyze as briefly as possible the legal and ethical aspects of the corporate practice of medicine in accordance with our instructions from the House of Delegates. Necessarily, our analysis merely deals with the general problem.

If you, as a member of the California Medical Association, have good reason to believe from facts within your personal knowledge that any corporation is engaging in the corporate practice of medicine contrary to law, or that any physician is unlawfully aiding and abetting any corporation to so violate the law, it is suggested that you communicate such facts within your knowledge to the secretary of your county society, so that he in turn may report to this office.

Morton R. Gibbons, M. D.,
Chairman of the Council.
F. C. Warnshuis, M. D.,
Secretary.

* * *

ANNUAL CONFERENCE OF STATE SECRETARIES AND EDITORS

The well designed and spacious new auditorium in the remodeled building of the American Medical Association in Chicago was dedicated by the 1936 Conference of State Secretaries and Editors on November 16 and 17.

The following program governed the conference:

Monday, November 16—10 a. m.

Call to Order—Rock Sleyster, Chairman of the Board of Trustees of the American Medical Association.
Address—Charles Gordon Heyd, President of the American Medical Association.
The Michigan Filter System—L. Fernald Foster, Secretary of the Michigan State Medical Society.
The Public Health League of California—Glenn Myers, Los Angeles.
12:30 p. m., Luncheon.

Monday, November 16—2 p. m.

Address—J. H. J. Upham, President-Elect, American Medical Association.
The United States Public Health Service and the Social Security Act—Thomas Parran, Surgeon-General, United States Public Health Service.
The Children's Bureau and the Social Security Act—Miss Katherine F. Lenroot, Chief, Children's Bureau, United States Department of Labor.
Practical Hints on the Preparation of Manuscripts and Illustrations—Richard M. Hewitt, Rochester, Minnesota.

Monday, November 16—6:30 p. m.

Dinner Conference of Editors of State Medical Journals—Holman Taylor, Secretary-Editor, State Medical Association of Texas, presiding.

Tuesday, November 17—9:30 a. m.

Insurance Against Alleged Malpractice—Mr. Thomas V. McDavitt, Bureau of Legal Medicine and Legislation, American Medical Association.
The Scientific Exhibit at Annual Meetings of State Medical Associations—Thomas G. Hull, Director, Bureau of Exhibits, American Medical Association.

Referred for Discussion by House of Delegates

Consultation and Correspondence with Bureau of Legal Medicine and Legislation.
Violation of Laws Pertaining to Narcotics.

* * *

These conferences were initiated in 1910, and this year's conference was the twenty-third that your secretary has attended. The conference affords a valuable opportunity for state medical officials to gain intimate knowledge of conditions and movements affecting medical practice and organized medicine in the several states of our Union. Much confidential information is imparted.

* * *

The Social Security program has been credited as being the entering legislation for federal and state medicine. It was, therefore, with keen and attentive interest that the address of Surgeon-General Parran of the United States Public Health Service and the statement of Miss Katherine F. Lenroot, Chief of the Children's Bureau of the Department of Labor, were listened to. The following are some of the outstanding statements that were made by these two federal officials:

1. We are anxious to make common cause with the medical profession.
2. Our great desire is to work for the common good.
3. Prevention is of first importance.
4. Funds for states will be furnished on the basis of population, financial resources, and public health need.
5. We recognize that it would be unfortunate were we now to crystallize and form a fixed national plan. We must wait to gain experience.
6. Hence, in the beginning we are asking state health departments and agencies to formulate their own programs and budgets which will be submitted for review and approval.
7. We recognize the danger of influence and control, and are guarding against it.
8. Our efforts are nonpartisan.
9. We recognize the danger and the harm that can be done by untrained personnel.
10. We propose to strengthen and extend the work of health departments throughout the country.
11. Each state must meet its own needs.
12. We shall train the personnel.
13. We propose to investigate disease and sanitation.
14. We shall study and improve present public health methods.

* * *

Surgeon-General Parran then imparted what he termed his health philosophy:

1. The health provisions of the Social Security program are here to stay.
2. The state of the public health is a matter of national concern and interest.
3. Control of treatment is important and we must concern ourselves with the existing facilities for diagnosis and treatment.
4. I hope we will have full coöperation.
5. The mass medical problems of a community are of national concern.
6. The Public Health Service is a means, and not an end, for better health.
7. We need to concern ourselves with infant mortality, pneumonia, cancer, heart disease, tuberculosis control, and syphilis.
8. I have no plan to impose on any state.
9. We ask medical organizations to coöperate by appointing suitable committees that will advise and aid.
10. The care of the indigent is going to require study because society is going to demand better care for the indigent.
11. We must study the needs of a state and then make a local approach.
12. I do not believe that there will ever be any national scheme of health insurance or social medicine.

* * *

We are open-minded and pass these statements without comment. They do provide food for serious thought.

The Children's Bureau proposes to interest itself, under similar principles, in the enhancement of the welfare of infants and maternal care. It purposes to coöperate through state and local medical organizations and existing agencies.

Time, therefore, will relate the type, scope and extent of legislative control and provision of medical and health care.

Further comment on the other topics considered by the conference will be presented in subsequent issues.

C. M. A. DEPARTMENT OF PUBLIC RELATIONS†

Charity Service and Income Tax

From time to time suggestions have been advanced for a movement to obtain income deductions credit for charity services rendered by physicians. These suggestions have not been ignored. Careful consideration and investigations have been had.

Inasmuch as the subject has been brought up anew, the following letter is presented for our members' information.

American Medical Association
bureau of legal medicine and legislation

October 21, 1936.

Dear Doctor Warnshuis:

During Doctor Woodward's absence, I acknowledge receipt of your letter of October 13 relative to a movement to obtain federal legislation enabling physicians to deduct, in the computation of their federal income taxes, the value of the services rendered to charity patients.

The Revenue Act of 1936 provides, by Section 23, that in computing net income there shall be allowed as deductions:

---

† The complete roster of the Committee on Public Relations is printed on page 2 of the front advertising section of each issue. Dr. Charles A. Dukes of Oakland is the chairman, and Dr. F. C. Warnshuis is the secretary. Component county societies and California Medical Association members are invited to present their problems to the committee. All communications should be sent to the director of the department, Dr. F. C. Warnshuis, Room 2004, Four Fifty Sutter Street, San Francisco.

"(*o*) In the case of an individual, contributions or gifts made within the taxable year to or for the use of: . . .

"(2) a corporation, or trust, or Community Chest, fund, or foundation, organized and operated exclusively for religious, charitable, scientific, literary, or educational purposes, or for the prevention of cruelty to children or animals, no part of the net earnings of which inures to the benefit of any private shareholder or individual, and no substantial part of the activities of which is carrying on propaganda, or otherwise attempting, to influence legislation. . . ."

In 1920, the United States Commissioner of Internal Revenue, in construing a somewhat similar provision in the Revenue Act of 1918, rendered the following decision:

"Contributions or gifts made within the taxable year to corporations organized and operated exclusively for charitable purposes, which are deductible for income tax purposes from the gross income of individual taxpayers under Section 214 (a) 11, Revenue Act of 1918, have been construed to mean gifts of *money or property*. The value of services rendered to charitable institutions may not be allowed as a deduction under the aforesaid section."

So far as I am informed, the statement rendered by the Commissioner of Internal Revenue in 1920 still obtains. Charitable contributions made to *individuals* are not deductible, whether the contributions are in the form of services or in the form of donations of money or other property.

So much for the present situation. The problem of a physician's deducting, in the computation of his income taxes, the value of the services he gives to charity patients is not so simple as it may seem. In the first place, some convenient and practical way would have to be arrived at by which the value of such services could be computed in terms of dollars and cents, and in doing so the gross value of the services would have to be diminished by the money value to the physician of his hospital connection, if the services were rendered in connection with a hospital patient. In the second place, if a physician should be granted the right to deduct the hypothetical value of such services, as charitable contributions, he might equally well be expected to add to his income the hypothetical value of such services. Unless he first made this addition to his income, it would be difficult to see just how he could take credit for it as a contribution, since he cannot contribute what he does not have. In the end, I cannot see any likelihood that a physician would be any better off under the proposed scheme than he is now.

Furthermore, at the present time every effort seems to be directed toward increasing the federal revenues from taxation. Any legislation, therefore, calculated to reduce these revenues is not likely to receive favorable consideration or even to be kindly received. If the medical profession should be placed in a position of asking for itself a tax reduction at a time when every other group is threatened with increased taxation, a reaction against the medical profession might be aroused that would stimulate interest and favorable action looking toward the establishment of state medicine.

This entire matter was considered by the Board of Trustees in May, 1936, when it was decided by the Board that the time was not propitious for organized medicine to seek the enactment of this legislation.

J. W. Holloway, Jr.,
Acting Director.

* * *

"Dr." Versus "M. D."

In this day when doctor degrees are conferred by academic institutions or law to many individuals, the common noun "doctor" indicates that the possessor of that degree is only a learned man or teacher. This noun or adjective prefix does not indicate or identify the science or profession of the individual. So many persons employ this title that it is impossible to identify the doctor of medicine.

It is suggested, in fact urged, that all who hold the degree of doctor of medicine desist from using the adjective "doctor" as a prefix to their names on their stationary, signs, and when registering, and instead affix the abbreviations, "M. D." to their names.

Identify yourself at all times and in all places when signing your name by appending "M. D." to your name. A moment's reflection will cause you to perceive the purpose of this recommendation. Observe this practice from now on and identify yourself with the profession of medicine.

Medical Service Through Deferred Payments

Several states and a few of their larger county medical societies have inaugurated plans whereby patients may obtain medical services by means of deferred payments. Where these plans have been instituted and have had operating experiences, the reports impart that patients and doctors are satisfied by reason of these financial arrangements.

The Medical Society of Milwaukee County, Wisconsin, is one of the recent county units adopting this plan. The following is their explanatory statement:

How Medical Service Will Aid Your Patient

Perhaps if a hypothetical case is used as an illustration, the manner in which medical service will operate will be made clear.

Mr. X. works in a mercantile establishment. He had learned through publicity given Medical Service that medical care, which his doctor informs him he needs but for which he cannot pay in a regular manner, can be arranged for on a deferred or monthly payment basis, and, if necessary, charges can be reduced to meet his ability to pay.

Mr. X., therefore, goes to his family physician, Dr. J., who agrees that the Service can assist by estimating the total cost of the services needed on the basis Mr. X. can afford. It happens that Mr. X., in the opinion of his doctor, needs an operation for the removal of stones in the kidney. Dr. J. suggests that radiographs are necessary; also the services of a specialist, plus hospitalization.

Mr. X. arrives at the offices of the Service with a proper introduction from his doctor. Prior to an analysis of his ability to pay he is directed to the specialist recommended by Dr. J., who will estimate the cost of his work. Other costs are also ascertained. The budget consultant of the Service will then make an analysis of Mr. X.'s financial situation. Upon the facts obtained from Mr. X. and other sources at the disposal of the Service, the consultant determines that Mr. X. can pay $200 for services which at regular rates would total $300, in monthly installments over a period of ten months.

Dr. J., the family physician, Dr. B., the specialist, Dr. R., the roentgenologist, Dr. O., the pathologist, and the hospital, are informed of the patient's financial situation. With their approval an agreement is entered into between the Service and the patient. As payments are made by Mr. X. to the Service, they will be credited to his account and distributed pro rata to those who have rendered service.

There are variations from this hypothetical case in actual practice. For example: a number of patients will not require some of the laboratory procedures, and others will not require hospitalization. Fundamentally, the procedure to be followed is the same.

Keep in mind that the Service sets no fee for the doctor, hospital or any of the participants, it being understood that charges to be made are those which would ordinarily be made to persons in similar circumstances. It has been the experience of bureaus in other cities, similar to Medical Service, that the majority of patients do not need to have their bills reduced if they are given the privilege of paying in monthly installments.

If a patient has no family physician and comes directly to the Service, he will be given a list of Society members from which he may choose the physician he wishes to attend him. When this choice has beed made the physician will be called and informed of the circumstances, suggesting that the Service will be glad to coöperate with him if he so desires.

Each individual case will be judged on its own merits and arrangements made accordingly—always, however, with the approval of those giving service.

It would seem that it would be advantageous for some of our county societies to inaugurate similar plans.

COMPONENT COUNTY MEDICAL SOCIETIES

HUMBOLDT COUNTY

The Humboldt County Medical and Dental Societies met on the afternoon and evening of October 7 in joint meeting at the Humboldt Golf and Country Club, with the president, J. S. Woolford, presiding.

Fifteen dentists and nine physicians were present. Golf was played in the afternoon, followed by a chicken dinner at 6:30 o'clock.

At eight o'clock papers were read by Drs. L. P. Monson and Don Aubertine on the subject, *Pathology and Treatment of Oral Sinusitis as Taken From the Medical and*

Dental Point of View. The subject was widely discussed, especially by the dentists.

This was followed by remarks from Dr. Charles Falk, Sr., president of the local Public Health League. Doctor Falk presented Doctors Cushman and Gurley, who gave very excellent reports on new legislation which was to be presented to the public, and of vital interest to the dental and medical societies.

Lawrence A. Wing, *Secretary.*

⁂

PLACER COUNTY

The annual meeting of the Placer County Medical Society was held Saturday evening, November 7, at the Freeman Hotel, Auburn. The meeting was called to order by the president, Louis E. Jones, at 8:20 o'clock. In addition to President Jones there were present the following members and visitor:

Members—Drs. L. W. Empey, R. H. Eveleth, P. D. Barnes, Ray C. Atkinson, Vernon W. Padgett, Robert A. Peers, Daniel L. Hirsch, B. W. Hummelt, D. M. Kindopp, Mildred E. Thoren, Harold L. Karo, Max Dunievitz, C. C. Briner, W. M. Miller, J. A. Russell, and C. E. Lewis.

Visitor—Dr. John Napier of Auburn, principal of the Placer Union High School, who had been invited by the secretary to meet with the members of the Society to discuss the presence of the scarlet fever epidemic among high school and grammar school students of Auburn.

Doctor Napier explained the control measures which are being taken to protect the Student Body, and asked for full coöperation of the members of the Society. This coöperation was promised.

Following the approval of the minutes of the meeting of July 11 and of the secretary's and treasurer's reports, the application of Dr. A. S. Churchill of Weimar for membership was read for the first time.

There were a number of case reports by various members.

This being the annual meeting, election of officers was held and the following were unanimously elected: Dr. C. E. Lewis of Auburn, president; Dr. William M. Miller of Auburn, vice-president; Dr. Robert A. Peers of Colfax, secretary-treasurer.

There was no election for delegate and alternate, as Doctor Empey of Roseville and Dr. Mildred E. Thoren of Weimar, delegate and alternate, respectively, hold over for one more year.

Dr. Ray C. Atkinson and Dr. C. C. Briner presented a moving picture, showing *Technique of Suprapubic and Vaginal Hysterectomy.* A vote of thanks was tendered Doctors Atkinson and Briner.

There being no further business the meeting adjourned for refreshments.

Robert A. Peers, *Secretary.*

⁂

SACRAMENTO COUNTY

The regular meeting of the Sacramento Society for Medical Improvement was called to order by the vice-president, Dr. Ray M. Wallerius, at the Auditorium on Twenty-ninth and L streets on October 9, with sixty members and guests present.

The paper of the evening was presented by Dr. Edward F. Roberts of New York City, a member of the professional staff of the Lederle Laboratories. He spoke on *The Management of Pneumonia* and on *Pernicious Anemia,* and his discussion was illustrated with motion pictures. The papers were discussed by Doctors Gundrum, Primasing, Pulford, Railsbach, Reardan, and Scatena.

The application of Dr. Charles V. Soracco of Placerville was read for the second time and voted upon. He was unanimously elected to membership in the Society.

A card was received from the family of our late member, Dr. Hugh Beattie, expressing appreciation for the Society's floral tribute.

A letter from Dr. Etta Farmer of Folsom was read, presenting a gavel to the Society.

A letter from Doctor Warnshuis, advising approval of the Intercoast Hospitalization Insurance Association by the Council of the California Medical Association, was read.

Norris R. Jones, *Secretary.*

SANTA BARBARA COUNTY

The regular meeting of the Santa Barbara County Medical Society was held at the Santa Maria Club, Santa Maria, Monday evening, October 12, President Gray presiding.

This was a dinner meeting, under the auspices of a group of the Santa Maria members, and the refreshments and the barbecued meats were excellent. A most enjoyable time was had by all.

The speaker of the evening, Dr. John Renshaw of Los Angeles, held his audience fascinated with his interesting and instructive description of the *Gastroscope,* vividly illustrating with colored slides the differential diagnosis of the gastric disorders.

Doctor Renshaw was highly complimented by the membership for his original research work in this field, and it was felt that his availability to the profession of Southern California would be of great value in the early diagnosis of gastric malignancies.

The Santa Maria group are to be congratulated for a most successful and enjoyable meeting.

* * *

The regular meeting of the Santa Barbara County Medical Society was held Monday evening, November 9, in the Bissell Auditorium, President Gray presiding.

President Gray called upon Dr. Caleb Stone to introduce the speaker of the evening, Dr. Dorrell Dickerson of Los Angeles.

Doctor Dickerson gave an extremely interesting and comprehensive talk upon *Intracranial Tumors,* illustrated with lantern slides.

Discussion followed by Drs. Clark, Geyman, Hamilton, Van Paing, Stone, Brush, and Koefod.

Doctor Ullmann, as councilor, reported upon the present status of hospital insurance and advised that the Society take action.

Doctor Markthaler, reporting for Doctor Robinson of the Hospital Insurance Committee, said that the Board of Directors of the Alameda Hospital Insurance group advised against Santa Barbara County joining with that group at this time.

The secretary was instructed to read the action taken by the Council of the Santa Barbara County Medical Society regarding hospital insurance, and Doctor Gray reported that the two hospitals were willing to coöperate, provided they could see a complete copy of the proposed plan, and provided that the plan was endorsed by the County Society.

It was moved, seconded and carried, that the Hospital Insurance Committee be empowered to take any necessary action regarding the adoption of any hospital insurance plan, such action to be under the supervision of the Council.

The minutes of the last Council meeting were read, and then further discussed by Doctor Freidell. The Santa Maria school contract was discussed, but no action was taken, as the legality of the proceedings was referred to the state councilor for an opinion.

Doctor Hare, reporting for the Publicity Committee, said that speakers were being assigned whenever necessary.

Drs. C. W. Henderson, P. F. Munch, Lester Jankay, and Walter M. Anderson were elected to membership.

William H. Eaton, *Secretary.*

⁂

SHASTA COUNTY

The meeting of the Shasta County Medical Society was held Monday, November 9, in the office of Doctor Hansen, Redding, with President M. D. Pratt presiding.

The most important business of the meeting was the election of officers. Dr. O. J. Hansen was elected president for 1937; Dr. C. C. Gerrard, vice-president; and Dr. L. J. Seeley, secretary-treasurer.

The following resolution was passed unanimously:

Whereas, There has been presented to this Society a determination by the California Medical Association that the dues to the State Association for 1937 shall be $15 instead of $10; and

Whereas, Dues in the past have not been productive of sufficiently beneficial results to the medical profession to justify even a State annual assessment of $10; therefore be it

Resolved, That the Shasta County Medical Society hereby protests prospective increase in dues as unjustified and unwarranted.

Shasta County Medical Society.
By Leslie J. Seeley, *Secretary-Treasurer.*

Dr. M. D. Pratt was given a vote of thanks by the Society for his faithful devotion to duty as president for the past two years. It is worthy of note that Doctor Pratt did not miss a single meeting of the Society in that time and that he had to drive 150 miles in order to attend those meetings.

Leslie J. Seeley, *Secretary.*

⁂

SOLANO COUNTY

The regular meeting of the Solano County Medical Societl, held November 10 at the Casa de Vallejo Hotel, was given over to matters pertaining to the conduct of the Society, and no professional discussion was held.

The annual election of officers resulted in the election of Dr. Herman B. Perkins of Vallejo as president; Dr. Carlton Purviance of Fairfield, vice-president; and Dr. John W. Green of Vallejo, secretary-treasurer.

Doctor Green was also chosen as delegate to the 1937 session of the California Medical Association, and Dr. Arvil E. Chappell, retiring president, was chosen as alternate.

John W. Green, *Secretary.*

⁂

TULARE COUNTY

The regular meeting of the Tulare County Medical Society was held on Sunday, October 14, at Motley's Café in Visalia.

In attendance were Doctors Hill, Cronemiller, A. Bond, A. Miller, Furness, Ginsburg, P. Miller, N. Miller, Fillmore, Weiss, Glaser, Matthias, Rosson, Lipson, Preston, Watke, Kohn, Guido, Falk, Zumwalt, and McClure.

Dr. Mark A. Glaser of Los Angeles presented a paper on the *Newer Aspects of the Etiology and Surgical Treatment of Convulsions.* Many lantern slides were used to illustrate the talk, which was well received, and led to a general round-table of discussion.

Dr. A. E. Anderson of Fresno, district councilor, was present and outlined the activities of the Council, particularly with reference to the hospital insurance plan and other proposed legislation.

A vote was taken on the proposed amendment to our by-laws regarding a code of disciplinary procedure, and this was unanimously carried.

Karl F. Weiss, *Secretary.*

CHANGES IN MEMBERSHIP

New Members (42)

Alameda County.—Dean E. Hart, William J. Kennedy, Joseph L. Marriott, Charles Newell Mell.

Kern County.—Eric F. Colby, Carl Louis Moore.

Los Angeles County.—Madeline J. Algee, Montrose M. Bernstein, Fred E. Bradford, George C. Brandt, Albert F. Brown, Claude C. Bunch, P. Price Cobbs, Charles L. Cooper, Frank J. Costa, Michael M. Gurdin, George W. Hewitt, Arthur H. Hurd, Lester Jankay, Russell Johnson, Francis X. McDonald, Clarence H. Nelson, Edward S. Powers, James F. Presnell, Ethel R. Schlesinger, Lawrence W. Smith, M. J. Speigel, Beatrice M. A. Tomblin, Carrol L. Weeks, John Wilbur Whitsett.

Monterey County.—Edwin M. Chase, Howard E. Clark, Frank Hilton Smith.

Riverside County.—Howard A. Wood.

San Francisco County.—Robert D. Dunn, Russell F. Jaekle, John Edward McGuinness, Ambrose Merrill, Lester Sawyer, Lydia Shimkin, William Sullivan.

Santa Clara County.—Harold R. Carter.

Transferred (1)

Elliot Rouff, from Monterey County to Santa Clara County.

In Memoriam

Beard, John Lyman. Died at Berkeley, November 9, 1936, age 49. Graduate of the Hahnemann Medical College of the Pacific, San Francisco, 1913, and licensed in California the same year. Doctor Beard was a member of the Contra Costa County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

✠

Goodenow, Norman H. Died at Eagle Rock, October 14, 1936, age 66. Graduate of Rush Medical College of the University of Chicago, 1892. Licensed in California in 1920. Doctor Goodenow was an honorary member of the Los Angeles County Medical Association, the California Medical Association, and the American Medical Association.

THE WOMAN'S AUXILIARY TO THE CALIFORNIA MEDICAL ASSOCIATION†

County Auxiliary Letters

Alameda County

The first general meeting of the Woman's Auxiliary to the Alameda County Medical Association was held at the Claremont Country Club on September 18.

Luncheon was served to sixty-four Auxiliary members. Each table had been individually decorated with mixed flowers of the season. Mrs. Clarence Page presided.

The following recommendations were presented to the Auxiliary:

1. The Executive Board recommends to the Auxiliary the payment of $15 for membership in the Public Health League of California. The recommendation carried.

2. The Executive Board recommends that a year book be printed and that the president appoint a special committee to handle the work. The recommendation carried.

3. The Executive Board recommends that the Student Loan Fund be changed to a Scholarship Fund. After discussion a committee was appointed by Mrs. Page to investigate the matter of Scholarship and Loan Funds, and report at the next meeting.

4. The Executive Board recommends that billheads be printed for Auxiliary use in sending out notices for dues. The recommendation carried.

Mrs. J. R. Henry gave a brief colorful report of the convention held in May in Coronado.

Mrs. Baxter, as general program chairman, gave an outline of the programs to be given for the ensuing meetings.

The aims and purposes of the Auxiliary were brought before the members in a very decisive and interesting way by means of a dialogue between Mrs. Page and Mrs. Baxter.

Mr. Ben Read of the Public Health League of California spoke on *"Who's Who, What's What, and Why."* His talk dealt with the structure of the State Legislature and of the enormous number of bills which are presented at each session, many of which directly or indirectly affect the practice of medicine. He stressed three vital issues which are coming up for voting and asked the Auxiliary to help in campaigning against them. He also stated that the Auxiliary could be of great help in instructing those who are elected from our local districts as to the problems of legislation where it affects medicine.

---

† As county auxiliaries of the Woman's Auxiliary to the California Medical Association are formed, the names of their officers should be forwarded to Mrs. Robert M. Furlong, chairman of the Publicity and Publications Committee, Linden Lane, San Rafael. Brief reports of county auxiliary meetings will be welcomed by Mrs. Furlong and must be sent to her before publication takes place in this column. For lists of state and county officers, see advertising page 6. The Council of the California Medical Association has instructed the editor to allocate two pages in every issue for Woman's Auxiliary notes.

Mrs. Albert Meads, honorary member of our Auxiliary, asked for continued coöperation from the Auxiliary in helping to get out Christmas Seals for the Tuberculosis Association.

There was no further business and the meeting adjourned to meet in November.

* * *

The annual husbands' dinner given by the Auxiliary to the Alameda County Medical Association was held on Thursday, October 29, at the Claremont Country Club in Oakland.

Mrs. Clarence W. Page, the newly elected president of the Auxiliary, presided at the speakers' table. Seated with her were: Doctor Page, Dr. and Mrs. A. A. Alexander, the latter president-elect of the Auxiliary; Dr. and Mrs. W. E. Mitchel, the former president of the Alameda County Medical Association; Dr. and Mrs. Thomas Clark, the latter past president of the State Auxiliary; Dr. and Mrs. Frank Baxter, the latter first vice-president of the Auxiliary; Dr. Gertrude Moore, secretary of the Alameda County Medical Association; Dr. and Mrs. Don Weaver, the latter program chairman for the husbands' dinner, and the guest artists for the evening.

After the introductions at the speakers' table, Mrs. Page called upon Doctor Mitchel, who responded with a very splendid tribute to the wives of all doctors.

There were two hundred Alameda County doctors and their wives present at the dinner. Mrs. Maxwell Thebaut, as chairman of the decoration, had made the clubroom most attractive and festive by each table having as its centerpiece a golden pumpkin filled to overflowing with the fruits and the grains of the harvest season. Indirect colored lights and tall candles threw soft gleams over the assembly.

The entertainment for the evening was provided by three National Broadcasting Company artists. Benny Walker, editor of the Woman's Magazine of the Air, who gave clever impersonations of "Little Benny," and who was also master of ceremonies for the evening; Miss Jean Cowan, who sang several songs very delightfully, playing her own accompaniments; Armand Girard, baritone, assisted by Mrs. Girard, who thrilled the guests by his very splendid rendition of "Home on the Range," "Glory Road," and "Old Man River."

At the close of the dinner a social half-hour was spent, every one most enthusiastic over the enjoyable evening spent together.

Mrs. John Ohanneson, *Chairman of Publicity.*

⁂

Contra Costa County

The Contra Costa County Auxiliary met on Tuesday evening, November 10, at the home of Mrs. C. R. Blake for an enjoyable social evening.

Members present played contract, and prizes were won by Mrs. H. L. Carpenter and Mrs. L. A. Hedges. Refreshments were served by Mrs. Blake.

A dinner, put on by the Contra Costa County Medical Society, will be held December 12, and members of the Auxiliary will be guests. Scene of the dinner will be the Orinda Country Club.

⁂

Fresno County

The Fresno County Auxiliary was delighted last week to receive a visit from our state president, Mrs. Thornton. Mrs. Thornton was the house guest, while in Fresno, of Mrs. George Walker.

Our meeting on November 4 was in the form of a luncheon, held at the Sunnyside Country Club, with Mrs. Thornton as our guest speaker. The group was so very interested in all that she had to tell us of the aims and ideals, the founding and progress of the Auxiliary. A group of musical selections was heard throughout the luncheon.

In October the program was an unusual and an entertaining one. Mrs. C. M. Vanderburgh, Program Chairman, brought before the group a debating team quite well known throughout the valley. These boys debated the question, *Resolved, That the various states should enact suitable legislation to furnish adequate medical care.* Both sides of the question were well prepared and admirably presented. Considering the strong opinions and prejudices of the audience, the affirmative upheld his points bravely.

A benefit card party is being planned for December, with the Hygeia Committee, headed by Mrs. A. T. Goldberg, in charge. The proceeds will purchase *Hygeia* subscriptions to be placed in libraries, schools, and beauty parlors. We are hoping to have an excellent report of this party for the next issue.

Mildred Diederich, *Secretary.*

⁂

Los Angeles County

The Woman's Auxiliary to the Los Angeles County Medical Association had a delightful meeting Tuesday, October 27, at the Uplifters Ranch in Santa Monica, with 152 present, and with Mrs. Andrew J. Thornton, president of the State Auxiliary, as guest of honor. In answer to the cordial invitation sent out to eligible members, twenty-three new members were added to the roll, and many more were guests. Luncheon was served at twelve o'clock.

Mrs. Harold Crowe, chairman of the Social Welfare Committee, announced plans for the Thanksgiving baskets to be given to thirty families of doctors on relief in the county. She asked for donations of canned goods, sweets, or small packages of staples.

The president, Mrs. Wright, introduced Mrs. Thornton, who spoke briefly on the importance of individual members educating the public in an unofficial way in the interest of scientific medicine.

The chief speaker of the day was Mrs. Steele Stewart, whose interesting subject was *The Medical Set-Up in Hawaii.*

Special music was arranged by Santa Monica members.

Mrs. Robert L. Carroll, *Chairman of Publicity.*

⁂

Marin County

On Thursday evening, October 22, the Woman's Auxiliary to the Marin County Medical Society met with the Marin County Public Health League at a dinner meeting held in the Marin Golf and Country Club, San Rafael.

An attendance of approximately one hundred members and guests filled the dining room of the Club to its seating capacity. All business of the individual branches was dispensed with.

Before introducing the speakers of the evening, Dr. Scott Polland, president of the Marin County Public Health League, expressed his appreciation of the display of interest shown and congratulated the Woman's Auxiliary on its growth, commending the members not only for their own attendance, but also for an increased attendance on the part of members of the Medical Society since the Auxiliary was organized.

The main speakers of the evening were: Dr. Alson Kilgore, Doctor Johnson, treasurer of the League, and Mr. Ben Read.

B. M. Robertson, *Chairman of Publicity.*

⁂

Orange County

More than twenty-five members of the Woman's Auxiliary to the Orange County Medical Association met at the home of Mrs. Harry G. Huffman.

The Huffman home was beautifully decorated with dahlias of all varieties, sent from the famous dahlia gardens of Dr. and Mrs. G. Emmett Raitt.

Mrs. K. H. Sutherland, new president of the group, conducted a short business meeting, at which she introduced her new fellow officers, including Mrs. D. C. Cowles of Fullerton, vice-president; Mrs. L. E. Wilson of Santa Ana, treasurer; and Mrs. G. E. Raitt of Santa Ana, secretary.

Mrs. E. H. Kirsten of Anaheim, program chairman, introduced Mr. Ben Read, executive secretary of the

Public Health League, who discussed pending legislation. Miss Kate Rea of Anaheim, southern district chairman of education of the Federated Women's Clubs, also spoke briefly on proposed amendments.

Other prominent guests introduced to the doctors' wives included a group of San Diego women, all Auxiliary officials. They were Mrs. A. J. Thornton, state president; Mrs. W. H. Newman, state corresponding secretary; Mrs. T. J. Lindemulder, president of the San Diego Auxiliary; and Mrs. C. E. Howard, past president of the San Diego Auxiliary.

At the conclusion of the afternoon's program, Mrs. Huffman served a delicious tea course, with the assistance of her cohostesses, Mrs. Dexter Ball, Mrs. R. C. Harris, Mrs. K. H. Sutherland, and Mrs. G. E. Raitt.

Sacramento County

The regular meeting of the Sacramento Medical Auxiliary was held at the home of Mrs. Hilding Johnson at 8 p. m., September 15.

The minutes of the last meeting were read and approved. Mrs. Brown announced that Mrs. Edward Babcock had been appointed to serve on a board of directors to replace Mrs. Brendel, who has moved to Berkeley.

Letters were read from the secretary of the Community Chest and the Braile Publishing Company thanking us for our donations.

Mrs. Scatena gave the treasurer's report as follows: Savings account, $77.39; commercial account, $99.08.

Mrs. Krull gave the report on work being done at the library at the County Hospital, which now has 304 books and which is well supplied with magazines.

Mrs. Brown reported on work that had been done for the Red Cross during the State Fair. The women served at the booth for lost children at the Fair. Mrs. E. D. Edson told us of the campaign being conducted by the Tuberculosis Association to give skin tests to all school children.

Following the business meeting we were entertained by a review on new books.

Mrs. John D. Lawson.

San Francisco County

The next several meetings of the Woman's Auxiliary of the San Francisco County Medical Society will be luncheon meetings. The first will be held at the Western Women's Club on November 17, at which time we will have as guest speaker, Dr. Ray Lyman Wilbur. The December 8 meeting, also to be held at the Western Women's Club, will have as its speaker Mrs. A. C. Reed, who will give a book review on "My Great Wide Beautiful World" by Juanita Harrison.

At present the round-table discussions, held on every Wednesday morning at the County Medical Society building, are claiming the interest of the members.

Santa Barbara County

The Woman's Auxiliary to the Santa Barbara County Medical Society has been bending all its energies this fall to the plans for a Health Institute, to be held on October 23 and 24. At each meeting, plans have been discussed and suggestions made and committees appointed. Mrs. Richard McGovney is general chairman for Arrangements; Mrs. John Van Paing, chairman of Exhibits; Mrs. Charles S. Stevens, chairman of Hostesses; Mrs. Horace Pierce, Decorations; Mrs. H. E. Henderson, Publicity. Mrs. Edward Markthaler and Mrs. Frank Hombach have given especial assistance to Mrs. McGovney in personal contacts with coöperating agencies and financial arrangements.

On September 4 the president, Mrs. William R. Hunt, entertained the members of the Board at luncheon at her home, when plans for the year's work were made. The first regular meeting of the year was at the home of Mrs. Richard McGovney, following a barbecue luncheon. It was decided to hold the monthly business meetings on the first Wednesday morning of the month at the Public Library, after which those members who so desire may attend the luncheon meeting of the Health Section of the County Council of Social Agencies. In this way duplication of programs will be avoided.

A pleasant social function was the dinner in Santa Maria on October 12, at which the doctors' wives from Santa Barbara met several from Santa Maria and several from San Luis Obispo County. The occasion was a joint meeting of the Santa Barbara and San Luis Obispo County Medical Societies at the Santa Maria Club, their wives dining at the Santa Maria Inn. No formal meeting was held, but the ladies from the North were told of the activities of the Santa Barbara doctors' wives, with whom they have not heretofore joined.

This meeting followed the regular October monthly business meeting on Wednesday, the 7th, at the Public Library at 10 a. m. The business centered around plans for the Health Institute, which were outlined by the chairman, Mrs. Richard McGovney.

⁂

The regular monthly business meeting of the Santa Barbara Auxiliary was held in the Board Room of the Public Library at 10:30 o'clock, November 4, nine members being present. Reports were given of the Health Institute, which was held on October 24 and 25. They showed a balance of about $50 of receipts over disbursements, and it was agreed to put this into a special fund to start the next Health Institute with. Letters of thanks have been written to all agencies and persons coöperating, and suggestions were made for improvements to be made another year. Plans were announced for the membership tea, to be given by one of our members at her home on November 20, to which the wives of all doctors and internes in the county will be invited. Invitations are to be mailed to all, and then all are to be called on the telephone in order that members may take nonmembers to the tea in their cars.

Eight members took part in the Red Cross membership drive on November 12. The president, Mrs. William R. Hunt, entertained at tea on November 5 all Health chairmen in the Parent-Teacher Association Council, when she impressed on them the importance of each school taking a subscription to *Hygeia,* and also the importance of at least one Health program in each Parent-Teacher Association every year. The superintendent of schools and the school physician are coöperating in the *Hygeia* campaign. Our president is Health chairman for the Parent-Teacher Association Council in Santa Barbara.

Elisabetta P. Henderson, *Publicity Chairman.*

Santa Clara County

The Board of Directors met previous to the regular meeting, to pay bills; elect a new corresponding secretary; fill a vacancy on the Board—one member resigning; and hear the report of the chairman of the Auditing Committee.

The regular meeting was a luncheon held at the San Jose Country Club, forty-two members being present.

After routine business was disposed of, Mrs. Shepherd gave a report of the State Board meeting held in Santa Monica in September.

The guest speaker for the day was Mrs. William P. Butler, who spoke on *Impressions of Modern Medical Literature.*

* * *

Report of the regular meeting of the Woman's Auxiliary to the Santa Clara County Medical Association.

The meeting was an informal musicale and tea held at the St. Claire Hotel on November 2. Forty members were present.

Routine business was disposed of and at which time it was voted to sponsor a tea in honor of the Santa Clara County Nurses' Association, November 25.

A half-hour of informal music was presented by a trio of young people, after which tea was served.

Mrs. Daniel Bilker, *Secretary.*

MISCELLANY

Under this department are ordinarily grouped: News Items; Letters; Special Articles; Twenty-five Years Ago column; California Board of Medical Examiners; and other columns as occasion may warrant. Items for the News column must be furnished by the fifteenth of the preceding month. For Book Reviews, see index on the front cover, under Miscellany.

NEWS

Coming Meetings

California Medical Association, Del Monte, May 2-5, 1937. F. C. Warnshuis, M. D., 450 Sutter Street, San Francisco, secretary.

* * *

Western Surgical Association, Kansas City, Missouri, December 11-12. A. H. Montgomery, M. D., 122 South Michigan Boulevard, Chicago, secretary.

Medical Broadcasts*

American Medical Association

The American Medical Association and the National Broadcasting Company are presenting the second series of dramatized health broadcasts, under the title "Your Health." The first broadcast in the new series, the thirty-second dramatized coöperative broadcast under the title "Your Health," was given October 13. The theme for 1936-1937 differs slightly from the topic in the first series, which was "Medical Emergencies and How They Are Met." The new series is built around the central idea that "one hundred thousand American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve the American people in sickness and in health."

The program will be on the Blue network instead of the Red, as originally announced.

The topics are announced monthly in advance in *Hygeia,* the health magazine, and three weeks in advance in each issue of the *Journal of the American Medical Association.*

The time of the broadcast is Tuesday afternoon, two o'clock, Pacific time.

* * *

San Francisco County Medical Society

A radio broadcast program for the San Francisco County Medical Society for the month of December is as follows:

Tuesday, December 1—KYA, 6 p. m.
Tuesday, December 8—KYA, 6 p. m.
Tuesday, December 15—KYA, 6 p. m.
Tuesday, December 22—KYA, 6 p. m.
Tuesday, December 29—KYA, 6 p. m.

* * *

Los Angeles County Medical Association

The radio broadcast program for the Los Angeles County Medical Association for the month of December is as follows:

Tuesday, December 1—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, December 5—KFI, 9 a. m. Subject: The Road of Health.
Saturday, December 5—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, December 8—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, December 12—KFI, 9 a. m. Subject: The Road of Health.
Saturday, December 12—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, December 15—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, December 19—KFI, 9 a. m. Subject: The Road of Health.
Saturday, December 19—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, December 22—KECA, 10:30 a. m. Subject: The Road of Health.
Saturday, December 26—KFI, 9 a. m. Subject: The Road of Health.
Saturday, December 26—KFAC, 10:15 a. m. Subject: Your Doctor and You.
Tuesday, December 29—KECA, 10:30 a. m. Subject: The Road of Health.

The San Francisco Medical History Seminar.—On November 18, 1936, the San Francisco Medical History Seminar gave a luncheon in honor of Dr. Maude E. Abbott, Curator of the Medical Museum at McGill University, Montreal. Doctor Abbott, who has made many important contributions to the history of medicine and nursing, addressed the Seminar on "The Young Osler."

Five States Receive Over Six Million Dollars in Social Security Funds. — The Federal Social Security Board, under date of October 28, announces: Federal grants totaling $6,824,239.30 to Alabama, California, Massachusetts, South Dakota, and New Jersey for assistance to the needy aged, the blind, and to dependent children were announced by the Social Security Board recently.

The states receiving funds, the amounts granted, and the number of persons who, it is estimated, will be helped are shown in the following table:

State	Aid to	Federal Grant	Estimated Number of Persons to Receive Aid
Alabama	Aged	$ 241,412.59	12,000
	Children	71,735.73	17,500
California	Aged	3,858,435.00	53,900
	Blind	209,506.50	4,300
	Children	409,825.50	22,300
Massachusetts	Aged	1,740,945.24	27,800
	Blind	26,158.82	1,050
South Dakota	Aged	249,889.50	7,933
New Jersey	Blind	16,330.42	494
Total		$6,824,239.30	147,277

The grants-in-aid to Alabama, California, Massachusetts, and South Dakota present the federal share of the states' public-assistance expenditures for the current quarter, October 1 to December 31.

During October, it is estimated that 1,362,189 individuals—989,532 aged, 29,721 blind, and 342,936 dependent children—will be aided in the forty-three states now operating one or more plans under the federal-state public-assistance program. The Social Security Board has approved forty-two state plans for aid to the needy aged, twenty-six state plans for aid to the needy blind, and twenty-seven state plans for aid to dependent children in their own homes.

Under these plans, approximately half the cost of the states' aid to the aged and blind and one-third the cost of the states' aid to dependent children is paid by the Federal Government. Since February a total of $87,757,130.27 of federal funds has gone to coöperating states to aid them in financing their approved state programs for these three forms of assistance. Of this amount $78,162,444.78 was for the aged, $2,923,753.29 for the blind, and $6,670,932.20 for dependent children.

---

* County societies giving medical broadcasts are requested to send information as soon as arranged (stating station, day, date and hour, and subject) to California and Western Medicine, 450 Sutter Street, San Francisco, for inclusion in this column.

Colorado State Medical Society.—The Executive Committee and the Advisory Board of the Colorado State Medical Society jointly have fixed July 19, 20, and 21, 1937, as the dates for the Rocky Mountain Medical Conference.

The Rocky Mountain Medical Conference is to be a joint meeting of the Colorado State Medical Society, the New Mexico Medical Society, the Utah State Medical Association, and the Wyoming State Medical Society, to which members of the recognized societies of adjoining states will also be invited.

California Department of Industrial Relations.—The last report to the Governor's Council contained the following item:

Division of Immigration and Housing.—During the month of August, 66 labor camps were inspected; 15 camps were listed as good, 26 fair, and 25 bad. Of the total number of camps inspected, 54 were old camps and 12 new ones. In the camps inspected it was found that 2,302 occupants were American-born, while 748 were foreign-born, making a total of 3,050, of which 1,567 were men, 766 women, and 717 children.

During the month 44 automobile camps were inspected; 26 were listed as good, 11 fair, 4 bad, and 3 closed. Ten housing inspections were made.

A considerable portion of the month was taken up with matters having to do with proposed changes to the State Housing Law. This work has necessitated much careful study and thought, not only to the proposed changes themselves, but to the planning of a campaign designed to bring about their adoption in the Legislature without any major opposition. This has meant much correspondence and the holding of many conferences with individuals and groups who are favorable to our work. The proposals are now ready for mimeographing and will be distributed shortly for criticism. The main features have been discussed with the Attorney-General's office and received verbal approval.

Lactic Acid From Whey.—Lactic acid, a chemical used largely in the leather and textile industries, was first identified 150 years ago in sour milk and has been made in the United States for fifty-five years or more, but surprisingly it has never been made commercially from milk until within the last year.

Recently, at the Dairy Industries Exposition at Atlantic City, New Jersey, scientists of the United States Bureau of Dairy Industry demonstrated methods they have developed for making lactic acid and related chemicals from whey.

Whey, a byproduct from cheese and casein manufacture, has been considered for years one of the greatest sources of trouble and waste in the dairy industry. Dairy scientists have long felt there were great possibilities for a new industry within the dairy industry, based on fermenting the milk sugar contained in the whey. A few years ago the Bureau developed the fundamental information for making lactic acid commercially, and has since made further refinements in its process. Last year a large dairy organization handling enormous quantities of surplus milk began making lactic acid and calcium lactate from whey on a commercial scale. The whey in this case is a byproduct from the manufacture of casein from skim milk.

Materials most commonly used for the production of lactic acid at present are molasses, cornstarch, and other sources of fermentable sugar. Lactic acid not only has many uses itself, but it is the material from which other chemicals may be made. Its chief use perhaps is in the leather industry, where its function is to neutralize the lime used in removing the hair from hides. It also is used in the textile industry, in baking, in hardening pickles, in medicinal preparations, and in beverages sold at soda fountains. Some of the chemicals made from lactic acid are useful in making lacquers.

Recently, the Bureau scientists have shown how lactic acid may be concentrated to a greater degree than it is at present. Instead of an acid containing from 50 to 75 per cent water, plus some impurities, producers are now enabled to make an acid containing no water and fewer impurities. This applies to lactic acid made from the usual materials as well as to that made from whey.

Medical Stamp Exhibit.—A special exhibit of postage stamps relating to medicine has been arranged in the University of California Medical School Library. It includes some seventy-five items, mostly from the collection of Dr. K. F. Meyer, Director of the Hooper Foundation for Medical Research, who is an ardent philatelist. Many countries have issued stamps commemorating medical events or physicians of prominence. Nearly all of these are on view in the exhibit. It is believed that this exhibit is the first of its kind to be assembled.

Southern California Medical Association.—The ninety-fifth semiannual meeting was held Friday and Saturday, October 30 and 31, at the permanent quarters building of the Los Angeles County Medical Association, 1925 Wilshire Boulevard, Los Angeles.

The program follows:

October 30—Friday Afternoon Session

Immediate Repair of Divided Nerves and Tendons of the Hand—J. Edwin Kirkpatrick, M. D., Los Angeles.
Discussion by Paul E. McMaster, M. D., Los Angeles; Hugh Toland Jones, M. D., Los Angeles.

Normal Hematologic Standards with Discussion of Variations Due to Physiologic Changes—A. G. Foord, M. D., Pasadena.
Discussion by W. M. Butt, M. D., Los Angeles; J. W. Budd, M. D., Los Angeles.

What May We Expect From the Treatment of Tumors of the Bladder—H. C. Bumpus, Jr., M. D., Pasadena.
Discussion by J. J. Crane, M. D., Los Angeles; A. J. Scholl, M. D., Los Angeles.

Proctology in General Medicine—C. N. Taylor, M. D., Los Angeles.
Discussion by A. J. Murietta, M. D., Los Angeles; W. H. Kiger, M. D., Los Angeles.

Friday Evening Session

Protamine Insulin and the New Era in Diabetes—Elliott P. Joslin, B. A., Ph. B., M. A., M. D., F. A. C. P., Clinical Professor of Medicine, Harvard Medical School.

October 31—Saturday Morning Session

Medical Aspects of the Business Cycle—Emil Bogen, M. D., Olive View.
Discussion by Phoebus Berman, M. D., Los Angeles; Reginald Smart, M. D., Los Angeles.

Results of Surgical Treatment of Hyperparathyroidism—Isaac Y. Olch, M. D., Los Angeles.
Discussion by C. J. Baumgartner, M. D., Los Angeles; C. S. Sturgeon, M. D., Los Angeles.

Anemia as a Cause of Angina Pectoris—Francis M. Smith, M. D., La Jolla.
Discussion by Franklin R. Nuzum, M. D., Santa Barbara; J. F. Anderson, M. D., Los Angeles.

General and Neurosurgical Consideration of the Cerebral Birth Palsies—Hans V. Briesen, M. D., Los Angeles.
Discussion by George H. Patterson, M. D., Los Angeles; John C. Wilson, M. D., Los Angeles.

Saturday Afternoon Session

Gastroscopy as an Aid in the Diagnosis of Malignant Lesions of the Stomach—John P. Renshaw, M. D., Los Angeles.
Discussion by Roland Cummings, M. D., Los Angeles; John C. Ruddock, M. D., Los Angeles.

Cesarean Sections in Los Angeles County—William Benbow Thompson, M. D., Los Angeles.
Discussion by H. K. Marshall, M. D., Glendale; Lyle C. McNeile, M. D., Los Angeles .

Allergic Study of Feather Protein—George Piness, M. D., Los Angeles.
Discussion by P. A. Gray, M. D., Santa Barbara; Robert W. Lamson, M. D., Los Angeles.

The Relationship of Low Basal Metabolic Rates to Allergic Diseases—Merrill W. Hollingsworth, M. D., Santa Ana; John Montanus, M. D., Santa Ana.
Discussion by Hyman Miller, M. D., Los Angeles; Francis Pottenger, Jr., Monrovia.

New Welfare Set-Up to Head All Relief Is Asked for State.—The creation of a State Department of Public Welfare to administer all phases of indigent, veterans, unemployment and transient relief, assistance to the aged and the blind and aid to dependent children, is suggested in a survey of welfare conditions in the State just completed by the Bureau of Public Administration of the University of California. The details of the survey, which covered several years' time, is included in a volume "Welfare Activities of Federal, State and Local Governments in California, 1850-1934." The survey was made by Frances Cahn, research associate, and Valeska Bary, former research associate in the Bureau, and is a complete record of public welfare work in the State from the coming of the Argonauts to the present day.

The new department is needed to obviate the present "lack of coördination of activities and a resultant duplication of effort and increased expenditures" occasioned by the present various state and county set-ups for relief and other aid. The present Department of Social Welfare, Department of Institutions, and Department of Military and Veterans' Affairs are held to ramify into each other to some extent. The survey points out that there is also need for the Department of Social Welfare and the different counties to establish comparable relief standards, policies, and methods.

The new department should likewise be given the right to license and supervise all private institutions for the aged and the mentally disordered, and should be given supervision of all county hospitals and almshouses, the survey states. It should also be given the supervision of all public and private child welfare activities, such as boarding homes, institutions, day nurseries and child-placing agencies and the supervision of adoptions, juvenile probation and parole and the operation of State correctional schools. While it would grant the counties autonomy in the administration of their welfare activities, it is suggested that such activities be made to conform to the minimum requirements set up by the new department, and by federal relief standards.

Population in the United States to Reach Peak in 1950 and Then Decline.—A declining national population is inevitable within fifteen years unless the birth rate should rise or immigration increase, according to Dr. O. E. Baker of the Bureau of Agricultural Economics.

"The birth rate has declined more than 25 per cent during the last ten years. If the birth rate continues to decline at this rate," Doctor Baker says, "a maximum population will be reached by 1945 or 1950. Thereafter, the population will decline; declining slowly at first, then at an accelerating rate."

A declining national population, with rural surplus and urban deficit in births, will have serious economic and social consequences in Doctor Baker's opinion.

These consequences will develop slowly and silently, he predicts, adding that it probably will be twenty-five years before many people will realize what is taking place.

"Fifty years from now," Doctor Baker says, "there may be only a third as many children in the nation as now, and only half as many women of child-bearing age. There will be nearly three times as many old people. Many unemployed urban people will seek shelter and sustenance with relatives and friends on farms. Many of these people will start little farms, and never again return to the cities to reside.

"Millions of farm youth will migrate to the cities, many of these migrants will inherit farms, or, through the settlement of estates, acquire mortgages on farms. Wealth—represented by the ownership of land or the income from it—will be transferred to the cities."

Doctor Baker says that other millions of farm youth will begin farming, mostly on farms vacated by the death of aged farmers. Unless these farms are acquired by inheritance, he declares, there will be an increasing number of tenants.

But there is a way to retard these ominous developments, in the opinion of this economist. "They can be retarded," he says, "by a rapid decentralization of population, industry, and commerce, by the spread of part-time farming, and by an appreciation by the middle and upper classes of their responsibility for the reproduction of the race and the welfare of the nation."

The History of Science Dinner Club of Berkeley.—Dr. Herbert Evans, who organized the very stimulating History of Science Dinner Club in Berkeley, has arranged a program for this winter which carries along the general theme of last year's discussion. Special emphasis was placed last year on the relations of science and philosophy in the eighteenth and early nineteenth centuries. This year the latter part of the nineteenth century will be included. A consistently pleasing feature of the meetings has been an informal display of rare and interesting scientific literature.

Neutron Radiation Proves Effective on Mouse Sarcoma.—Joint experiments conducted by the Yale University Department of Internal Medicine and the University of California have determined that neutron radiation is four times as effective as the x-ray in the experimental destruction of mouse sarcoma 180, a cancerous-like growth, but that much remains to be developed regarding the action of such radiation on the healthy tissue.

The experiments were conducted for the University of California by Professor Ernest O. Lawrence, director, and Paul C. Aebersold, assistant in the Radiation Laboratory of the University of California, and Dr. John H. Lawrence of the Department of Internal Medicine, Yale University.

"It was the primary purpose of this investigation to determine relative doses of both neutron rays and x-rays required to kill mouse sarcoma 180," the statement covering the experiments declares. "In other words, these experiments were concerned with dosage ratios rather than absolute values. It was a question only of comparing the radio sensitivity of the tumor with that of the healthy mouse for the two kinds of radiation.

"It was generally noted that with the higher doses of neutron the tumors grew less rapidly when compared with tumors irradiated with equivalent doses of x-rays. Thus, from the results it appears that neutrons produce the same lethal effect with one-quarter the x-ray dose. The experiments do not allow us to arrive at any broad conclusions."

The sarcoma group of tumors are held to be equally as malignant and as destructive as the cancer or carcinoma group, but still lack the generic designation, such as cancer. The outcome of the experiment, while indefinite, prompted the statement by its authors that "if further studies on this tumor and other animal tumors bear out present indications, then we have here a new form of radiation which may have important clinical applications."

The experiments were made possible by the support of the Joseph Macy, Jr., Foundation, the Research Corporation, and the Chemical Foundation of America. The findings were submitted to the National Academy of Sciences and published by that organization.

What They Do.—Each year, from Thanksgiving to Christmas, Americans from Maine to Hawaii and from Alaska to Florida unite with the people of forty-one other countries in one of the most powerful mass movements against a common foe that the world has ever known—tuberculosis.

Voluntarily they participate in the annual sale of Christmas Seals, those gay holiday stickers on which appears that international symbol of health and hope—the double-barred cross. This year the United States Seals also bear the picture of jovial good health personified, Santa Claus.

Christmas Seals, since 1907 when the first one was sold in Wilmington, Delaware, have raised funds—penny by penny and dollar by dollar—that have helped to build a line of defense that protects all of us.

That the defenses are effective is shown clearly by the fact that the tuberculosis death rate has been forced down from 179 deaths per 100,000 population in 1907 to fifty-four in 1935.

Against the unnecessary toll taken by this communicable, preventable and curable disease, the comparatively small sums of money raised in local communities by voluntary groups have been used in those communities with a definite plan, under the guidance of the National Tuberculosis Association.

These funds have promoted the establishment of agencies of various kinds that have in turn been chiefly instrumental in gradually bringing tuberculosis under control. These lines of defense may be catalogued briefly thus:

1. Twelve hundred institutions—sanatoria for tuberculosis and hospitals having tuberculosis departments—providing 95,000 beds for the treatment and prevention of tuberculosis, chiefly for adults.
2. Ten thousand public health nurses engaged in tuberculosis work.
3. One thousand clinics for diagnosing and finding tuberculosis.
4. More than 1,200 preventoria, summer camps, open-air schools and similar institutions for the care and treatment of children with various forms of tuberculosis or for those who have been in contact with tuberculosis, or who are subnormal physically.
5. One thousand nine hundred and eighty-one tuberculosis associations, including a state-wide organization in every state and local agencies in all of the larger population centers.

But the building of our national defense against tuberculosis is not completed. The disease still takes the lives of about 70,000 persons annually in the United States. Tuberculosis, although ranking seventh as a cause of death when all ages are considered, is the leading killer of people between 15 and 45. It remains the breaker of homes, the maker of orphans, and a constant threat to the life and happiness of everyone.

Hotis Test Is New Weapon Against Dairy Cow Disease.—A new test which promises to be a useful means of detecting mastitis, a troublesome and costly disease of dairy cattle, has been developed by research workers of the United States Department of Agriculture. The new method is known as the "Hotis test," named after its originator, R. P. Hotis of the Bureau of Dairy Industry, who died soon after conducting most of the experimental work.

Although the method has been applied only on a limited basis thus far, Department officials plan to give it practical field tests to determine its adaptability under various conditions, for the diagnosis of mastitis in dairy herds. A simple accurate test for the detecton of this disease in its early and latent stages has long been sought.

Mastitis, especially in dairy cows, has been a problem for many years. It is a disease of the milk glands which often results in abnormal milk and changes in the udder tissue in the animals infected. Large numbers of cows have been slaughtered because their udders have been so badly damaged as to make them unfit for milk production. The trained veterinarian or inspector can often detect this disease by clinical symptoms that are apparent to the eye, or by careful examination with the hands. But there are certain early and latent stages in which the udder may be infected with the causative organisms, and yet a definite diagnosis may be difficult or impossible under usual methods.

A number of laboratory tests have been used to indicate such abnormal milk. Such tests include the direct microscopic examination, leukocyte count, chlorid test, brom-thymol-blue test, catalase test, and bacteriologic culture methods on certain differential media. Usually two or more of these tests have been used together, as one test may show a reaction where others fail.

The new test brought out by the Bureau of Dairy Industry is believed to be more accurate than any other heretofore used. In addition, it is comparatively simple and requires little equipment, thus allowing the handling of a large number of samples at one time.

By the use of this test it appears that incipient or latent infections with the mastitis streptococcus may be quickly detected. This will allow segregation of the infected animals and permit prompt methods to prevent spreading. Infected cows should be milked last, and the milker should rinse his hands in a chlorin solution after milking each cow. If milking machines are used, the teat cups should be rinsed thoroughly with water, then with a chlorin solution, before they are placed on the next animal.

LETTERS

Concerning automobile injuries.

Westways*

November 2, 1936.

To the Editor:—I thank you for sending me the copy of California and Western Medicine.

I think I need not tell you that none is more aware of the deplorable accident situation in the United States today than the Automobile Club of Southern California. We have studied the problem for many years and have considered it from every possible angle. The point of view that there are entirely too many incompetent drivers operating motor vehicles today is probably the most generally accepted reason for the high casualty rate. How to eliminate these unfits is a problem that, from its practical aspects, is a most difficult one.

The existing law requiring physical examinations has many glaring defects. Were it to be rigidly and impartially enforced it would still fall far short of proving a noteworthy correctional measure. This is because of the fact that it makes no provision for testing the psychological as opposed to the physiological qualifications of the driver. There are many of us who believe that the mentally unfit (temporarily or otherwise) are probably responsible for more accidents than the physically unfit. In the class of the mentally unfit will be found the "repeater," who is the cause of accident after accident. He may be of the emotionally unbalanced type, a victim of delusions or a sufferer from any one of many neurological ailments which prevent rapid reactions in times of emergency. The present law doesn't touch this type of individual, and yet we all know that he is a distinct menace to himself and to his fellow motorists. When we have devised a means for determining those who are congenitally disposed toward accidents and can take them out from behind the wheels of motor vehicles, we shall have gone a long way toward solving the accident problem.

I noted with interest your relative figures as to the geographical accident localities. Without being captious I think the per capita method of rating accidents is hardly fair. We have practically abandoned it, for we feel that gasoline consumption is a more equitable gauge for measuring the relative hazards in various areas. And there is considerable difference between two scales of measurement. On the basis of gasoline consumption, for instance, we find that the national average death rate in 1935 was 22.8 deaths per 10,000,000 gallons of gasoline consumed. The lowest rate prevailed in Rhode Island, where it dropped to 10.2; the highest in Georgia, where it reached 35.4. By this basis of calculation the California figure was 20.9—not an enviable record by any manner of means, but yet somewhat below the national average. Unfortunately we do not have these figures for various cities. It would be interesting to compare them with the per capita death rate.

Again I want to thank you for sending me your publication, which has proven of great interest to me.

Very sincerely yours,

Phil Townsend Hanna,
Editor and General Manager.

Concerning legal jurisdiction of district coroners.

State of California
legal department

San Francisco, October 23, 1936.

Honorable Walter M. Dickie,
Director of Public Health,
313 State Building,
San Francisco.

Dear Sir:—In your communication of September 17, 1936, you state that a seaman died aboard the steamer *S. C. T. Dodd* as it was being untied from a pontoon wharf at Estero Bay, San Luis Obispo County, California.

---

* Owned and published monthly by the Automobile Club of Southern California.

According to your statement a physician of that county pronounced the man dead without evidence of external violence.

The boat proceeded to Richmond, and the coroner of Contra Costa County was notified the body of the deceased was aboard the ship. The remains were taken in charge by the coroner and, after inquest, a verdict as follows was returned:

> Coronary occlusion, and we further find no censure due the captain of said boat in bringing the body to Richmond dock, owing to the difficulties attendant on removing body to shore at Estero Bay, California.

A death certificate was issued in Contra Costa County, a copy kept in the Richmond Health Office, and the original filed in your Bureau of Vital Statistics in Sacramento.

The remains were taken in charge by the authorized representative of the Sailors' Union in San Francisco and are no longer available for autopsy by the coroner of San Luis Obispo County, if, indeed, it was under the circumstances his duty to conduct an autopsy and issue a certificate of death upon the seaman, who did in fact die in his county.

You state that similar situations frequently occur in San Francisco Bay, where a boat at the exact time of death is in one county, but proceeds to dock in another, and ask the following three questions:

> First: Should the certificate filed by the coroner of Contra Costa County be permitted to stand alone on our official record?
>
> Second: Has the coroner of San Luis Obispo County jurisdiction to issue a death certificate from his county? In this connection, I would state that the body is not available for autopsy by such coroner.
>
> Third: Should a certificate of death be issued by the coroner of San Luis Obispo County, and should it be attached to the certificate of death already filed from Contra Costa County. It occurs to me that the answer to this question is extremely important to the State due to the geographical contour of California.

In reply, I would first agree that the geographical contour of California should be considered in reaching a conclusion as to the questions asked by you.

Waters three miles seaward are within the boundaries of this State (*Ocean Industries* vs. *Superior Court,* 200 Cal. 235). A death might occur at many points within this limit where it would be impossible to land a vessel and permit a body to be taken to the county seat of the county in which the man actually died, nor would the law demand that a vessel postpone a voyage for the purpose of permitting a local autopsy.

In the matter under consideration it definitely appears that though a physician of San Luis Obispo County was able to board the ship at the pontoon wharf at Estero Bay, there were difficulties attendant upon removing the body to shore.

Under such circumstances we conclude it was the duty of the coroner of Contra Costa County to take possession of the deceased's body within the purview of Section 5 of the Vital Statistics Act, Chapter 378, Statutes of California, 1915. Certainly, as far as he was concerned the death occurred in this State and the body was found in his county.

The matter is somewhat akin to that discussed in *Huntly* vs. *Zurich etc. Co.,* 100 Cal. App. 201, at 214, where the Court said:

> The evidence offered by plaintiff shows that no inquest was held in Los Angeles County. The performance of an autopsy was not the holding of an inquest. It also shows that upon the arrival of the body in San Francisco plaintiff was dissatisfied with the findings of the autopsy surgeon in Los Angeles; that she represented that her husband's death was sudden; that he had had a "terrible fall." She further expressed the idea that his death had been occasioned by violence of some sort and was not the result of natural causes. Under the circumstances, the body being within the city and county of San Francisco, and within the jurisdiction of the defendant, Leland, and he having been informed that no inquest had been held in the county of Los Angeles, and there being a question as to the cause of death as expressed by the plaintiff, the coroner acted within his authority in ordering an inquest held, and in authorizing his autopsy surgeon to proceed in the usual manner.
>
> The decision of the question as to whether an inquest is necessary rests in the sound discretion of the coroner, and there is nothing in the record to counteract the presumption that he regularly performed his duty as coroner. . . .

Your first question is answered in the affirmative and your second and third in the negative.

The law does not demand the impossible. As the coroner of San Luis Obispo County did not have possession of the body and could not get the same, it was properly examined and disposed of in Contra Costa County. The coroner of the first-named county cannot possibly add further to the information already on file in the Bureau of Vital Statistics.

Very truly yours,
U. S. Webb, *Attorney-General.*
By Lionel Browne, *Deputy.*

SPECIAL ARTICLES

MEDICAL JURISPRUDENCE*

By Hartley F. Peart, Esq.
San Francisco

Malpractice Liability of Physicians Employed in State, County, or Other Publicly Owned Hospitals: Absence of Liability of State, County, or Other Governmental Agency.

On November, 4, 1936, the Attorney-General of the State of California rendered the following significant opinion to Colonel Nelson M. Holderman, Commandant of the Veterans' Home of California:

> Dear Sir:—I have before me your communication under date of October 20, 1936, which is as follows:
>
> "I have been instructed by the Board of Directors of the Veterans' Home of California to direct you a communication requesting an opinion as to whether or not any suit of malpractice or damages could be brought against our surgeon or assistant surgeons by any dissatisfied member of the Home."
>
> I am aware of no reason why a surgeon or assistant surgeon at the Veterans' Home of California should not be subject to suit for malpractice or damages by a dissatisfied member of the Home, or by any other person.
>
> Whether or not a judgment could be secured against such surgeon or assistant surgeon in any such action would, of course, depend upon the facts in the particular case.
>
> Assuming that the basis of the inquiry which you present upon behalf of the Board of Directors of the Home is for the purpose of ascertaining whether or not there is any exemption from suit extended to such surgeon or assistant surgeon, your question should be answered in the negative.

The Attorney-General's opinion suggests the important question: What is the liability of a physician employed in a county hospital, state hospital, asylum or home, or in a municipally owned hospital for negligence (*i. e.,* malpractice)? It also raises another question: If a physician employed in a state, county or municipally owned hospital is negligent in his treatment of a patient therein, is the governmental agency that owns the hospital liable to a civil action for damages brought by the patient?

The Attorney-General's opinion reaches the conclusion that a physician employed in a state-owned institution is legally responsible for malpractice with respect to any patient therein to whom he may negligently render professional services. In other words, a physician employed by a governmental agency to render professional services to patients furnished by the governmental agency is just as liable to be sued for malpractice as a physician who is engaging in private practice and renders professional services to his own private patients. The Attorney-General's opinion is in accord with the general law on this subject. In Volume 21 of California Jurisprudence at page 908, we find the following statement of the law:

> It is elementary that a public officer is liable to respond in damages to one specially injured by his negligence or

---

*Editor's Note.—This department of California and Western Medicine, containing copy submitted by Hartley F. Peart, Esp., has been established by the California Medical Association Council. Each issue will contain excerpts from and syllabi of recent decisions and analyses of legal points and procedures of interest to the profession. These will be compiled by Mr. Hartley F. Peart, General Counsel of the Association.

refusal to perform, or by his negligent performance of an official ministerial duty to the extent of such special injury, regardless of intentions, whether good or bad.

Generally speaking, physicians who render professional services on behalf of the State or a county or municipality are considered to be "public officers." Also, generally speaking, this is so even though the professional services are rendered gratuitously.

One would suppose that since the employee, that is to say, the physician, is liable for malpractice, that his employer, in this case the state or a county or city, would also be liable to respond in damages to the injured patient. Curiously enough, however, in those cases in which the question of the Government's liability has been considered, the courts have held that neither a state, county nor city is liable for the malpractice of a physician employed by such state, county or city. In *Sherbourne* v. *Yuba County*, 23 Cal. 113, an attempt was made to hold a county liable to one who, while an inmate of a county hospital, suffered injuries from unskillful treatment by the resident physician. It was held, however, that a county is not liable for acts of officers or employees which it appoints in exercise of a portion of the sovereign power of the State by the requirement of a public law simply for the public benefit and from which the county as a corporation derives no pecuniary gain. Again in *Davie* v. *Regents of the University of California*, 66 Cal. App. 689, it was held that the regents were not liable for the malpractice of an attending physician at the University Infirmary, following the rule of the *Sherbourne case*. The court concluded its opinion with a statement that although it was unfortunate, nevertheless the injured plaintiff must be left to his remedy against the attending physician for malpractice.

There are cases in which it is suggested that the immunity from suit for malpractice of the state, a county or city, would not exist if the injury resulted from an activity upon the part of the governmental agency in a proprietary, as distinguished from a governmental, capacity. However, there are no cases in which it has been held that the operation of a state hospital or institution or county hospital or municipal hospital or clinic is a proprietary function, and it seems very doubtful that such a case will ever occur, inasmuch as the protection of health is within the police powers of all governments and as such is a governmental function.

If the malpractice burden which now is borne by those physicians in governmental employment is to be shared by the state, counties or cities, or is to be shifted from the physicians to their employers, it must be accomplished by legislative action. It is interesting to note that the California Legislature has provided, with respect to county roads and highways, that liability for the negligence of county road workers shall be upon the county. No good reason occurs to the writer why the Legislature should not also provide the same rule for physicians.

THE BIRTH CONTROL INDUSTRY

An article by Harrison Reeves in the *American Mercury* states:

> The fact that one of America's fastest-growing and most prosperous businesses is conducted brazenly in the face of a thousand laws which specifically forbid its existence, is a paradox that is generally overlooked in the public's scramble to acquire some of that selfsame industry's valuable products. It is not so vast, say, as the petroleum business, because we spend more time riding aimlessly about in motor cars than we do stopping to make love; nor can it be compared in total volume of sales with the cosmetics trade with which it is in several ways allied. It is more notorious than some of America's widely advertised commercial combines because it thrives on free, or word-of-mouth, publicity; moreover, it boasts of widespread intellectual approval and millions of satisfied users. Its cash sales run into hundreds of millions of dollars annually, and its potential profits approach the billion-dollar mark. And yet, as noted above, the private sale of birth-control devices is strictly a bootleg business, prohibited everywhere, including Russia, by the most intricate laws ever devised by the legalistic mind of man.
>
> Strangely enough, little progress has been made in securing the repeal of these laws, and it is likely that less and less effort will be expended in coming years. For the problem can be solved in simpler fashion; and that is by treating the laws as though they did not exist. This is the current procedure in America as well as in the rest of the civilized world, the populace having been sold on the idea that the best way to combat tyranny is, first, to defy it, and then apply force. In the instance of birth control, the force applied is the simple one of large commercial profits. There is a vast amount of money in the business, and it has attracted indubitable talent. These modern entrepreneurs have come to believe, and with reason, that the industry will soon be commonplace and honorable, and that the old taboos will disappear in the same manner as did those once exercised against witches in the puritanical purlieus of Salem, Massachusetts.
>
> From the strictly industrial point of view, the total dollar volume of the birth-control medication and device business in America now approximates $300,000,000 a year. Yet this retail total, fancy as it may seem, does not include the profits derived from the sales of condoms (classically mispronounced term in a republic that knows not of Sir Richard Condom of George III's reign) which are estimated by informed rubber manufacturers at $275,000,000 annually for the 5,000,000 articles manufactured and sold *daily*. The $300,000,000 is spent for jellies, chemicals, pessaries, suppositories, caps, rings, and compounded prescriptions from birth-control textbooks. . . .
>
> The trade, to use a euphonious term, is divided between nine large and some two hundred small manufacturers. No one of the nine leading concerns, of course, can boast anything like the gross sales of the leading condom entrepreneur, whose annual report discloses that he makes and sells 144,000 daily at three for one dollar, representing a total of some 50,000,000 articles retailed each year for, say, $17,000,000. Yet even though he undertakes no advertising or promotional work, his profits are smaller in proportion than those of the jelly manufacturers, and so the scales are kept balanced. . . .
>
> The known, catalogued, and credit-worthy distributing agencies for the trade number about 125,000, comprising the so-called "daily outlet" list of steady customers. These include 64,000 independent drugstores, thirty-five chains of pharmacies with 7,000 shops, 40,000 cosmetic stores and beauty parlors, approximately 150 recognized free clinics for the dissemination of birth-control advice and devices, and several thousand assorted gasoline filling stations, found on every street and highway in the nation. The exact number of these latter dispensaries is still a matter of academic dispute between manufacturers, jobbers, and the oil company executives, who have given the matter deep and restrained study. . . .
>
> II
>
> There is no considerable difference between the various jellies and chemicals now on the market, organically or in degrees of efficiency, while the mechanical contraptions—condoms excepted—are all precisely the same, usually being manufactured by the large concerns for dozens of owners of trade names. Condoms, however, like tires, vary in strength, according to quality and price. In the statistics given here, such articles as douche bags, syringes, diaphragms, and spermotoxins are eliminated, because the prescription of any one by a physician, or their common-sense use without medical advice, may be dictated by conditions other than birth control proper. In fact, if the first two items named were included in the figures, the totals for the trade would be doubled at least. For it is irrefutably true that birth-control insurance is not bought for nothing.
>
> Of proper consideration, however, is the amount of money which might be saved by more widespread use of birth-control machinery. I refer to the nation's abortion bill. It is estimated by the best-informed actuaries—life insurance experts, hospital authorities, and surgeons at one billion dollars a year. Some say two billion. Prices run from $35, which is standard in the Manhattan slums where medical competition is unbelievably brisk, to $1,500 standard for the Gold Coast of Hollywood. The average bourgeois price in New York is $50 and in the smaller county seats, $100. This excepts, of course, the unscrupulous surgeons who charge whatever the traffic will bear or whatever the case can be scared into. . . .
>
> There is another actuarial figure, too, which bears great import for insurance men. It is the death rate created by these simple little operations. In the United States, where the art is not nearly so highly developed nor so well taught as in many other countries, there are annually 15,000 known deaths, verified by autopsy. There are probably an even greater number accepted by coroners as due to appendicitis (the appendicitis death rate is notoriously high among women of noncanonical age) in which the appendix may or may not have been taken out along with the fetus, just as a precautionary measure. . . .

THIRTY YEARS OF CHRISTMAS SEALS

By Elizabeth Cole

In 1907 the first Christmas Seal sale was launched in Delaware by Miss Emily P. Bissell. She raised $3,000 to use toward building a hospital for children ill with tuberculosis. Much has been accomplished since then, and here in brief form are several important links in the nation-wide chain of tuberculosis control that Christmas Seal funds have helped to build.

The National Tuberculosis Association was founded in 1904 by a group of distinguished tuberculosis specialists and interested laymen. Its aim was to study tuberculosis in all its forms and to disseminate knowledge on its causes, treatment, and prevention. From the first, then, the campaign to fight tuberculosis, at that time the leading cause of death, was educational. To stimulate the public in a desire to secure better health machinery was the object, and in only very few instances have Christmas Seal funds ever been used for relief work.

The sixth International Congress on Tuberculosis was held in Washington, D. C., in 1908. This meeting, at which world-famous scientists were present, gave impetus to the whole tuberculosis movement in our country. During the next ten years, tuberculosis associations were formed in practically every state and there are now 1,981 associations affiliated with the National Tuberculosis Association.

In the belief that better health protection for children would result in better health for all communities as a whole, attention was directed toward the establishment of such media as fresh-air schools, preventoria, and toward encouraging early training in the ways of health. Providence, Rhode Island, opened the first fresh-air school in 1908, and in 1909 the first tuberculosis preventorium was established for New York City children at Farmingdale, New Jersey. Other states followed suit, and today there are 173 institutions with provision for children who need preventorium care.

New York, as early as 1909, passed a state law authorizing the building of county tuberculosis hospitals. In 1913 an act in Washington authorized counties in that state to erect sanatoria for the care of its tuberculous and inspired other neighboring states in the Pacific Northwest to undertake organized tuberculosis work. Today there are almost two hundred county tuberculosis sanatoria, besides more than one thousand other federal, state, city, and privately owned institutions providing special care for tuberculosis patients.

A study of tuberculosis in rural areas made by Wisconsin in 1911 revealed that tuberculosis was as prevalent in the country as in the city. This was an unexpected discovery and awakened other states to the need for searching out tuberculosis in their more isolated districts. Michigan was among them and, following a state-wide survey, was first to use a new type of clinic. It was called the "traveling clinic." The itinerant clinics became popular in other states, and were the means of uncovering many cases of tuberculosis. At permanent tuberculosis dispensaries and clinics patients today not only are treated, but they are taught how to get well. These are functioning to the extent of about one thousand.

At Framingham, Massachusetts, a unique health demonstration was established in 1916 to show that, with the coöperation of physicians and citizens, it was possible to control tuberculosis. At the end of the seven-year demonstration the death rate had dropped to thirty-eight per 100,000 population from 121 during the predemonstration decade. Statistical data of untold value were assembled through this study, and the work carried on in Framingham has resulted in similar demonstrations in other communities.

The study of tuberculosis in industry has been another important link in the chain that Christmas Seals have helped to finance. In an effort to emphasize health as a factor in industry the Chicago Tuberculosis Institute in 1911 started a campaign to detect tuberculosis among industrial workers. Other studies on this subject include one in Vermont among granite cutters, completed in 1921. It was found that certain dusty trades are dangerous, and many measures have now been taken to protect these workers against tuberculosis. A recent contribution has been a study of death rates by occupation, to focus attention on the trades in which the tuberculosis hazard is greatest.

In order to carry out one of the aims of the National Tuberculosis Association, namely, the study of tuberculosis, in 1920 a Committee on Medical Research was organized. Because it was financially prohibitive to found a special laboratory for tuberculosis research, the committee organized and coördinated work of individuals and groups and enlisted the coöperation of various university laboratories with their highly trained personnel. These men and women are working diligently to add to our knowledge about the disease and hope that some day a specific cure may be discovered.

Social research, too, has been carried on, and the findings of various studies have helped to bring to light the relationship of such factors as age, sex, nationality, and occupation to tuberculosis.

In the spring of 1928 the first Early Diagnosis Campaign was held. This country-wide educational campaign, conducted each spring for nine years, has for its objective the detection of tuberculosis in its early forms. These campaigns have encouraged the use of the tuberculin test and the x-ray among school children, and have been instrumental in finding early cases of tuberculosis when treatment could be given in time to save many lives. In Massachusetts a ten-year program was started in 1924 by the State Department of Health for the detection of tuberculosis among school children, the most extensive project of this kind ever undertaken.

And after recovery—what? That is another problem tuberculosis associations are working on. In New York City, back in 1913, the first workshop for arrested cases of tuberculosis was opened. At the Altro Work Shop, men and women are successfully engaged in garment making. To prepare tuberculosis patients to return to work, many sanatoria conduct classes for study and well-rounded programs of rehabilitation have been worked out in many parts of the country.

Utopia may be a long way off, but Dr. Thomas Parran, Jr., Surgeon-General of the United States, recently said, "Tuberculosis *can* be wiped out in our nation."

Why not work optimistically toward that goal? In 1907, when the first Christmas Seals were sold, 179 persons out of every 100,000 population were dying from tuberculosis; now less than 60 per 100,000 are dying. Certainly the links in the nation-wide chain of tuberculosis control that have helped to save these lives must not be allowed to weaken. Other links must be added. Let us hope that before the next thirty years have passed, the chain will be so strengthened that the new generation will see Doctor Parran's prophecy come true.

WHAT IS GOOD TO EAT?*

By Thurman B. Rice, M.D.

Who originated the idea that those things you like are bad for you and those things you do not like are just what you need? Appetite surely must have been developed through the ages of evolution as a guide by which the various animals were able to choose their food. It must have served those animals well because otherwise they would have become extinct in the tremendous struggle for existence. Surely, the animals which did not know what was good for them to eat are no longer with us. Surely, the fact that man is here and that he is on the top of the heap is proof enough that his appetite and instincts having to do with food must have been reliable for the most part at least.

Now come a lot of people who would have us believe that these instincts are not at all to be trusted. They would have us eat a great many dishes which we detest simply because these dishes contain certain vitamins, minerals, or proteins. They would have us refrain from foods which we desire most heartily because they say they are too fattening, are lacking in something or other, or possibly are hard to digest. We are willing to grant that times have changed and that there is need that some of the instincts be held in check, but in the main we still insist that appetite is the most fundamentally correct of the many methods of choosing food—provided, of course, that the instinct has not been distorted by false teaching, or practices which are definitely injurious.

---

* From the Department of Bacteriology and Public Health, Indiana University School of Medicine.

Printed in *Food Facts*.

An example of an instinct or appetite that has needed control recently is the strong desire for sweets which is nearly universal. In a state of nature sugar is not easily procured. It is, however, a most important food ingredient. Children in particular crave sweets because they are quick and rich sources of energy, and children use a lot of energy. The pickaninny in the cane brake twists a stalk of sugar cane and sucks the juice. The lad in the northern states bites off the bottoms of clover blossoms and robs the nest of the bumble-bee—or at least he used to do so before he was so well supplied with sugar at the table. Nature has set her young animals on the search for sugar. They need it and, therefore, crave it. But man has learned to purify sugar and has made it the most concentrated and pure of foods. Likewise, it is among the cheapest of foods from the standpoint of calories per dollar. We import sugar into our cities by the carload, and use it in a thousand ways. Nearly everyone has learned to like the flavor of sugar and in consequence we tend to eat too much of it. Not that the sugar is bad food. It is not. It is excellent food when eaten in the right amount and at such a time that it does not clog the appetite or make other flavors seem pale by comparison. The instinct is quite all right, but the capacity for satisfying the instinct has got out of hand.

In general, we propose as our premise, that appetite as it exists in a normal individual is a reliable guide to the selection of food. Immediately there will be heard protest. What about appetite for alcoholic drinks, for tobacco, for coffee, and other substances which are commonly supposed to be more or less injurious. All of these are cultivated appetites. Children do not like beer, coffee, tobacco and other similar products, but learn to like them because they want to do the things which adults do. My own children regard coffee as being worse to take than medicine. They were curious to taste beer because they had heard that it was so wonderful. One little sip was enough to convince them that they could do very well, as yet, without it.

On the other hand, there are foods which do not rate so high with the food faddists which are most satisfying to a hungry man or boy. When I was a kid on the farm I liked nothing so much as to hear that mother had a big pot of beans for dinner. Beans and bread! It was a meal that would stand by you. It would stick to the ribs when one was working hard. Yet there are those who will point the finger of scorn at beans. "They are hard to digest," it is said, but I never was sick from eating beans in my life. They are not a very good source of protein, but we did not attempt to get along on beans alone. There was always some meat with them, some bread, and milk to drink. Beans practically never can go wrong because of the way they are cooked. Anyway I like them, and it will take a lot of talk to make me think they are anything but one of the best of foods.

We have heard the lowly potato slandered, but again I like them. It is said that they are too starchy, that they are fattening, that they are white, and God only knows what else. The potato has been of vast service to the world and has filled up the big and little hollow places in boys and girls for lo these many years. Ask any housewife how she would like to get along without the lowly tuber, and ask any family of kids whether they would miss them or not. If creamy mashed potatoes with a lot of yellow butter is not food for the gods, then I am no connoisseur of the good things of the earth. I have never been made sick by potatoes, never had them served spoiled, never found them hard to digest, and so far as I can see have had no trouble for lack of vitamins.

The protein of corn is not a perfect protein, it is said. I do not care if it is not. I like corn bread, fritters, green corn, hominy, and corn-meal mush. When the family at our house sits down to a meal of corn bread, milk, and butter, we know God is in his Heaven and that all is right with the world. In case I get to worrying about food deficiency at such a time—which I do not—I remember that this country became great on a corn diet. Those hardy pioneers could not always have their spinach and carrots, but they did pretty well. Maybe we ought to imitate them a little more.

My children—and they are sturdy specimens—like bread and jam, bread and butter, bread and syrup. They go for pie! Horrors! Does a teacher of health eat pie and permit his children to eat pie? Yes, he does and sets them the example. If there is anyone who can explain why a good piece of pie made from delicious fruit is bad food, I should like to have him rise and explain. Parents commonly require their children to eat their vegetables before they can have more bread and jam or pie, and there is a certain reason for doing so. Children really should learn to eat a wide variety of things rather than just those which are tastiest and best. (Shall we say best? I think so.) Consequently, there must be some sort of regulation or there would not be enough dessert to go around, but in the main we insist again that there is probably no better guide to correct diet than the unspoiled instincts and appetite of a healthy child of ten. And does he not have a lot of fun eating when his elders leave him alone?

Yes, there must be parental control at the table, and there must be research in food and food requirements. These efforts serve the purpose of guiding us to the right foods in order that we may be healthy and happy. But parents have been wrong in their ways of rearing children, and distinguished scientists have been wrong in their pronouncements concerning diet. If the instincts and appetites of the human race had been very much wrong, the human race would long since have become extinct. Instead the race is the finest product of all evolution. Draw your own conclusions.

GIFT OF ONE HUNDRED THOUSAND DOLLARS: FOR STUDY OF VOLUNTARY INSURANCE PLANS

A gift of $100,000 to the American Hospital Association for the study and development of voluntary hospital insurance was announced by Edwin R. Embree, president of the Julius Rosenwald Fund, at the annual meeting of the Fund recently held in Chicago. This plan, known as group hospitalization, enables persons of moderate means to secure hospital care by payments of from $6 to $12 per year without recourse to charity.

The program of the American Hospital Association will be carried forward through a special Committee on Hospital Service, of which C. Rufus Rorem of Chicago becomes executive director. The chairman of the committee is Dr. Basil C. MacLean of Rochester, New York, and other members are: Dr. R. C. Buerki, Madison, Wisconsin; Dr. S. S. Goldwater, New York City; Monsignor Maurice F. Griffin, Cleveland, Ohio; and Dr. Claude W. Munger, president of the American Hospital Association.

The work of the Committee on Hospital Service includes two phases: First, advice and consultation to existing plans and those being formed concerning actuarial data, benefits, method of organization, public relations, annual subscription rates; second, relations of hospital service plans to the medical profession, public welfare activities, state departments of insurance, private insurance companies, hospital administration, and hospital accounting. This program is a continuation of the activities of the American Hospital Association since 1933.

Doctor Rorem, who is a certified public accountant, was formerly associate professor at the University of Chicago and is the author of a university text in accounting, as well as several volumes dealing with the economic and financial aspects of hospital and medical care. Since 1931 he has been associate director for medical services of the Julius Rosenwald Fund and since 1933 has been consultant in group hospitalization to the American Hospital Association.

Enrollment in group hospitalization plans is now approaching one-half million employed subscribers and dependents, with more than 150,000 participating in the three-cents-a-day plan for hospital care in New York City. Plans which have enrolled more than 25,000 employed persons are those in Rochester, New York; Cleveland, Ohio; Washington, D. C.; Minneapolis and St. Paul, Minnesota, and Dallas, Texas. Other plans with 5,000 or more subscribers and dependents are those in New Orleans, Syracuse, St. Louis, San Antonio, Houston, Memphis, Sacramento, Newark, Charleston and Bluefield, West Virginia, Kingsport, Tennessee, and a state-wide plan for North Carolina. Nonprofit city-wide hospital service plans have been established or are being organized at the present time in Chicago, Buffalo, Albany, Louisville, New Haven, and Boston.

TWENTY-FIVE YEARS AGO[†]

EXCERPTS FROM OUR STATE MEDICAL JOURNAL

Vol. IX, No. 12, December, 1911[*]

From Some Editorial Notes:

Salvarsan.—It is unfortunate that there is such a prevailing opinion that salvarsan has displaced mercury, and that one injection of the new preparation will cure a large percentage of syphilitic infections. It is undoubtedly true that salvarsan may abort early lues, will usually clear up syphilitic eruptions quicker than mercury, works well where the latter drug fails, and is a specific in malignant syphilis. Nevertheless, it is seldom that one injection has the desired effect. . . . —H. M.

* * *

Cancer.—In spite of recent valuable additions to our knowledge of cancer, the treatment remains virtually the same, radical removal of all surgically accessible growths. There is no present indication of change. So far therapeutic progress has been achieved mainly within the domain of surgery and has consisted of the development of technical methods all having a common end, complete removal. . . . —M. S.

* * *

Specialism.—An eminent gentleman spoke disparagingly of the modern tendency toward specialization in the healing art. Said he: "The day of the good old family doctor is, or will soon become a thing of the past; now every portion of the body is covered by a specialty, except the umbilicus. And even that," concluded the learned one, "is in imminent peril." . . .

Our contention is that the tendency to specialize was the inevitable result of problems repeating themselves which called for original thought and recurrent experience, and that without it scientific medicine must have been impossible. . . .

Annual Meeting of the Medical Society, State of California.—The attention of the members is called to the fact that the annual meeting of the State Society will be held in April, 1912, at Hotel Del Monte. The Committee on Scientific Work is now considering the matter of arranging the program and those desirous of presenting papers are respectfully requested to send their titles as soon as possible to Dr. William Ophüls, Chairman Committee on Scientific Work, Lane Hospital (corner Clay and Sacramento streets), San Francisco. . . .

From an article on "The Significance of Pelvic Pain" by Ray Lyman Wilbur, M.D., San Francisco.

Any physician who deals much with sick women and who has not had his senses somewhat dulled by the constant repetition of the complaints of pain in the pelvis, back, legs and abdomen that daily assail him must be without the normal type of nervous system. Experience has shown him that so many of these pains disappear or are no longer spoken of as soon as health follows anemia, rest follows fatigue, comfort follows worry, happiness follows gloom, or normal peristalsis of the bowel is established, that he unconsciously discounts most of the assertions made to him and often looks upon them merely as hysterical or neurasthenic manifestations. Yet pain, as we all know, is our greatest friend whenever the peritoneum is threatened, and we know what a prominent part in acute illnesses and early deaths the peritoneum plays. Where would modern abdominal surgery be were it not for pain? Its triumphs would be of a very different sort than they are today. . . .

BOARD OF MEDICAL EXAMINERS OF THE STATE OF CALIFORNIA[†]

By Charles B. Pinkham, M.D.
Secretary-Treasurer

Board Proceedings

"Officers of the State Board of Medical Examiners retained their offices here after an election at the annual meeting here. Dr. William R. Molony of Los Angeles president; Dr. Clark L. Abbott of Richmond, vice-president; and Dr. Charles B. Pinkham of San Francisco, secretary-treasurer, are the officers. Doctor Pinkham has held his position for twenty-four years. . . ." (Associated Press dispatch, dated Sacramento, October 21, and printed in the San Diego *Tribune,* October 21, 1936.)

The following changes in status of licentiates were made by the Board of Medical Examiners at the annual meeting held at the State Capitol, Sacramento, October 19 to 22, 1936:

Isaac S. Clark, M. D., Long Beach, narcotics, on October 21, 1936, placed on probation for five years without narcotic privileges or possession.

Hugo W. Foss, M. D., Los Angeles, narcotic violation. Licensed revoked on October 21, 1936.

George W. O'Donnell, M. D., San Francisco, alleged illegal operation. License revoked on October 21, 1936.

Frank J. Parizek, M. D., Los Angeles, narcotics, on October 21, 1936, placed on probation for five years without narcotic privileges or possession.

Lee Edward Smith, M. D., Oakland, violation of probation re narcotics. Licensed revoked on October 21, 1936.

Wade H. Walker, M. D., Long Beach, narcotic violation. Licensed revoked on October 21, 1936.

George H. Wymann, M. D., Los Angeles, penitentiary sentence re abortion. License revoked on October 21, 1936.

The hearings on the following were continued to the next meeting of the Board, to be held in Los Angeles: John E. Cummings, M. D., Los Angeles; Henry L. Gardner, M. D., San Francisco; Oscar Charles Long, M. D., Brawley; Francis W. Steddom, M. D., Los Angeles; George E. Watts, M. D., Los Angeles; Thomas D. Wyatt, M. D., Redding.

The following were dismissed: Quinter O. Gilbert, M. D., Oakland; Samuel A. Twain, M. D., Berkeley.

News Items

"Hysterics and a fainting spell by a woman witness yesterday threw out of gear the Superior Court trial of fourteen women as alleged operators of a gigantic Pacific Coast illegal operations syndicate. . . . Mrs. Gladys Duckworth of Santa Monica, a former patient of the operation syndicate, was unable to tell her story to the jury because of an emotional outbreak brought on, she explained, by word that she had just been discharged by her employer, a Santa Monica dentist. She said the dentist objected to her agreement to testify in the case and had communicated her discharge by telephone as she waited in an anteroom to the court. . . . A ten-minute recess was ordered and she returned to the anteroom, where she toppled to the floor in a dead faint as her name was called again. . . . When she had been restored to consciousness, Deputy District Attorneys Verne Ferguson of Los Angeles and J. J. McMahon of San Francisco informed her she need not testify at all unless she wished. . . . Meantime her divorced husband, Frederick Duckworth, gave brief testimony, which was to have followed Mrs. Duckworth's as corroboration of her statement that she became critically ill after an operation in 1935 at the alleged Los Angeles Clinic of the organization. . . . Her testimony, Ferguson said, will be similar to that given at yesterday morning's session by Mrs. Dorothy Woods of Long Beach. Both stories, the Prosecutor informed the Court, will substantiate the prosecution claim that leaders of the alleged

MORE LITERS OF BAXTER'S SOLUTIONS HAVE BEEN USED THAN ALL OTHER KINDS COMBINED

There is one final test for intravenous solutions which no laboratory can apply. The test is made by you who use solutions . . . its measure is your acceptance of those solutions.

After all is said and done, what test is so conclusive as that of actual use? All the precautions, all the safeguards and tests made by laboratories are for one purpose — to assure you always of *complete* satisfaction. The real measure of the success of any laboratory in achieving this purpose is your acceptance of its products.

Judged by this very practical test, which takes *all* the factors into account, Baxter's Solutions are first in the field of intravenous therapy. For Baxter's Solutions in Vacoliters have been used by more doctors, in more hospitals, and in greater volume, than all other ready-to-use solutions combined! May we serve you?

BOARD OF MEDICAL EXAMINERS

(Continued from Front Advertising Section, Page 30)

Attorney Vernon Ferguson of Los Angeles seven canceled $1,000 checks as payment she had made to Rankin from January to July, 1935, for the San Diego Clinic. She said that late in 1934 she learned from druggists who had been referring patients to her clinic that 'a bunch of big doctors are coming to town.' The syndicate's offices were established, she said, on January 1, 1935. On January 25, she continued, Byrne visited her establishment, displayed his badge and threatened her with jail. He told her, she testified, that the affair could be adjusted if she would visit him and Rankin in Los Angeles, prepared to 'team up' with his organization. . . ." (Los Angeles *Examiner,* October 15, 1936.)

"Held on suspicion of drunk driving, Dr. Robert V. Baker, resident physician at Olive View Sanitarium, was in the prison ward of the General Hospital yesterday. Witnesses told police that on Friday night they followed the doctor's car from Burbank to San Fernando Road and Vineland, observing his assertedly erratic driving. At the intersection, they said, his car crashed head on into a sedan in which Mr. and Mrs. Leslie A. Wright of Saugus and Wright's mother were riding. All persons involved in the crash were cut and bruised." (Los Angeles *Examiner,* September 27, 1936.)

"Dr. Ernest L. Hildreth of 2007 West Sixty-ninth Street, yesterday was found guilty by Municipal Judge Aggeler on a charge of drunk driving. According to the testimony of Officers Hoover and Benson of the State Motor Patrol, the physician sideswiped their machine last August 31, near Slauson Avenue and Byrnhurst Street. . . . " (Los Angeles *Times,* September 26, 1936). The name Ernest L. Hildreth does not appear in the 1936

"Dr. M. E. Eastman, sixty-two, of Pleasanton, yesterday decided not to risk trial on three felonies and pleaded guilty to a charge of selling stock prior to the incorporation of the concern involved. . . . In addition to the charge to which he confessed, he was to be tried for grand theft and selling stock without a license. His arrest grew out of the sale of $1,000 stock in his Tuberculosis Foundation at Las Vegas, Nevada, to Mrs. Faye E. Bradley, 2206 East Thirty-second Street, Oakland. . . ." (San Francisco *Examiner, East Bay Edition,* October 2, 1936.)

"Hundreds of 'case records' of women throughout the State who assertedly were victims of an alleged illegal operation ring, were introduced into evidence today at the opening of the third week of the trial of thirteen persons charged with participating in the alleged ring. The opening wedge in the State's effort to introduce the 'case records' was made through the testimony of pretty Dorothy Wood, 18, of Long Beach. Under questioning in Superior Judge Arthur Crum's Court by Deputy District Attorney V. L. Ferguson, the girl declared she signed her name to a blank card when she started preliminary steps toward an abortion. It was brought out through the questioning that when Miss Wood's card was discovered among hundreds of others, after the raids that led to the charges against the thirteen persons, the card bore a notation that the operation was necessary to save her life because she suffered from an acute abdominal condition. Deputy Ferguson attempted to show, through Miss Wood's answers,

When Steers Had Long Horns

THE medicinal value of the glands of internal secretion was not recognized.

But times have changed, as well as cattle. Now, the therapeutic value of certain gland products is definitely established and each year adds to our knowledge in this important field of therapeutics.

To the physician prescribing gland products we urge specification of "Wilson," because it connotes a product made at the source of supply from fresh glands, processed promptly, with the aim of conserving maximum hormone activity, in a laboratory devoted exclusively to the endocrine field.

BOARD OF MEDICAL EXAMINERS

(Continued from Preceding Page)

that the notation was made 'in case something happened to her.' Miss Wood also testified, in identifying her signature on the card at today's court session, that she also had identified it when shown her by officers several weeks ago. Then back to the witness stand went Detective Lieutenant George J. Engler (San Francisco Police Department), leader of the raids and one of the principal state witnesses. He started what was expected to be an hour-long introduction of the case records. . . . A fat, black book, which purportedly contains the names of physicians who referred abortion cases to an illegal operation ring, today was said to be attracting as much interest in medical circles as Mary Astor's famed diary did in film circles. The only section of the book to be made public referred to a hospital where an asserted abortion was performed. Belief was expressed in court circles that attorneys for the thirteen defendants would demand that the entire book be made a part of the court record to show that a large portion of the medical profession condoned illegal operations by referring them to the asserted syndicate. . . . Although the prosecution has not indicated its attitude in the matter, hope was expressed that the diary would be impounded, as was the diary of Film Actress Mary Astor in her child-custody battle with Franklin Thorpe." (Los Angeles *Evening Herald and Express,* October 19, 1936.)

Moreover, public policies are not made up entirely of scientific facts. Facts are only the background; they determine what lines of action are possible. The policies that will actually be adopted depend upon the desires of the people, modified by their understanding of the facts.—National Resources Committee Report, June 15, 1936.

Can you account him wise or discreet that would willingly have his health and yet will do nothing that should procure or continue it?—Robert Burton.

"Is This Product Council-Accepted?"—This is the first question many physicians ask the detail man when a new product is presented.

If the detail man answers "No," the doctor saves time by saying, "Come around again when the Council accepts your product."

If the detail man answers "Yes," the doctor knows that the composition of the product has been carefully verified, and that members of the Council have scrutinized the label, weighed the evidence, checked the claims, and agreed that the product merits the confidence of the physician. The doctor can ask his own questions, and make his own decision about using the product, but not only has he saved himself a vast amount of time but he has derived the benefit of a fearless, expert, fact-finding body, whose sole function is to protect him and his patient.

No one physician, even if he were qualified, could afford to devote so much time and study to every new product. His Council renders this service for him, freely. Nowhere else in the world is there a group that performs the function so ably served by the Council on Pharmacy and Chemistry and the Council on Foods.

Mead Johnson & Company coöperate with both Councils, not because we have to, but because we want to. Our detail men can always answer you, "Yes, this Mead Product *is* Council-Accepted."

Physiologic Effects of Benzedrine.—Myerson, Loman and Dameshek (*Am. J. Med. Sci.,* October, 1936) report on the physiologic effects of the sympathomimetic amine, benzyl methyl carbinamine ("Benzedrine") in adult humans. Administered parenterally in varying doses, the average rise in systolic blood pressure was 29 millimeters of mercury. The height of blood pressure was attained in an average time of forty-six minutes and reached its normal level two to eight hours after administration. Orally, in rather large doses (40 milligrams), the blood pressure increases were nearly identical with those after parenteral administration except that the action was delayed. Atropine when combined with Benzedrine markedly

enhances its effects. A parasympathetic stimulant, mecholyl, when given with or during the period of Benzedrine action, exerted its depressor effect over a shorter period, temporarily nullifying the action of Benzedrine without being antagonistic to its continued prolonged action. Benzedrine has a definite stimulating action on the central nervous system as shown by the shortening of sodium amytal narcosis. A marked rise in both white and red blood cells, with a lowering of color index, was usually found. These increases were apparently mechanical and of no clinical significance. The authors state that they did not observe an increase in basal metabolic rate or blood sugar. Reference is made to the good effects of Benzedrine in lowered mood and in certain fatigue states; these are the subject of a separate study, as is the drug's action in relaxing gastro-intestinal spasm.

Did You Pay Your Share of Taxes?*—Taxes collected in California last year "averaged" $246.50 for each of the two and a half million persons in this State who are employed for wages or salaries or who receive an income from some other business or occupation.

If you are an "average" person in this group, with an "average" income of $1,400 a year, then "your share" of these taxes collected last year is indicated to have been $246.50.

Now if you are actually earning about $1,400 a year (or $120 a month), is is very likely that you will say: "These averages must not apply to me. I don't remember paying any $246.50 in taxes last year. This can't be my share."

Of course, no one sent you an official bill for that amount. You actually may have paid more or less, depending on where you live and how you spent your income. But if you will study the ninety or more varieties of taxes levied in California by the local, state, and federal governments, and trace these down to the ultimate consumer or *actual* taxpayer, you will discover that you did pay nearly as much as these averages indicate to be "your share."

Taxes Collected in California—1935

Average for Each Employed or Otherwise Gainfully Occupied Person

			Your Share
Local taxes on property			$ 91.88
County taxes on property		$27.20	
City taxes on property		36.98	
District taxes on property		27.70	
State taxes			61.23
(*a*) Retail sales tax		$22.59	
Gasoline tax and auto license		18.72	
(*b*) Gross receipts of public utilities		13.30	
Liquor taxes and licenses		2.13	
Other state taxes		4.49	
Federal taxes			93.39
TAXES ON NECESSITIES		$31.09	
(*c*) Hogs, wheat, cotton, etc.	$13.37		
Gasoline, oil, etc.	5.25		
Autos, bodies, tires, etc.	2.12		
Other necessities (taxes and duties)	10.35		
TAXES ON LUXURIES		$28.92	
Tobacco	$13.61		
Liquor	11.33		
Other taxes and duties	3.98		
TAXES ON INCOMES AND INHERITANCES		$33.38	
Total taxes			$246.50

(*a*) Average under old sales tax law, before exemption of food.
(*b*) Not in effect during 1936.
(*c*) Processing taxes not in effect during 1936.

Only about 10 per cent of these were *direct* taxes which you realized you were paying, or remember. The remainder were hidden and indirect taxes, concealed in the prices of things you bought, and in your cost of living.

Study these averages indicating "your share" of taxes collected last year, keeping in mind that if your income was higher or lower than $1,400 a year, "your share" was proportionately higher or lower.

(Continued from Preceding Page)

Take a few of the larger items of tax collections, and see how they apply to your own case. You will have to modify them, of course.

If you have an income of $1,400 or less you probably did not pay any of the direct taxes on corporation or personal net incomes or inheritances. But you can take out all of these forms of State and Federal taxes, and it will only reduce the average somewhere between $35 and $40.

That still leaves well over $200 in taxes which are paid by every one, and mostly hidden in the cost of living.

Local Taxes:

Start with the local property taxes. Your indicated "average" share of these taxes is $91.88. If you own a home or other personal property with an assessed value of $2,000, you actually paid about $70 in direct taxes. If you rented a house, apartment, or a room, you can figure that 25 per cent or more of your rent bill was for property taxes. It amounts to about the same either way.

When you have figured these up, you may be short of the $91.88 average. But remember that the industrial and business enterprises which provide all of the necessities you buy, also paid property taxes. Do you think that the manufacturer, the trucking company, or your butcher, or grocer or department store forgot to add these and other taxes into the prices of the things you bought? Certainly not. They would not stay in business long if they did.

So even if you do not own *any* taxable property, you probably paid more than your indicated share of these local property taxes. Why? Because most of your income was spent for rent, food, and clothing, and most of our taxable industrial property is used to supply these and similar necessities.

State Taxes:

Your indicated "average" share of State taxes was $61.23. That was only 25 per cent of the total of all taxes collected last year.

You may be surprised to find that the general retail sales tax which was in effect in this State last year, provided only 9 per cent of the total tax revenues collected from California residents. Your indicated share of the retail sales tax was $22.59. Possibly this is the only tax you remember paying. It was a *direct* tax, and it was not hidden in the prices of things you bought.

Last year family budget experts at the University of California figured that the retail sales taxes for a family of five with a $1,500 a year budget, amounted to $21.64, of which $12.12 was tax on foodstuffs. This year since foodstuffs have been exempted from the tax, the same family will pay only $11.41 in sales taxes. This State tax is no longer a general sales tax. Under the new law persons with higher than average incomes now pay a much larger share of this tax than they did last year.

Your indicated share of the State tax on gasoline, and the automobile license fees, was $18.72. If you or your family did not own a car, you can subtract most of this from your "average." But if you did operate a car, then you probably paid more than this amount of taxes. If you drove a car 10,000 miles last year, the three-cent State tax on gasoline alone would amount to about $24.

Your share of the State taxes levied last year on public utility gross receipts was $13. Most, if not all of these taxes were passed on to the users of electricity, gas, telephones, railroads, and busses, hidden in the prices paid for these services.

You are the only one who knows, of course, whether you paid any liquor taxes, or more or less than your indicated share of $2.13 in State taxes on liquor last year. Whatever it was, you can figure that it will be about two and one-half times as much this year under the new laws.

Most of the remaining State taxes, of which your indicated share was $4.49, were inheritance, and bank and corporation franchise taxes. Most but not all of these can be subtracted from your average.

Federal Taxes:

Your indicated "average" share of Federal taxes last year was $93.39. As already noted, your $33.38 share in that total which was collected from corporation and individual incomes, inheritances, estates, etc., was mostly paid by persons with incomes over $1,400 a year.

FRANK SCHMIDT
Superintendent

But the other 65 per cent of Federal taxes were excise and similar taxes on articles and services used by all consumers. Your share of these is indicated to be $60. You may be surprised to see that this is practically equal to your share of all State taxes combined.

Your indicated average share of the Federal processing taxes levied last year on hogs, wheat, cotton, sugar, rice, and peanuts, totaled $13.37. Whether you paid more or less than this depends on the size of your family.

If you own an automobile, you paid a Federal tax of 4 cents a gallon on lubrication oil, 1 cent a gallon on gasoline, 2¼ cents a pound on tires, 4 cents a pound on inner tubes, 2 per cent on accessories, bodies and parts. The average of $7.37 is low in this case.

Excise taxes and duties on other necessities averaged $10.35. This includes the excise taxes on electricity, matches, toothpaste, soap, chewing gum, flour, and scores of others, such as telephone and telegraph messages and safety deposit-box rentals. None of these alone is very big, and they were hidden in the prices you paid, *but you paid them.*

Your share of the Federal excise tax on tobacco was $13.61, but if you smoked a package of cigarettes a day, you actually paid $22 into the treasury on that item alone. Your share of the Federal taxes on liquor was $11.33. Other luxuries taxed were playing cards, perfumes, cosmetics, jewelry, radio parts, sporting goods, and admissions to theaters, boxing contests, or football games. Anywhere from 10 to 50 per cent or more of the prices you paid for these luxury items were for taxes.

Conclusions:

What does this mean? It means that those who think that taxes are paid by "someone else," or that the average man or woman has no concern in the cost of government, are fooling themselves.

It means that you did pay most, if not all, of your indicated "average" share of taxes last year, even though they may have been so hidden and indirect that you did not realize it.

For Acidity and Allied Conditions, we suggest ADAMS SPRINGS MINERAL WATER

● MANY physicians recommend the water in conjunction with the treatment of stomach, liver and kidney trouble.

ADAMS MINERAL SPRINGS is one of the seven known iron and maganese bi-carbonate springs in the world, and the only one in Western America.

It is not a cure-all, but it overcomes acid excesses in the body, and is a very mild but wonderfully effective eliminator. The bowels function without spasm, the kidney output is greatly increased, and there is *marked* drainage of bile from the gall bladder and liver.

There is also some constitutional upset for a few days, particularly in gall bladder cases. But this is soon over and your patient begins to show improvement and is now in condition to profit by any medication you may prescribe. If the case is an operative one, you have improved your patient and made of him a better risk.

We will be pleased to cooperate in any way whatever, and samples of water are yours for the asking.

Therapeutic Value of Lump-Sum Settlements for Industrial Neuroses.—There is little or no therapeutic benefit in cash settlements paid to injured workmen who have traumatic neuroses, according to an investigation made recently by Carl Norcross, Ph.D., of the Rehabilitation Division of the New York State Department of Education. Results of the investigation have been published under the title "Vocational Rehabilitation and Workmen's Compensation," and the report is a follow-up study of 322 workmen's compensation cases throughout New York which were closed by a lump-sum settlement of $1,000 or more.

It has been generally accepted in both medical and workmen's compensation circles throughout the country, says the report, that a cash award would help to cure a neurosis. "A careful investigation made a year or more after the settlements has convinced us that the value of a cash award is vastly overrated," writes the author. "It is the settlement of the case, the actual ending of the litigation, which is of value. Whether the final compensation award is paid in one lump or extended through a number of installments makes little difference to the claimant's condition."

The investigation disclosed that 16 per cent of the men had lost a large share of their compensation through unwise expenditures. The men who had no losses were found to have dissipated their funds much more rapidly than they would have under an installment system. Both be-

Cocomalt
A DELICIOUS FOOD DRINK
CHOCOLATE FLAVOR

RICH IN IRON,
CALCIUM, PHOSPHORUS,
VITAMIN D—

Doctors find many uses for this delicious food-drink

THE use of Cocomalt by the medical profession continually increases. This delicious chocolate flavor food-drink has a rich content of Iron, Calcium, Phosphorus, Vitamin D. An ounce of Cocomalt (the amount used to make one glass) provides 5 milligrams of Iron in easily assimilated form. Three glasses provide 15 milligrams of available Iron, the amount recognized as the average daily nutritional requirement.

Each glass of Cocomalt in milk also provides .33 gram of Calcium, .26 gram of Phosphorus, 81 U.S.P. units of Vitamin D.

Helps bring sound sleep

Cocomalt is easily digested, quickly assimilated. It is delicious hot or cold, tempting to young and old alike. Taken hot before retiring, it helps induce sound, restful sleep.

Sold at grocery, drug and department stores in ½-lb. and 1-lb. air-tight cans. Also available in 5-lb. cans for professional use, at a special price.

FREE TO DOCTORS:

We will be glad to send a professional sample of Cocomalt to any doctor requesting it. Simply mail this coupon with your name and address.

(Continued from Preceding Page)

cause there was found to be a wastage of compensation funds, and because there appeared to be no therapy in the settlements, the author has recommended that lump-sum settlements be discontinued.

Doctor Norcross makes a number of recommendations for improving the handling of neurotic cases in the workmen's compensation rooms. He urges that cases be given a more prompt and careful handling. The average neurotic case is open in the workmen's compensation division for nearly three and one-half years, it is said, and much of the delay is unnecessary.

The author states that neurotic conditions grow as cases are delayed. He also points out the dangerous policy of permitting claimants to read their own medical reports, or to be present when physicians are testifying, especially in contested cases where there is a difference of opinion.

In New York a compensation case theoretically may always be reopened. The report suggests that it is a poor policy to let neurotic claimants know that when their money is spent that they may try to reopen their cases. The author believes that one of the evils of the existing New York system in non-schedule cases is that claimants must be willing to accept a lump-sum settlement. After a fair offer is made, the neurotic claimant may procrastinate indefinitely by refusing such a settlement. Thus the case is delayed, and the patient's mental condition may become worse. The remedy suggested by the report is that the referee, acting on competent medical advice, fix a fair settlement and close the case, with the award being paid in biweekly installments.

To overcome any prejudice the claimant may have toward the insurance company, it is suggested that the money be paid to a state-administered trust fund, which already exists in New York. The carrier could close the

Convalescents Require the High-Caloric Diet

COMMUNICABLE DISEASES

Disease	*Incubation Period* (average)	*Isolation Period* (average)
Chicken Pox	12-16 Days	3-14 Days
Diphtheria	2-4 Days	After 12th Day—until cultures negative
Epidemic Meningitis	1st Week	Until cultures negative
Measles	2nd Week	Until 5 days from onset rash
Mumps	3rd Week	Duration of Swelling
Poliomyelitis	3-10 Days	21 Days
Rubella	3rd Week	Duration of catarrh and rash
Scarlet Fever	1st Week	After 21st Day—until cultures negative
Whooping Cough	2nd Week	Until 4 weeks from onset whoop

From American Journal of Public Health—March, 1927

INFECTIOUS FEVERS deplete the child's vitality. It is an exhaustion comparable to fasting. Convalescent children show a low metabolism for several weeks following the disappearance of the fever. The low metabolism is the consequence of generalized cellular damages.

When the infection clears, activity is curbed and rest periods instituted. The child is ready to gain. The problem is to bring about sufficient intake of food. The initial diet consists of small portions of each food prescribed and the amounts are gradually increased.

The high caloric diet is indispensable. It is made possible by reinforcing foods and fluids with Karo. Every article of the diet can be enriched with calories. A tablespoon of Karo provides 60 calories. Karo is relished added to milk, fruit and fruit juices, vegetables and vegetable waters, cereals, breads and desserts. Karo consists of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor), not readily fermentable, rapidly absorbed and effectively utilized.

case on its books, and the claimant could be told his case is definitely closed but that he would get all his money, regardless of his state of health. The patient would not have to remain sick to get his award.

Provision is made for permitting the claimant to get an advance on his compensation for any necessary purpose, including rehabilitating himself on a farm or in a small business.

Copies of the report may be secured through the publisher, The Rehabilitation Clinic, 28 East Twenty-first Street, New York City. Price, $1.

The Early Diagnosis of Cancer.—Cancer is curable in the early stages; however, the early stage cannot be diagnosed by the patient, but can be discovered by the alert family physician. *The keystone of cancer control is early and correct diagnosis.*

The early signs or symptoms of cancer should be familiar to the laity. When they appear, the advice of the family physician should be sought without any delay.

When chronic ulcers of the skin become hardened, it may mean a beginning cancer.

When a pigmented mole turns black, it probably is turning into a cancer.

When keratoses or scaly elevations or warts of the skin become moist, it is an indication that the usually benign character of such lesions is undergoing malignant changes.

When leukoplakias or white, thickened patches on the mucosae begin to crack open, they must be immediately treated, as this change indicates malignant transformation.

When difficulty in swallowing is felt, a cancer may be forming in the esophagus. An x-ray examination and inspection with the esophagoscope will immediately enable a correct diagnosis to be made.

When a cough without any other signs appears, x-ray pictures of the lungs should be taken immediately, as cough is often the first sign of cancer of the lung.

When a chronic breast inflammation shows hard nodes, an x-ray picture of the breast gland should be taken. If the lesion is shown to be diffuse, an excision, under local anesthesia, should be performed and all the tissue examined microscopically, to rule cancer out or in.

When loss of appetite seems to come out of a clear sky, or indigestion has existed for a long time, clinical and x-ray examinations of the stomach must be made without delay, as the symptoms may mean cancer.

When hoarseness or huskiness of the voice sets in, cancer of the larynx should be feared. Examination with a throat mirror will immediately show whether a tumor has formed.

When blood is passed from the genital organs, the bladder or the rectum, examinations with special instruments are called for to determine the true significance of the bleeding.

During the climacteric, an increase in the amount and duration of the monthly flow or the appearance of bleeding at irregular times is especially significant of cancer.

When persistent pain takes place in a bone, x-ray pictures should be taken. Such pain frequently means the onset of cancer.

When a discharge appears, especially from the female genital organs, we must remember that such signs and symptoms may mean impending cancer. Immediate examination will enable the physician to determine whether a new growth is developing.

Therapeutic measures for the arrest of cancer have been developed to a high degree. The methods consist of surgery, either with the cold knife or with the electrotome, and of radiation therapy with roentgen rays and radium. No other methods are now known to exist by which cancer can be totally eradicated. Yet these remedies will remain impotent unless early diagnosis furnishes the surgeon or radiologist a fairly localized and beginning cancer. When diagnosis is obvious, most cancers are already in the incurable stage. Yet, in most cases, diagnosis is possible when the disease is curable by modern methods. The

difference between early and late diagnosis means the life of a patient. There is no other major cause of death in which early diagnosis occupies such an important position.

The difficulties in the diagnosis of cancer are very great, probably greater than with any other group of diseases. Every organ and tissue of the body may become the primary seat of a malignant growth. Therefore the diagnosis calls upon the resources of every one of the medical specialties and general medicine and surgery.

Cancers may be accessible or inaccessible. They are accessible if they can be seen or if they can be exposed to view by speculums and endoscopes. The inaccessible cancers are those of the internal organs, as the cavity of the skull, the chest, the abdomen, the bones, etc. Yet modern medicine has bent all its energies on improving its diagnostic aids by the construction of artificially lighted instruments known as endoscopes which may be inserted into the body canals and hollow organs to enable the physician to inspect these regions. Modern x-ray diagnosis, also, has resulted in depicting lesions in these otherwise inaccessible cavities and thus aids the physician in the diagnosis of disease conditions in otherwise inaccessible regions of the body. The inaccessible or internal cancers outnumber the accessible or external.

Cancer in the beginning stage or beginning nodule is silent—it gives no local or general subjective symptoms until it reaches a certain stage. The suspicion of cancer should be constantly in the mind of the physician and the laity. Cancer-mindedness will thus lead to the discovery of the early cases. A great deal of assistance is given by the fact that cancer rarely develops in a previously healthy tissue, but generally in tissue altered by chronic disease and subjected to chronic irritation. Cancer generally develops slowly and by successive stages.

The above-mentioned signs and symptoms should lead the physician and the layman to think immediately of the possibility of precancerous lesions or impending cancer. The physician should strive to obtain an immediate and correct diagnosis without procrastination. Delay in diagnosis is the best friend of cancerous disease and the greatest enemy of the cancer patient. Precancerous lesions and early cancers are curable.—Editorial from *Physical Therapy and Radiology,* June, 1936.

Home Work By Young Pupils May Have Bad Effects.—Schools of Ohio have begun or are beginning the yearly turn of the wheel of education, and with this recurrent activity again under way, questions arise as to the number of foot pounds (or tons) of home work to be laid on the 2,000,000 pupils subject to its discipline. With increased crowding of the curricula, increased emphasis laid on athletics, and the marked increase in social activities (which have almost reached the "required" stage) there is strong temptation to increase the amount of home work laid on the pupils, and there seems to be ample evidence that there has been much yielding to temptation.

In many of the schools home work is started in the second or third grade. There are few in which the fourth grade is passed without assigned home work. From these beginnings until the day of the diploma is reached, the educational "forcing beds" pile more and more home work on the pupil with each successive grade.

What is the effect on the health of the individual pupil? What is the mass effect on the health of the people?

Unhappily, not much is known about these effects. The casual observer can judge only from isolated cases that come under his eye. It would be well if some thorough research were done to supply the answers. Fortunately, some consideration has been given to the problem through an agency from whose report may be deduced some definite conclusions. The Association of District Superintendents of New York City studied the question in 1929 and formulated these recommendations:

"Quality, not quantity, should be the standard of efficiency in judging the results of home work.

"Compulsory home work should be prohibited for children below the fourth school year.

(Continued from Preceding Page)

"For pupils in seventh-year classes, the maximum time for home lessons should be one hour. In eighth-year classes it should be one hour and a half.

"No home work should be permitted unless adequate explanation has been given in school by the teacher.

"Principals should control the specialists in departmental work and prevent the demand for the preparation of too elaborate notebooks, drawings, maps, or essays.

"In every school some uniform plan should be adopted to regulate the general plan of home study, and throughout all grades teachers should be directed in the use of the study period where such period is utilized."

Another analysis of the home-study problem sets forth that:

"Only work that can be done without help of parents should be assigned.

"Home study should be made a privilege.

"It should not be too difficult.

"Assignments should be made according to capacity and individual needs and for variety in subsequent class work.

"Work should be regular in amount from day to day.

"Half the time should be devoted to written work.

"Assignments should be made when the class is alert and not in the clamor of the last moments of the period."

Home conditions should be taken into account. No one can be expected to do good work in a bedlam of noise. It may be conceded that home study is not undesirable, provided (1) that the home is healthful and reasonably quiet; (2) that the study imposed is not excessive in amount (requiring so much time as to prevent sufficient leisure for recreational and other activities; (3) that it is not too exacting in nature; and (4) that the child know what he is to do and how to do it. To these might well be added: "That it is not started too soon, and that in all ages it shall not be permitted to interfere with required sleep."

However, to approach a real solution of the problem will require some real research work through the combined efforts of health authorities, school management and the school medical service.—*Ohio Health News.*

Some parents actually try to scold health into their children. Health, however, is not understandable to children, at least before they reach twelve years, and when we plead with a child to safeguard his health, he may begin to imagine there is something the matter with him; else, he reasons, why should mother or father talk so much about it? A sense of insecurity may develop. Thinking too much about one's body is enough to bring on sickness—mental sickness at any rate— and it is a very difficult condition to cure.

Many of us are victims of the days when child psychology was not so well understood and when nagging was the nearest our parents ever got to constructive discipline. The fears engendered in those early years left an indelible impression that accounts for peculiarities and prejudices which may handicap us for life. Let us avoid passing on this error to the next generation, by remembering that *nagging never pays.—Florida Health Bulletin.*

Your Share of Federal, State, and Local Government. — The California State Chamber of Commerce is sponsor for the following information:

"The cost of all forms of government for California in the fiscal year 1935 was $900,000,000. What does that mean to you? Do you know what your share of that total was? Do you know how much you paid in taxes? Do you know what was your share of the increase in public debt?

"No one can tell you exactly. That depends on what taxable property you own, where you live, what your income was, how it was spent, and other things which vary with every person.

"But it is possible to obtain some averages which can be used as a measuring stick in determining your actual share of these totals.

"Taxes and other governmental revenues are obtained from the incomes of individuals, directly or indirectly. There are about two and a half million persons in California who received incomes in 1935, either from wages or

minimizes scarring

A FEATURE OF

ANTI-PYREXOL

This most comfortable, and least troublesome dressing for burns may be depended upon to:

1. Relieve pain promptly.
2. Protect denuded areas.
3. Give antiseptic protection.
4. Combat toxemia.
5. Promote prompt healing.
6. Minimize scarring.

Anti-Pyrexol is available through surgical supply houses and drug jobbers in 2-oz. tubes, 1-lb., 5-lb., 10-lb. tins. For technical information address Mona E. Bettin (M. D.), Pathological Laboratories, Roosevelt Building, Los Angeles, or:

salaries, or from other gainful occupations, such as farming, business, or professions.

"If you are an 'average' person in this group your income in 1935 was about $1,400. Your proportionate 'average' share of the total cost of all forms of government for this state was about $360, or a sum equal to one-fourth of your income. Your 'average' share of tax and other revenues collected was $264 and your share of increased debt for that year was $96. If your actual income was above or below that average of $1,400 a year, then it may be assumed that your share was correspondingly higher or lower.

"Keeping this in mind, these figures will give you a fair measure by which to compare *'your share'* of public expenses, with your own individual income and expenses:

* California's Public Expenses

Average for Each Employed or Otherwise Gainfully Occupied Person in This State

How the Money Was Spent	*Your Share*
Relief and social welfare	$106.47
Education	54.97
Interest on public debts	37.43
National defense	29.27
Streets and highways	27.97
Police and fire protection	26.18
Farm recovery (AAA and other)	24.45
General government, state and local	13.51
General government, federal	11.07
All other functions	28.73
Total	$360.05

* California's Public Revenues

Where the Money Came From		
Borrowed (deficits, bond issues, etc.)		$ 96.34
Non-tax revenue (licenses, fees, etc.)		17.21
Tax revenues		246.50
Local (county, city, district)	$91.88	
State government	61.23	
Federal (California's share)	93.39	
Total		$360.05

---

* California's state and local governments and California's share of federal expenditures and revenues during the fiscal year ending June 30, 1935.

JUST THREE SIMPLE FACTS

1. Golden State Evaporated Milk bears the Seal of Acceptance of the Council on Foods, American Medical Association.

2. Golden State Evaporated Milk is NOT irradiated.

3. Every step in the production—from supervised farms to the final delivery to the grocer—is under the critical and exacting eyes of Golden State men.

When it comes time for you to prescribe evaporated milk for infant or child feeding, you can have complete confidence in the nutritional elements, purity and palatability of Golden State Evaporated Milk.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.

2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.

3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.

4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.

5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

DON'T JUDGE THE RANGE OF THIS OFFICE-PORTABLE X-RAY UNIT BY ITS SIZE

BECAUSE the G-E Model "F" Office-Portable X-Ray Unit seems to you so extremely small in size, and its low price places it easily within your means, don't make the mistake of overlooking its practical diagnostic range and ability to produce radiographs of fine quality.

The principle of *complete* oil-immersion of both the high-voltage transformer and the x-ray tube in a single, sealed container accounts for this unusual compactness and high efficiency. Moreover, it makes the outfit absolutely shock proof under all operating conditions.

If you have not yet taken the opportunity to see a practical working demonstration of the Model "F" in your own office, you cannot fully appreciate its possible advantages in your practice.

Fill out and mail this coupon requesting a demonstration. You need not feel obligated in so doing.

In the office or in the patient's home, this unit is practical, convenient and efficient.

☐ Please arrange for an office demonstration of Model "F" Office-Portable X-Ray Unit.

☐ Send literature describing the Model "F" Unit. A-512

"Can chronic arthritis be treated with vaccine?"

MANY OF THE favorable reports of recent years on the treatment of chronic arthritis with vaccine have, undoubtedly been over enthusiastic and uncritical. It remains a fact, however, that a number of competent clinicians and investigators find definite value in such preparations in selected cases; although opinion is divided both as to the type of case and the type of vaccine offering the most promise.

Sherwood's work with various types of vaccine intravenously is particularly encouraging, in-as-much as his results have averaged better than other series reported, while at the same time his cases have been well controlled.

For a review of the literature send the coupon.
